A few months after the morphia incident I was called to this same subject, and found him in a high fever, with extremely rapid pulse and the local symptoms of appendicitis. The local pain was so great that he screamed in his agony. The pulse was so rapid that I could only estimate it as about 180. Recognizing the congestive element, I gave him ergot hypodermically, which relieved the pain in a few minutes, and the pulse dropped to 120. When the pain returned the same treatment had the same result. Thinking the case might demand surgical interference, and preferring to share the responsibility, I called Dr. Roswell Park, of Buffalo, who diagnosed appendicitis, but not yet at the stage for operating. The day that Dr. Park was called the patient and his friends believed him to be dying. A clergyman was called from his pulpit, the good-bys were said by the family, and the patient directed as to the postmortem rites. I continued, however, with my ergot, the patient recovered within a fortnight, and I have not known of his having any illness during the nearly eleven years that have intervened.

OPIUM POISONING.

Here are three utterly distinct conditions, all extreme, in the same subject, having but one common element, vascular dilatation, in the relief of which one drug, ergot, was clearly the effective factor. I have not had an opportunity since the case related to test ergot in opium poisoning, but it would certainly be my first resort were I called to such a case, and I would be grateful to anyone who may have opportunity, if he will try it. I would give one syringeful after another of the solution which I shall describe, giving each one slowly (or, as there is usually a multiplicity of doctors, two might be given at the same time, which would hasten absorption) until there was marked improvement in the circulation, even if it required half a dozen or more syringefuls to accomplish it. I am confident that you may safely rely on this measure alone, except that if the drug was swallowed the stomach should be cleansed.

DRUG HABITS.

I have used ergot for nearly twenty-five years in the treatment of the habit cases, both opiate and alcoholic, and believe it to be by all odds the best treatment, not even excepting the "gold cure." I always immediately and wholly discontinue the habit drug and substitute no other. It may possibly be easier, both for doctor and patient, to gradually reduce the quantity for a few days, giving ergot four to six times a day as a preparation for the final total discontinuance; but I have preferred, as a desirable moral element, to demonstrate to the habitué that neither his habit-narcotic nor any other is necessary to him in any degree. If, in the case of opium addiction, the drug is immediately and wholly discontinued without previous preparation by the ergot, the reaction that occurs during the twenty-four hours following the first twenty-four or thirty-six hours of abstinence is sometimes so appalling that it requires as much moral force on the part of the physician to do his duty as any other situation in which he is placed. He is quite likely to think more of the condition which confronts him than the theory he started to demonstrate; yet, I assure him, he may hold to his theory if he does not forget his hypodermic and his solution of ergot. After that critical twenty-four hours the treatment is easy.

DELIRIUM TREMENS.

In delirium tremens ergot is *the* remedy to calm the mental and physical excitement. A man was brought into my office in such physical and mental agitation that it was with difficulty that I gave the first hypodermic of ergot, and he left the office within an hour as calm and rational as anyone before me. No other drug will so promptly set a man on his feet after a debauch, or so thoroughly clear the head and put one "in condition" after a night's dissipation; and, in the graver sequels of prolonged alcoholic hyperemia of nerve centers, such as paralysis and coma from the pressure of exudates, you will be most agreeably surprised, to put it mildly, at the results of a few hypodermics of ergot. Indeed, to correct the conditions which produce exudation in general and to secure the absorption of the exudates, from simple edema of the feet to serious apoplexy, you can not do better than to give ergot by hypodermic injection. Please treat your next case of edema of the larynx in this manner.

ASTHMA AND OTHER SPASMS.

Since reading the Chautauqua paper, I have been asked as to the danger of producing spasm of sphincters or bladder. In an experience of more than 25,000 hypodermic injections of ergot, in some instances having given ten ordinary syringefuls in twenty-four hours (the equivalent of one-half dram of Squibbs' solid extract, or two and one-half drams of the powdered ergot), I have never observed any such effect; and not more than half a dozen times have I produced spasm of the womb from giving a little too much ergot during the menstrual activity. Considering the cause of spasm in general, which is either irritation from dilated blood vessels in motor centers or peripheral irritation of sensory terminals from the same cause, reflected through motor centers to the muscles involved, ergot would appear to be indicated rather than contra-indicated in spasm. I know that in many spasmodic or convulsion conditions ergot is beautifully effectual in relieving. Asthma has yielded in a few minutes to ergot, even when the attack has been extreme and prolonged; and many cases of uremic convulsions have been as promptly relieved by ergot. When I speak of using ergot, I always mean hypodermically, as I have no confidence in its desired action when administered by the mouth, which is often, also, offensive to the stomach. The two methods are not to be compared as to their desirable results.

PUERPERAL ECLAMPSIA.

Obstetrics is out of my sphere of practice, and I have had no opportunity to demonstrate the applicability of ergot to puerperal eclampsia, but, considering its essentially-like causation to that of uremic convulsions from toxins, which disturb the circulation in nerve centers as well as the probable inefficient glandular activity in eliminating those poisons, I do not hesitate to commend its trial in that affection, believing that happy results will be obtained. Doubtless many will hestitate to give ergot to the pregnant woman, but I have frequently so used it without ill results, and I have had the assurance of a celebrated gynecologist that he would use it in pregnancy if indicated. In the convulsions occurring before or during labor, I would use it cautiously, but after the womb is emptied, I would use it freely and would expect to see brilliant results.

HYSTERO-EPILEPSY, CHOREA, ETC.

Had I time, I would relate a striking case of hystero-epilepsy of considerable duration who, during the convulsions, required half a dozen men to hold him in bed and who was practically cured from the first hypodermic, no further convulsions occurring. In the same way, I have relieved ordinary hysterical convulsions in a few minutes. The cataleptic hysteric is a typical case for the administration of ergot. With ergot you will cure the acute choreic promptly instead of waiting weeks and months, perhaps vainly, for the action of tonics and nerve sedatives. The old chronic choreic as well as the chronic sufferer from paralysis agitans you will not promptly cure, but you will promptly benefit and accomplish more with ergot than with any other drug. In infantile convulsions and paralyses and in the night terrors of children I earnestly commend to you the use of ergot, but I also commend the careful inspection of prepuce and clitoris and the correcting of their abnormalities. Indeed, in all convulsive and nervous conditions not clearly related to toxic influence examine carefully the sexual and pelvic organs for primary causative irritation, after which consider the digestive tract.

In epilepsy you will have all the advantages from the use of ergot that you have had from the bromids, without the latter's tremendous disadvantages.

BULBAR PARALYSIS, PARESIS, ETC.

As illustrative of the successful use of ergot in a condition regarded as incurable, I will relate another case.

Ten years ago a man came to me to have the galvano-eautery used on the back of his neck. He said, in effect, that he had consulted neurologists in Buffalo and New York, who had agreed that he had a fatal disorder, bulbar paralysis. The New York specialist exhibited great interest in his case as a rarity, and assured him that his was a beautiful case, but that all such cases progressed to fatality, though, possibly, cauterization might give him some temporary relief or extenuation of life. I saw that the poor fellow was frightened almost to death and, while he was not there to consult me, humanity led me to attempt to modify the influence of the unfavorable prognoses and to say that I thought that some other treatment would be much more beneficial than what he came for. He was in a state of mind to grasp at straws and requested me to treat him. I do not answer for the diagnoses, but they were made by those whom I regarded as more competent than myself. My own judgment was rather that he was developing general paresis. However, I treated him thoroughly with ergot and galvanism and he had no other treatment except buckthorn as a laxative. He made a rapid recovery, and has been in good health since and active as a public speaker.

I have had well-established cases of general paresis so improved by ergot that I questioned the correctness of my diagnosis, and I believe that if paresis could be so treated in the early stage it might be cured.

ACUTE INFLAMMATIONS.

Another class of diseases should be considered in relation to ergot, the acute inflammatory. It is surely rational to assume that ergot is indicated here, for the central element is dilated blood vessels, and ergot does contract the dilated blood vessels. But, better than theory is demonstration, and I have repeatedly demonstrated its value in meningitis, pneumonia, peritonitis, appendicitis, metritis, tonsilitis, erysipelas, erythema and inflammation of veins and arteries. The nearer to the initiation of inflammatory states you apply ergot, the more beautiful will be the demonstration of its effective action. I have also used it largely in the zymotic diseases to control or modify local hyperemia, which give pain and discomfort. I know that it is possible to make even the very sick comfortable, and there is some satisfaction in being comfortably sick. The sequellæ of influenza, the most serious part of that disease, local passive

congestion in one or more vital organs from paresis of vaso-motor centers, are relieved by ergot, though often slowly, as the influenzic poison has a peculiarly persistent depressing action on the sympathetic ganglia, but persistent use of ergot will overcome this.

TYPHOID FEVER.

I will be very grateful if some of you gentlemen who frequently treat typhoid fever will use ergot from the beginning. I am sure that by it you will accomplish several desirable results; limiting the local inflammation that so often leads to hemorrhages and perforation, the fatal elements of the disease, securing better elimination of the septic contents of the bowel by stimulating its muscular coat, preventing the head symptoms by holding the circulation there in tone and, by its effect on the general circulation, relieving the work of the heart.

ANGINA PECTORIS AND OTHER HEART AFFECTIONS.

There is still another class of disorders in which ergot stands pre-eminent as a means of relief—I refer to all those conditions, whether in kidneys, liver, lungs, brain or digestive tract, which produce functional and sometimes, later, organic trouble in the heart. It appears to me that quite too much attention is given to the heart in many cases and not enough to the conditions that have produced and are producing the symptoms in the heart. In general, the heart symptoms themselves and the remote states of disturbed circulation which produce them will be more effectually corrected by ergot than by any other drug of the materia medica. To use a pertinent slang expression, "It makes me tired," as the practice makes the poor hearts of the subjects so treated, when I think of the prodding and spurring of that overwrought organ by all the heart tonics and heart stimulants the doctors can think of, or, in other cases, lowering its force by sedatives and depressants, when the real indication is to remove the conditions which are overworking it or the conditions which are irritating its motor center; in other words, securing as promptly as possible approximate equilibrium of the circulation, to which end ergot is the desideratum. To this end I declare ergot to be tenfold more valuable and efficient than all the heart tonics, heart stimulants and heart sedatives combined. Do not understand me as condemning these classes of medicaments. I am only condemning their improper use. A disorder associated with what I have been saying is angina pectoris, in which I have used ergot with the happiest results. I recently heard a paper on that subject by a prominent practitioner personally known to many of you. I was asked to take a part in the discussion, and commended ergot. The physician promptly replied that "of all drugs, that one was most contraindicated." I will only say that if in angina pectoris or any other affection you deem it undesirable to make the labor of the heart as easy as possible by removing barriers that it can not surmount and lifting loads that have fatigued it, or undesirable to calm excited nerve centers that have made its action tumultuous and straining, then do not give ergot, for it is surely then contraindicated.

PRELIMINARY TO OPERATION.

I will detain you with but one more suggestion as to the therapy of ergot, which leads me into a field whose workers are not much given to the use of medicaments. And yet I am convinced that this one drug will be found by the surgeon who fairly tests it in his practice as valuable and necessary for the purposes which I shall point out as anesthetics or antiseptics for their especial purposes, and more valuable to him than any other drug outside of those classes.

The present era of surgery is the most brilliant of all history, so brilliant that the mind that contemplates it is dazzled as the eyes are dazzled by looking at the sun. The foundation on which this grand superstructure has been builded is antisepsis, the destruction of those microscopic organisms whose presence in wounds produces inflammation, which has always been the Waterloo of surgery. It is no disparagement to modern surgery to recall that before the day of antiseptics the surgeon was not always defeated; that, indeed, his victories were counted by the thousands and tens of thousands; and why? We surely can not assume that the bacterium did not then exist, any more than we can assume that the mass of mankind who do not develop tuberculosis are never exposed to its bacterium. There was in those successful cases a condition that prevented the fatal activity of the bacteria. I believe that the explanation is to be found in the state of the circulation. Inflammation can only follow congestion, and congestion can only occur when the walls of the blood vessels in the injured or wounded part have not sufficient tone. Where there is not that sufficient tone ergot will develop it, and this is the function and province of ergot in surgery. In all cases where there is time and opportunity to prepare a subject for operation by a preliminary course of ergot it should be done as carefully and conscientiously as you would secure the most perfect antisepsis during and following the operation. When the subject can not be so prepared in advance, the administration of ergot should be made hypodermically before and during anesthesia and operation and afterward until the healing is complete. You will find that the subject who has had a proper preliminary preparation by ergot for operation will have little or none of those distressing and often seriously objectionable accompaniments and sequellæ of anesthesia, nausea, retching, vomiting and delirium; and fluid nutriment may be safely given, as a rule, within a couple of hours after operation and at intervals thereafter.

SHOCK.

That great immediate dread of the surgeon, shock, will also be wholly prevented or greatly modified; and in those cases in which shock has preceded the surgeon's relation, ergot will quickly prepare the subject for prompt and safe operation, when delay or the imposing of operative shock on the previously shocked nervous centers would be fatal. Pain, for which the surgeon is accustomed to administer morphia, a drug that congests and disturbs every vital function, will be prevented by keeping the circulation under the influence of ergot, for it is congestion which determines the pain. Thus morphia may be avoided, which is always desirable; but if it must be administered, combine it with plenty of ergot to prevent its undesirable effects. After operation the thing desired is repair, and the sooner it is accomplished the better for the surgeon's reputation and the patient's satisfaction and future usefulness.

When you read in the evening paper: "Mr. John Jones was operated on to-day at the Blank Hospital by the famous Dr. Blank. The operation was successful." And, a few days later, you discover Mr. John Jones' name in the obituary column, it means that there is something more to be desired than surgical skill and the bacterial destroyer. That desirable thing is a proper activity of the circulation in general and, in particular, in the region of the operation. That proper activity is only

secured by a certain caliber of the vessels which carry to and from that region the nutritive fluid, and I feel that the most important message which I bear to you tonight is that ergot will, more surely and effectually than any other means, determine that proper caliber; whether for repair of a wound after operation or for aborting or minimizing an acute inflammation, or for raising the blockade that has wearied or exhausted the heart, or for relieving a coma or paralysis or convulsion, or for promoting the absorption of exudates, or for restoring normal function in an organ, or for calming an excited nerve center, or for relieving pain, or for simply restoring that general equilibrium of the circulation which warms the cold hands and feet, cools the hot brain and brings to an unhappy mortal, calm, comfort and peace.

Now, as a stranger to you, and without the weight of that bubble, reputation, to impress my words on you, I will confess that I do not expect you to accept now, nor until you have made the demonstrations for yourselves, all the claims I have made for ergot. I know that much of what I have said is novel to the mass of the medical profession and, in the developing of the application of ergot to disease, I have often scarcely credited my own senses, so astonishing was its action. I know, too, that a widespread prejudice exists against ergot; that it is regarded by many as a criminal among drugs. Patients of mine traveling abroad have been unable to purchase it in some countries of Europe, being told that it was a rank poison, and many physicians in this country have expressed the same view. At the sacrifice of conventional form in medical literature, I have endeavored to impress on you more strikingly the facts I had to present, the theories I wished to express. If I have so far succeeded in awakening your interest in ergot as to lead you to a wide and widening practical application of this efficient and remarkable drug, my mission tonight will have been attained. How you may regard me, concerns few beside ourselves. How you may regard ergot, vastly concerns thousands whose lives and futures will be placed in your hands in the years to come. You may have been impressed that I have a kaleidoscopic view of ergot or that it is to me like a musical instrument, a harp of a thousand strings, on which I play many tunes. If you will analyze all that I have said, you will find but one chord, one string, that makes, like Paganini's, many tones; which, unlike Paganini's, are harsh and inharmonious, unhealthful. All that is novel in the broad therapeutic application of ergot is the recognition of the varied, unhealthful tones of that one chord in all the diseases I have mentioned. That chord is *abnormally dilated blood vessels*. Ergot is the master hand whose magical touch vibrates them to harmony and health.

THE MODE OF PREPARATION AND OF USE.

Since the publication of the Chautauqua paper I have had so many inquiries as to the preparation I use, dose, method of administering, etc., that I will anticipate such inquiries in relation to this paper. I have experimented with a great many solutions which I have made, the object of which was to find that antiseptic which would best preserve a watery solution from bacterial development, toward which there is a great tendency in ergot, and to avoid the pain in introducing it hypodermically, and to prevent local congestion or inflammation at the region of application. I discarded three classes of antiseptics, the mercurial, from the great irritation; the iodin group, because of their tendency to set free the iodin, and the carbolic acid group, because of the tendency to produce a turbid state, a suspension of a fine precipitate which filtration would not correct. I have also experimented with every preparation of ergot to which my attention has been called, only to discard all except the preparation of aseptic ergot, which is put up in tiny bottles, hermetically sealed, each containing one ordinary dose. This solution is the most satisfactory of all the preparations I have experimented with except my own solution, and I do not hesitate to recommend it. However, I prefer this solution:

> Squibbs' extract of ergot 1 drachm, dissolved in solution formalin (1/3000) one ounce. Mix.

The distilled water should be boiled to sterilize, and, after cooling, the formalin added before the ergot is dissolved. The solution should then be filtered. You should not allow yourself to get out of this solution, for, curiously, a solution that has been made a few days is more satisfactory to the patient, giving less hurt, than one freshly made. Until the last two years I purchased the ounce or 25 gram jars of Squibbs' extract, but I much prefer, as being less troublesome and being always surely aseptic, the drachm packages wrapped in tinfoil, which my friend, Dr. E. H. Squibb, has been preparing for me. In making the solution great care should be taken to have everything used in the process thoroughly sterilized. It is better to keep in a cool place and protected what you do not carry with you. I regard the syringe used and the care of the needles as important. The best syringe is a glass one with asbestos plunger. As avoiding trouble in refilling, I prefer a syringe that holds a drachm or more. I always scour the needles, after each use, with sapolio, having filled the syringe with distilled water, which I throw through the needle slowly and continuously while drawing it from base to point between thumb and finger, which holds some powdered sapolio, then rinse well and dry with tissue paper outside and the inside as well by screwing the needle on a cone of the tissue paper, afterwards wrapping each needle in a bit of tissue paper, which sufficiently protects it.

A minimum effective dose, for an adult, of this solution, I would regard as 15 minims, but I seldom give less than an ordinary hypodermic syringeful, 25 or 30 minims, and often two such syringefuls. In extreme cases, as uremic convulsions, I have given four such syringefuls. One syringeful will generally relieve even a bad headache, but if not relieved in half an hour, repeat the dose.

It is always well to continue to use ergot, where there is a congestive tendency, for some time after symptoms have disappeared. The largest quantity of ergot that I have given in twenty-four hours is ten ordinary syringefuls.

As to the place of application, I prefer the deltoid of the left arm. It seems better to inject into muscle, but the space between the scapullæ is a good one to inject under the skin. Unless there is good tone in the blood vessels where it is injected, ergot will cause some congestion and sense of soreness until a few doses have improved the tone of the circulation, after which the patient will not mind the injections. Sometimes it would be a good precaution and never out of place to especially cleanse the skin where the needle is to be inserted.

I have never had an abscess purely from ergot, not a half dozen in all my experience, and those clearly explicable, as from an associated irritant. Always inject ergot slowly, keeping the finger on the stem of the

plunger and against the base of the syringe, to avoid suddenly throwing in too rapidly because of irregularities in the bore of the syringe or inequalities of pressure.

Finally, as to ill effects in general and, in particular, that dreadful sequence, ergotism, I am reminded of a celebrated chapter, whose title and text I will quote:

"On Snakes in Ireland.
There are no snakes in Ireland."

I have had a large experience with ergot, and I have never seen a suggestion of ergotism, nor any other effect that I could denominate ill. If you are looking for "snakes" in ergot, you must search elsewhere than in Squibbs' tinfoiled lozenges, and I think you will fail to find them lurking in the tiny bottles of aseptic ergot.

With a proper solution and the syringe and needle sterile, use ergot freely until you have secured the desired effects, and do not lie awake at night in dread of "snakes" in ergot.

DISCUSSION.

Dr. F. H. Wiggin, New York, said he could corroborate many of the statements made in the paper. His first trial of ergot was in a case of very dangerous intestinal paresis following a difficult laparotomy. The patient received ten syringefuls in 24 hours and was greatly benefited thereby. Administration continued on signs of relapse and recovery was uneventful thereafter. The drug was also useful in controlling nausea following anesthetic. The pain of acute articular rheumatism and also the morphin habit were controlled by it.

Dr. O. W. S. Toms, Nyack, N. Y., described a severe case of acute pulmonary edema which had yielded most satisfactorily to two syringefuls of Squibb's ergot solution. The attack had been brought on by disturbed compensation of the heart. Another interesting case reported in detail was one of severe purpura associated with rheumatoid and neuralgic pains and hemorrhages from the bowel. There were recurrences of eruption each time the patient came out of the influence of morphin. Finally ergot was given hypodermically with remarkably good results. Two injections were given daily for a few days. After each administration the rash became dark and was quite pale by the next day.

Dr. Charles Phelps, New York, had found ergot very useful in arteriosclerosis, and believed it should prove of value in cases of cerebral contusion.

Dr. Willis E. Ford, Utica, N. Y., said that even though some of the claims made in the paper seemed hard to believe they should be accepted with confidence, for he could personally vouch for Dr. Livingston's experience and diagnostic ability in the field of neurology. He had found ergot useful in subinvolution and chronic metritis responsible for failure of lactation. It was difficult to believe that this drug could take the place of well-known heart tonics and stimulants, but if it were so ergot would certainly assume a new prominence.

Dr. Alexander Lambert, New York, said he had recently made an extensive trial of ergot. The first case was a desperate one of angina pectoris, in which the usual remedies had utterly failed. In 10 minutes after the first injection of ergot he was completely relieved, and this experience was duplicated in several subsequent attacks. In a case of opium poisoning the use of ergot had permanently restored the patient to consciousness. A most interesting experience had been with 10 cases of alcoholic wet brain in Bellevue Hospital. Formerly under the most approved treatment this class of cases had yielded a mortality of 95 per cent., but in the present series, treated by ergot in doses of 15 minims every 2 hours, 7 cases out of 10 recovered. Ergot was also of greatest value in relieving the depression and tremor of ordinary acute alcoholisms. He had used ergot also in several cases of severe alcoholic pneumonia and in pulmonary congestion and edema with the most satisfactory results. One case of surgical shock was reported in which ergot had controlled severe shock promptly and had enabled an urgent operation to be done successfully.

Dr. Edward W. Lee, New York, said that for many years he had used ergot with apparent benefit in chronic hypertrophy of prostate and in acute inflammation of this gland.

Dr. Livingston, in closing the discussion, said he had used ergot in cases of concussion of brain with decided benefit.

Special Article.

THE TYPHOID EPIDEMIC AT ITHACA.*

(By Our Special Commissioner.)

I.

The city of Ithaca is most attractively situated in central New York at the upper end of Lake Cayuga, about one thousand feet above the sea level. The location and surroundings suggest unusual healthfulness, and, with a single exception, to be noted presently, there has been, up to the present year, no markedly excessive prevalence of disease. According to the United States Census for 1900 the death rate for that year was only 16.3. The town is reported as having 194 manufacturing establishments with an aggregate capital of $3,000,000, but it is chiefly celebrated for being the seat of Cornell University, and is pre-eminently a college community. During the college year the student population constitutes nearly one-fifth of the total number of inhabitants.[1]

In the matter of general cleanliness and attention to garbage disposal and other sanitary details, Ithaca does not impress one as being any more lax than scores of similar communities. Indeed, it is probably considerably superior to most non-college towns of its size and surroundings, and so far as appears, there has been only a single indication that Ithaca was not an unusually healthful community.

PREVALENCE OF TYPHOID FEVER IN FORMER YEARS.

For many years prior to the present outbreak typhoid fever, or a disease closely resembling it, so far from being an uncommon disease in Ithaca, has been rarely absent. A low type of fever, deemed by some so peculiar to the town that it has been honored by the designation of "Ithaca fever" (save the mark!) has occurred with varying severity for years. In the year preceding the present epidemic, cases of "Ithaca fever" and kindred illnesses appear to have been especially numerous. According to the official record of the university infirmary, "eighteen cases of typhoid and enteric fever, some of them very severe," were cared for in that institution during the year 1901-02. I have found that not infrequent mention of cases of typhoid fever occur in the files of a local newspaper during the months of January and February, 1902, and it is well known among the Ithaca physicians and some of the townspeople that a considerable number of cases of "fever" occurred at that time. In

* It is to be understood that the matter appearing last week was merely a preliminary statement based on information then obtainable.

1. Population, U. S. Census, 1900, 13,136. The number of students recorded in the University Register at the beginning of the year 1902-03 was 2,686, but 165 of these were residents of Ithaca and are probably included in the census enumeration.

the opinion of some who have investigated the matter, the number of such cases should be placed as high as one hundred. In one of the earliest notices of the present epidemic[2] a comparison was drawn between "the epidemic of this year and last."

BEGINNING OF PRESENT EPIDEMIC.

As far as the facts can be obtained regarding the time of onset of the present outbreak, it appears that about fourteen cases of a low fever, possibly typhoid, occurred between Nov. 17, 1902, and Jan. 15, 1903. Then, on January 1, some five or six cases of fever developed, and during the following week several cases each day were reported. After January 25 the number of cases reported daily seems to have increased very materially, and the existence of a serious epidemic began to be admitted, although most unwillingly. Some general uneasiness, however, seems to have been felt as early as January 22. On that date one of the Ithaca papers[3] contained the following editorial note:

Boil the drinking water. Reports from physicians show that there are several cases of typhoid fever in the city. Impure drinking water is one of the most fruitful sources of typhoid infection. If you would take no risk, carefully prepare every drop of water you drink.

On the day preceding this statement, the same paper contained a note on typhoid fever in Philadelphia with the following somewhat pragmatical comment, which, in the light of subsequent events, reads rather curiously:

The cause of the epidemic in Philadelphia is attributed to a poor water supply, and Ithacans who visit the Pennsylvania metropolis should be careful about what they drink. It is a safe rule never to drink water at any time unless perfectly sure of its purity.

By February 2 the gravity of the situation in Ithaca had become clearly manifest. On that day the following statement was made in the local press:

The epidemic of typhoid fever is spreading with terrible rapidity throughout the city. The physicians are over-worked, the hospitals are over-crowded, nurses are lacking to care for the sick, and two deaths have been caused by the disease, one Saturday and one to-day.

DIMENSIONS OF EPIDEMIC, NUMBER OF CASES AND DEATHS.

It is unfortunately impossible to obtain precise information regarding the time of beginning of the outbreak, the sequence of the cases and the dimensions of the whole epidemic. The records of the local health board are in a confessedly fragmentary and imperfect condition, and the actual number of cases occurring in Ithaca during the early months of 1903 will probably never be known. I am informed by Dr. G. H. Soper, the representative of the New York State Board of Health, that he had secured a record of 770 cases that had developed prior to March 12. This, however, is generally believed by Dr. Soper and others, who have firsthand knowledge of the epidemic, to fall somewhat below the truth. Just how far below is a matter for conjecture. Some observers would place the number of cases at over one thousand, and lay great stress on the existence of a large number of ambulant cases, but it must be remembered that a number of such cases occur during every typhoid epidemic, and there seems to be nothing to indicate that the Ithaca infection has given rise to a disproportionately large number of cases escaping the notice of physicians.

Among the students in Cornell University the epidemic has found many victims. The university authorities had, on March 12, a record of 119 cases with 12 deaths, that had occurred among the students remaining in Ithaca; and of 46 cases and 10 deaths reported from among those students who had gone from Ithaca to their respective homes. It is estimated that at least one-third of the total number of students left Ithaca after the outbreak of the fever, so that the 46 cases reported to the university authorities constitute only a fraction of the number in whom the disease developed outside of the city. The writer has obtained, in fact, the names of eighteen students not on the university lists who are reported as ill at their homes from typhoid fever contracted in Ithaca. From the files of local newspapers have also been obtained the names of seventeen persons who are believed on strong grounds to have contracted typhoid fever in Ithaca, but who developed the disease outside the town, for the most part in neighboring villages. One case, however, presumably contracted in Ithaca, has appeared as far away as Wheatland, South Dakota. From the best information obtainable, therefore, the number of cases that can fairly be attributed to infection in Ithaca, between January 1 and March 12 is as follows:

	Students.	Citizens.	Total.
Cases in Ithaca	119	651	770
Cases outside of Ithaca	64	17	81
Totals	183	668	851

The record of deaths, although doubtless incomplete, probably presents a narrower margin of error than the cases.

TABLE I.

DEATHS FROM TYPHOID FEVER ATTRIBUTABLE TO INFECTION IN ITHACA.[4]

Jan. 23.... 1	Feb. 14.... 1	Feb. 28... 3

SAME RECORD, BY WEEKS.

Jan. 23 to Jan. 29	1
Jan. 30 to Feb. 5	4
Feb. 6 to Feb. 12	6
Feb. 13 to Feb. 19	11
Feb. 20 to Feb. 26	11
Feb. 26 to March 5	10
March 6 to March 12	5

For reasons already stated definite information can not be obtained regarding the sequence of cases in the whole population. The facts are at hand, however, concerning the dates at which some 97 Cornell students were admitted to the university infirmary and its annexes, and these afford probably as reliable information as can be secured regarding sequence.

2. Ithaca Daily News, Jan. 26, 1903.
3. Daily News, Jan. 22, 1903.
4. Including 12 students who contracted the disease in Ithaca, but died at their homes.

TABLE II.[5]

CASES OF TYPHOID FEVER OCCURRING AMONG CORNELL STUDENTS IN ITHACA, THE DATE OF INCEPTION OF WHICH IS APPROXIMATELY KNOWN.

Jan. 23.. 1		Feb. 4.. 5		Feb. 16.. 1		Feb. 28.. 1

In addition to this number, 22 students have been ill in lodgings or in the city hospitals, the date of the beginning of their cases being apparently unknown. So far as can be learned, the sequence of cases in the town followed closely the sequence of cases among the students, but owing to the laxity of report and record, already referred to, even the approximate dates of the beginning of the disease can not be ascertained.

There seems at first to have been much doubt as to whether the fever was really typhoid fever or the familiar "Ithaca fever." The latter disease, apparently, did not seem so formidable to many citizens.

Throughout the epidemic the situation has been singularly befogged by a tendency on the part of certain of the Ithaca physicians to deny the prevalence of "genuine" typhoid fever, and to ascribe the prevailing illness to "paracolon infection." The evidence on which this view is based appears to be that a negative result with the Widal reaction has been obtained in a considerable proportion of the cases that have been tested. There is no instance where any paracolon or paratyphoid organism has been isolated from any case of the disease. Even if it were conclusively proven that half, or even all, of the cases of "fever" in Ithaca were true "paracolon" infections, it is difficult to see why that fact should materially influence the general situation. It must still have been admitted that a disease of serious character which can not as yet be clinically differentiated from typhoid fever, and which, so far as is known, does not demand essentially different treatment, prevailed excessively in the town. Whatever the nature of the microorganism, the probable mode of infection and the sources of the infection remained the same, as did the necessity for taking vigorous measures for preventing its spread. There was not a single particular in which the practical handling of the outbreak could have been affected, even if convincing evidence had been secured that all the cases in Ithaca were paracolon cases. The insistence on a distinction, which, under the circumstances, could possess only an academic value and did not facilitate immediate and aggressive action was not a fortunate policy.

(To be continued.)

5. The several dates refer to the day of admission to the infirmary and can be taken as only an approximate indication of the day of inception of the disease.

Gail Borden, inventor of the system of condensing milk, died at San Francisco, Cal., November 26, from poisoning, "after eating a duck that had been kept in cold storage."

Suicides in American Cities.—If we may rely on the statistics quoted by the *New Orleans Times-Democrat*, there are some strange facts as to the relative rate of suicides in the different American cities. San Francisco has the largest ratio, 39.1 per 100,000 of population. Next comes Los Angeles, 29.8. Chicago is the third in order with a ratio of 24.0, followed by the neighboring city of Milwaukee, whose ratio is 22.2, and then New Orleans, 21.8, and Cincinnati following close with 21.2. New Haven is next with 20.9, and then comes the Borough of Manhattan with 20.0, though Greater New York, as a whole, is well down the list with a ratio of only 13.6. This is less than Rochester, Indianapolis, Philadelphia, Pittsburg, Baltimore, Boston, Detroit, Omaha and Louisville, besides all of those specifically enumerated above. As to the foreign cities, Paris leads the list with a ratio of 42, followed by Berlin, 36; Vienna, 28, and London, 23. There were more suicides in Saxony than in any other country, 31.1 per 100,000. In Denmark the ratio was 25.8, in Austria 21.2, in France 15.7, in the German empire 14.3, and Sweden, Norway, Belgium, Great Britain, Italy, the United States and Spain followed in the order given. Can any of our social philosophers explain why the San Francisco and Los Angeles rates are higher than Chicago? The "foreign element" in Chicago, Milwaukee and Cincinnati can not explain why their rates are so much higher than New York City, where there are also large foreign populations. Does New Haven, in fact, have a higher rate than all other New England cities? And why is the rate in Minneapolis almost double what it is in St. Paul? Will the *Times-Democrat* tell us where it got its figures?—*American Medicine.*

National Charters.—Those interested in securing a National charter for the American Medical Association will be interested in Senator Elkins' bill, which has received the approval of the district commissioners; to incorporate the National Hay Association of the District of Columbia:

Be it Enacted by the Senate and House of Representatives of America in Congress Assembled: That [then follows the names of the incorporators] their associates and successors are hereby created in the District of Columbia a body corporate and politic by the name "The National Hay Association," for the purpose of advancement of the commercial interests of those engaged in the handling of hay and straw, inculcating just and equitable principles in trade: acquiring, preserving and disseminating valuable business information; establishing and maintaining grades of hay and straw and securing their adoption in different markets of the country and facilitating business intercourse. Said association is authorized to have an official emblem and hold real and personal estate in the District of Columbia so far only as may be necessary to its lawful ends in amount not exceeding $5,000, to adopt a constitution and make by-laws, not inconsistent with law. Said association shall have its principal office within the United States as it may determine and may hold its annual meetings at such places as the said corporators may determine.

The following is the National charter of the American Historical Association, known as public No. 10, and reads as follows:

Be it enacted by the Senate and House of Representatives of the United States of America, in Congress Assembled: That [then follows the names of the incorporators] their associates and successors, are hereby created in the District of Columbia a body corporate and politic, by the name of the American Historical Association, for the promotion of historical studies, the collection and preservation of historical manuscripts, and for kindred purposes in the interest of American history and of history in America. Said association is authorized to hold real and personal estate in the District of Columbia so far only as may be necessary to its lawful ends to an amount not exceeding $5,000, to adopt a constitution, and to make by-laws not inconsistent with law. Said association shall have its principal office in the District of Columbia, and may hold its annual meetings in such places as the said incorporators shall determine. Said association shall report annually to the secretary of the Smithsonian Institution concerning its proceedings and the condition of historical study in America. Said secretary shall communicate to Congress the whole of such reports or such portion thereof as he shall see fit. The regents of the Smithsonian Institution are authorized to permit said association to deposit its collections, manuscripts, books, pamphlets, and other material for history in the Smithsonian Institution or in the National Museum, at their discretion, on such conditions and under such rules as they shall prescribe.

The general impression is that the Elkins bill will not become a law.

SATURDAY, MARCH 21, 1903.

TROPICAL MEDICINE.

The problems of tropical medicine are becoming of more importance each year with both the profession and the public. The world is filling up, population is spreading over the known habitable regions and the call is ever for more territory for civilized man to conquer. Even on this continent the land hunger is no longer appeased except by encroaching on the semi-arid regions of the west or the sub-arctic territories to the north. The improved means of communication have brought all countries nearer together and the tropical regions of the world are thus made our immediate neighbors and common resorts for vacation excursions. Nearly every civilized country, too, has now its tropical dependencies or is seeking for such. Our own country is no exception, the problem comes home to us now and will be of still more importance as the years go by.

The two chief questions are, 1, the habitability of the tropics by the white race, and 2, the introduction of parasitic tropical disorders into the temperate regions by means of the increasing intercourse and facilities of communication. As regards the first of these, it was maintained in 1898 by such experts as Sambon and Manson that the acclimatization of the white races in the warmer regions of the earth was a practicable possibility. There was, they held, no adequate reason why white men might not live comfortable and useful lives in tropical countries; and the special disorders that have been considered as preventing this were themselves almost universally parasitic and preventable. Any special racial immunity to them was really an acquired one, and there was no reason why, with our increasing knowledge of these disorders, they might not be met and overcome by proper sanitary measures, and why the individual might not also acquire a like immunity. Race deterioration, according to Sambon, is a far more serious question in the crowded urban population of our great centers of civilization than in the tropics, and we have abundant instances of the ability of right-living whites to exist and prosper by their labor under a tropical sun.

Sambon could hardly have fully foreseen how completely his anticipations have been realized, in the phenomenal increase of our knowledge of tropical diseases and of the means to prevent them since 1898. Within that five years or less we have learned in a great measure how to meet and conquer malaria, the chief of the captains of death in tropical regions; yellow fever, which in its more limited scope was even a worse scourge than malaria, has been shown to be preventable; the causes of tropical dysentery and tropical anemia have been elucidated and the acquisition of the successful methods of their prophylaxis and treatment seems only a matter of time. The success of sanitation in Havana, formerly a typical tropical city in its unhealthfulness and now with a mortality rate below that of many northern cities, is an object lesson of what may be done elsewhere, and almost in itself an answer to our first question, "are the tropics habitable by civilized man?"

The second question is one that directly affects us at our homes. With the yearly increasing intercourse with all parts of the globe, it is becoming impossible to absolutely shut out disease from other regions, even with the strictest quarantine. More and more of our people are residing temporarily or traveling in tropical countries and returning, bringing with them the diseases they may have contracted. Moreover, not all the disorders that we call tropical are strictly such. We find that Shiga's bacillus is the cause of much of our prevailing or locally epidemic bowel disorders in our own climate; uncinariasis, with its attendant anemia, is prevalent in our southern states, and malaria even in its pernicious estivo-autumnal type, may occur almost anywhere within our own borders. American physicians will from this time on have more experience with these disorders and greater need of knowledge for their recognition altogether apart from the possibility of their having to deal with them in actual tropical practice. Admitting that the data already obtained will make them comparatively manageable, there is the constant possibility of new problems arising. We can not bring at once all parts of the world under good sanitary conditions, and there will always be reckless individuals neglectful of hygiene, therefore the worst possibilities are always to be considered. Eternal vigilance is the price of public health as well as of our liberties, and we will do well to consider this fact, even as regards the disorders (so-called) of the tropics in our temperate climate.

With all these facts the importance of the study of these disorders is obvious. Whether they should be kept apart from diseases generally met or be reserved as a subject for special study is a question that might have been raised, but one that to a certain extent has been already answered in England where schools of tropical medicine have been in successful existence for some years. In this country little has been done, so far as treating the subject as a specialty is concerned, though we owe some of the best conducted and most fruitful investigations to our own countrymen. In one or two medical schools chairs of tropical medicine have been arranged for and others will probably follow the example. The subject is one that could appropriately occupy the attention of the American Medical Association at the coming meeting, occurring as it does in the subtropical section of the United States. Whether a special section

on tropical medicine should be constituted or whether the subject should be assigned to a subsection of one of those already organized is a matter for discussion and future settlement. For several reasons we believe that it would be unwise to create a new section, but that it should be made a subsection of that on hygiene and sanitary science. Tropical medicine, however, can not well be overlooked in any future program of the Association.

THE IMPROVEMENT OF THE MEDICAL AND SCIENTIFIC WORK IN OUR HOSPITALS FOR THE INSANE.

There seems to be a general desire among those interested directly in the medical work in the hospitals for insane to raise the standard of that work, to do something to prevent the physicians from falling into mechanical routine, which is the bane of institutional life as ordinarily lived. For some time there has been apparent a general effort to introduce into state hospitals for the insane systematic pathologic work. Pathologic laboratories have been equipped and special pathologists appointed to make postmortem examinations and microscopic and other studies of the accumulating material.

This is certainly a gratifying step in advance. The introduction of any form of scientific activity into these institutions can not but produce a stimulating effect on the medical staffs in general. But it is quite evident that the renaissance of the medical and scientific work of the hospitals for insane can not be accomplished by this movement alone. Indeed, mutterings are heard to the effect that purely pathologic work is not yielding all that was hoped from it; and the reason assigned for this disappointment is that the clinical work as generally done is wholly inadequate to furnish any satisfactory foundation for truly valuable pathologic studies. What is the use of making postmortems and cutting sections of nervous tissue so long as there are no systematic, reliable clinical observations with which the results of pathologic inquiry may be correlated? The reasons usually given for the shortcomings of the clinical work in its various aspects are that the medical officers of the hospitals lack proper training in neurologic and psychiatric methods and that their duties are so varied and onerous that time and energy do not suffice for anything more than the veriest routine. In the present organization of the staffs of the hospitals for the insane there is placed at the head of the whole a superintendent who, though a medical man, is held strictly responsible for every detail in the management. His prime object soon becomes to so conduct his institution that there is a reasonable freedom from gross scandal. Even with the very best of intentions he can not personally direct and train his assistants. These are left to their own devices and assigned to fixed, independent services without time or equipment to make real, systematic, unprejudiced studies of the cases placed under their care.

Evidently there is need for a reorganization of the medical staffs. More physicians must be employed, provisions must be made for their special training, and the medical services must be placed under competent heads with regularly subordinated assistants. Much of the work now done by hospital physicians is not of so strictly medical a character but that it can be done just as well by intelligent persons without medical training. Reforms along these lines might help to bring into the institutions something of that scientific spirit which is needed to overcome the benumbing influences of institutionalism and the tendency routine has to arrest intellectual development. We believe that these suggestions find a sympathetic ear in the conscientious hospital physician and in the public-spirited hospital trustee. In order to secure for the physicians special training in neurology and psychiatry, a training that the medical schools can not furnish at the present time, the most that can be expected being a general preparation for it by thorough schooling in the fundamentals of medicine, each state should organize special institutes manned by specially qualified teachers and thoroughly equipped for scientific clinical and laboratory work. In each of the larger, older states there are now two, three, and even more large hospitals for the insane. At present there is a growing tendency to centralize the administrative management of the state institutions, and the next step in the evolution of the state care for insane should be in the direction of centralization of the medical and scientific work in the manner outlined by the establishment of special psychopathic hospitals and institutes for the proper training of the physicians for all the hospitals in the state. The United States Army maintains an Army Medical School at Washington where the medical officers are given special training and to which they are detailed from time to time for instruction by special courses.

It is something on this plan that we have in mind for the men in the service of the state hospitals for insane. There is no reason except ancient custom why the assistants in the state hospitals should remain so fixedly attached to one institution as is the vogue now. It would seem practicable to place the entire personnel of the various medical staffs of the hospitals of a state under a central management that could distribute the physicians among the different institutions according as the good of the service and the special requirements sure to arise from time to time would indicate. The introduction of this principle would give to the hospital services a feature of elasticity that probably would prove beneficial alike to the hospitals and to the individual physicians. Then again, as men with special aptitudes were discovered and developed, their work could be encouraged by leaves of absence from regular duty, but with pay, for the purpose of special study at suitable places at home or abroad. Certainly the state could do much to raise the standard of the medical work in its hospitals for insane by careful organization of the medical services as a whole with a central institute at the head and by reorganization of the services in the single

hospitals along lines that tend to lift up the more purely clinical side as well as the pathologic. Conditions would then be established that would favor directly the growth of scientific work in the hospitals.

THE DEADLY HEADACHE POWDER.

Powders containing acetanilid, sold indiscriminately by the drug stores and used universally, possess dangers other than those due to their depressing effect on the heart, which in several instances has led to sudden collapse and even death. Acetanilid, and other substances of similar nature, have a marked hemolytic effect which is of great importance when this sort of medication is long continued. Stengel and White[1] have published a most instructive case-report, illustrating the very serious results that may follow drug taking of this kind. A young woman who had been suffering for four years from infradental neuralgia, developed severe symptoms that seemed of cardiac origin. She became extremely cyanosed; her lips, fingernails and toenails were dark blue or almost black. The heart's action was rapid and very weak, but in spite of all the cyanosis there was no dyspnea or edema, suggesting that cardiac incompetence was not the fundamental difficulty. Examination of the blood showed at one time but 2,092,300 erythrocytes, and 35 per cent. hemoglobin. There were 71,400 nucleated cells, of which no less than 32,323 were nucleated red corpuscles. Of course, all sorts of abnormal forms of erythrocytes accompanied this picture. Hemoglobin and hematin were present in the urine. For some time it was impossible to prove the origin of this severe anemia in drug taking, for not only did the patient deny the use of remedies, but her brother, who was a physician, was certain that the cyanosis was not due to a drug. At last, however, a box of capsules containing the familiar "headache and neuralgia" compound, acetanilid, caffein and bicarbonate of soda, was received by the patient, and eventually she confessed that for four or five years she had taken such compounds.

The secret way in which the headache powders had been taken, deluding even the patient's physician-brother, is very interesting, indicating that the victim of such a habit is not far removed from the morphin fiend. It suggests the possibility of similar cases existing in larger numbers than we appreciate, for in this case it is certain that the origin would not have been detected but for the careful blood examination and the deductions from its results. The changes in the blood were so characteristic of the action of a hemolytic agent, and so resembled those seen in the few accurately reported cases of poisoning by anilin derivatives, that the denials of both the patient and her brother were unable to draw the observers from the right track.

The effects of acetanilid, phenacetin, nitrobenzol and other poisons of the same nature are well known. Among the symptoms described are cyanosis, profound depression or collapse and unconsciousness; but, as a rule, dyspnea and subjective symptoms have been slight or wanting. There have been few chronic cases, similar to that of Stengel and White, reported as yet, but we suspect that they are not uncommon. In those so far studied the characteristic changes have been in the blood, including the presence of all sorts of altered red corpuscles, with great numbers of nucleated erythrocytes. In one case the proportion of the nucleated forms was as high as one to fifty-six of the non-nucleated.

1. Univ. of Penn. Medical Bulletin, 1903, xv, 462.

THE BUSY PRACTITIONER AND HIS OPPORTUNITIES.

We called attention some months ago[1] to the emptiness of the excuse given by a class of busy practitioners for their failure to interest themselves in what concerns the general good of the medical profession, such as society work, medical legislation and the like. They are, forsooth, too busy with their practice. For such men, as well as for the busy physician who faithfully tries to fulfill his duties to the profession and feels all the responsibilities of his professional work, a reference to some things that have been accomplished for clinical medicine by physicians in active practice may prove an inspiration. The "busy" man is apt to think that he should be exempt from the obligation of trying to extend the bounds of medical knowledge. His occupation, he may claim, is a practical application of the discoveries of others. Active practice absorbs so much energy and time as to leave none for anything beyond his patients and their immediate needs, and certainly no opportunity for original work. It used to be the excuse of the medical college professor that he had to devote so much time to teaching and practice that he could not be expected to do any investigating. Now it is recognized that only he can teach well who is himself doing original work.

Only the physician who so carefully examines his cases that he sometimes makes observations not to be found in the text-books, is doing his patients justice and keeping himself up to date. It is the men who thus impress their personality on medicine that receive the highest rewards of the profession, the confidence of their fellow practitioners—and frequent calls in consultation. Most of the great advances in medicine have come, not from ambitious theorists, but from the carefully recorded observations of the general practitioner.

The great principle of the conservation of energy was discovered by Robert Meyer while ship surgeon on a vessel in the Dutch East Indies. He observed during the practice of venesection that the venous blood drawn in the tropics was much redder than that he had seen in colder climates. He argued that this was due to the fact that less oxidation took place in the blood in tropical countries, because less work was demanded of it in keeping up the heat of the body. The surrounding air accomplished the purpose of heat production and so saved oxydizing processes in the blood. From this simple observation to the magnificent generalization of the con-

1. The Journal A. M. A., July 12, 1902, p. 84.

servation of energy seems a far cry, yet the basic principle of modern physics lies in the simple problem whose solution the young German physician grasped so clearly. Morgagni, whom Virchow greeted as the Father of Modern Pathology, was first of all a clinical observer, a careful student of the cases that came under his observation. His pathologic studies were always directed to the better understanding of his clinical cases, and that is what makes his great work of such practical value. Auenbrugger, the discoverer of percussion in the investigation of thoracic disease, was a simple practitioner of medicine all his life. While Auenbrugger was doing his great work in Austria Jenner was preparing for his in England. Jenner was just a country practitioner, but, in spite of all the *laissez aller* that term is supposed to imply, he was one of the keenest of observers. When he told the famous John Hunter of the popular belief in Gloucestershire that cowpox protected against smallpox, and that the subject seemed worth thinking about, Hunter blurted out, "Don't think, investigate." Laennec, his illustrious contemporary, the discoverer of auscultation, the greatest physician of the nineteenth century and one of the four or five greatest geniuses in the history of medicine, was just a medical practitioner with a hospital service. He took for the motto of his immortal work on auscultation the Greek maxim, "The most important part of an art is to know how to see things." Bright and Graves and Addison were busy physicians in the best sense of the term, yet were faithful observers who paid proper interest on the medical knowledge lent them, by handing it on notably increased in value to their successors. And there is yet, and ever will be, a place in the footsteps of such men for the earnest busy practitioners of this and every generation.

A TRAVELING POST-GRADUATE SCHOOL.

The German newspapers have recently announced the preliminary preparations for a migrating post-graduate school under the special auspices of the German government, which shall go from town to town away from the medical centers, carrying with it a museum and sufficient material to be of advantage for instruction and to include among its lecturers some of the leading lights in medicine and surgery in Germany. The idea of this seems to be the better education of the local physicians, who for various obvious reasons can not take a post-graduate course at the university. The mountain will go to Mahomet in this case. The project has the support of the emperor and is to perpetuate the name of the Empress Frederick and to be largely supported by government aid. As we understand it, the instruction is to be gratuitous for such physicians as attend. There is much that seems admirable in this plan, and it is to be hoped that it will develop into all that its well-wishers can desire. The German physicians will have the university brought to their very doors. It is, in fact, a special adaptation of the university extension idea applied to medicine and medical instruction; a proposition that can be carried out in this country by the profession itself when a little better organized.

AN EXTENSIVE BUSINESS IN PROPRIETARY MEDICINES.

The extent of the proprietary medicine trade is well illustrated by a recent statement in the *New York Commercial,* in its Indianapolis dispatches, that the latter city can, when running its manufactories at full capacity, supply annually over 21,000,000 ordinary barrels of remedies—of all kinds, we presume. It claimed in the dispatch that Indianapolis is the great medicine manufacturing city of the country and supplies not only the adjoining states, but more remote regions and even foreign countries. How much the popularity of patent medicines is due to the alcoholic contents of many of the nostrums it would be hard to say, but undoubtedly they go a long way in satisfying the appetite that for conventional, social or legal reasons can not be fully gratified otherwise. If the statements are true as regards this one city, what can we calculate as the drug output of the country as a whole? Making all due allowances for exaggeration the reality must be a sufficiently formidable one to give rise to some serious consideration.

THE MICHIGAN STUDENTS' PROTEST.

The proposed medical practice act for Michigan, which is intended to put the law there on the same plane as it is in other progressive states, is receiving opposition from the students of certain medical colleges of that state. These students object to passing an examination after obtaining a diploma, holding that the state, by the incorporation of these institutions, entered into an agreement with them by which they should have in their diploma the necessary qualifications for a license to practice without having to undergo an examination. Being graduates of Michigan colleges they think they ought to be favored above those who obtain their diplomas elsewhere. As far as we have been able to learn, they do not claim that their colleges are better than those in other states, or that they themselves are better educated. It certainly can not be possible that they are willing to let it be thought that they have a lack of confidence in themselves and in their medical scholarship or that they wish to cast any reflection on their alma mater by this plea for exemption from the state examination. And yet this is what one would naturally surmise. These students, it is said, are sending delegations to Lansing to lobby against the act. What influence they may have is more than can be foretold, but it is to be hoped that they may soon see the folly of this exhibition of selfishness, not to use a stronger term. These students seem to ignore the fact that this same fight has been made under similar conditions, and with like arguments, in other states, and without success. A funny condition would soon prevail if graduates of a medical college in a given state were to be exempt from the laws that applied to graduates from outside colleges. We hope the students of the Michigan medical colleges will see the unwisdom of their action and assist, rather than oppose, those who are fighting for the elevation of the standard of the profession which they are about to enter.

Medical News.

CALIFORNIA.

Jury Disagrees.—The jury to which was committed the case of Mrs. Julia Tickel, known as Mrs. "Dr." Jones of Fresno, charged with causing abortion, was unable to agree and was discharged.

Physician Wins.—In the case of Dr. Jacob H. Parseghian, Fresno, against H. Azhderian, for medical attendance furnished the son of the latter, the decision was in favor of the plaintiff for $400.

Indicted Optician Escapes.—A warrant was recently issued in Bakersfield for the arrest of C. Belmont, an optician, who, it was alleged, had practiced medicine without first registering his diploma. On attempting to serve the warrant, the constable discovered that the accused had gone to Los Angeles.

San Francisco Deaths.—During February 633 deaths were reported, which, after the deduction of 57 due to violence, leaves 576, equivalent to an annual death rate of 16.84 per 1,000. In February, 1902, the rate was 18.79 per 1,000. The principal causes of death were: Tuberculosis, 95; heart disease, 94; pneumonia, 61; Bright's disease, 42; cancer, 28; accident, 36; diphtheria, 14; suicide, 15; homicide, 6.

To Restrict Practice of State Employes.—The resolutions recently adopted by the San Joaquin Medical Society, directed against private practice by the physicians at the state hospitals, have been crystallized into a bill which has the following provisions:

> The medical superintendents and assistant physicians of the several state hospitals for insane persons must not engage in the private practice of medicine, but must devote their whole time to the performance of their duties, unless granted leave of absence by the board of directors. If any of such physicians shall engage in the private practice of medicine his office shall thereon become vacant, and the board of directors, or other appointing power, shall immediately appoint some qualified person, other than the officer whose office shall have become so vacant, to fill such vacancy.

COLORADO.

New County Hospital Staff.—The new staff of the Arapahoe County Hospital is made up as follows: Medicine, 9; surgery, 8; obstetrics, 3; gynecology, 3; eye and ear, 4; nose and throat, 1; nervous and mental disease, 3; orthopedics, 1; dermatology, 2, and pathology, 2.

Denver Health and Deaths.—The deaths during January numbered 235, equivalent to an annual death rate of 17.09 per 1,000. Tuberculosis caused 58 deaths; pneumonia, 30; inanition, 10, and violence, 9. Infectious and contagious diseases were reported as follows: Scarlet fever, 85; diphtheria, 69, and smallpox, 34.

State Vital Statistics.—The total deaths for January were 856, equivalent to an annual death-rate of 17.47 per 1,000. Typhoid fever caused 23 deaths, diphtheria 12 and scarlet fever 7. During the month, 379 cases of smallpox were reported, 78 of which were from Yuma County, 48 from Rio Blanco County, 47 from Otero County and 60 from Arapahoe County; 206 of scarlet fever, and 135 each of diphtheria and typhoid fever. Compared with December, 1902, January shows a decrease of 43 cases of diphtheria, an increase of 49 cases of scarlet fever and 153 cases of smallpox, and a decrease of 107 cases of typhoid fever.

DISTRICT OF COLUMBIA.

Health of the District.—The report of the health officer for the week ended February 28 shows the total number of deaths to have been 161, of which 91 were white and 70 colored; births, 116; number of cases of typhoid fever, 91; scarlet fever, 10; diphtheria, 6, and smallpox, 10.

Appropriation for Hospitals.—Congress has made an appropriation of $100,000 for the Providence Hospital, and $1.000 for the Garfield Memorial Hospital; $15,000 for the Washington Asylum Hospital, and $99,000 for the Government Hospital for the Insane, with $11,500 for a subway connecting the various buildings.

ILLINOIS.

Chicago.

Augustana Addition.—The long-planned addition to Augustana Hospital is to be erected this spring at a cost of $100,000. It will be fireproof, six stories high, and 110 by 130 feet.

Two Hospitals Fined.—Fines of $50 each were imposed on the Chicago Hospital and the Norwegian (Tabitha) Hospital, for violations of the city ordinance regarding elevators and elevator shafts.

Smallpox.—During the week seven new cases were reported. Only one patient, an adult, had been vaccinated, and he in infancy. No case of smallpox in a revaccinated person has been found in Chicago for years, says the department of health.

Deaths of the Week.—During the week ended March 14 631 deaths were reported, an increase of 6 per cent. over the mortality rate of the preceding week, and of nearly 10 per cent. over that of the corresponding week of 1902. Pneumonia led with 133 deaths, and consumption followed, with 60. Violence caused 20 deaths and suicide 17.

Vacuum Cleaning.—The department of health advocates the vacuum method of cleaning sick-rooms, saying that "consumption, pneumonia, influenza, scarlet fever and similar diseases are known to be spread by infected dust of the sick room, so the distinct and recognized purpose of the operation shall be to remove and not simply to stir up the ever-gathering dust.

Scarlet Fever Closes Lake Forest University.—Because of the continuation of the epidemic of scarlet fever at Lake Forest, the university will be closed for two weeks. The quarantine on the university grounds has prevented an extension of the disease among the students, but it is spreading in the town. No public meetings will be held. Most of the new cases have been in families where the disease already existed. No new case has occurred among the university students for about eight weeks.

IOWA.

Verdict for Defendants.—In the suit for $5,000 damages brought against Drs. Thomas J. and John R. Maxwell, Keokuk, by Mrs. Theresa Winkler, who alleged that the defendants removed a portion of her husband's brain during an autopsy and did not return it, the plaintiff was non-suited.

Resignations.—Dr. Lewis Schooler, Des Moines, for 19 years dean of Drake University medical department, has resigned, and Dr. A. Raymond Amos, now secretary, has been elected to succeed him. Dr. Schooler will retain the chair of surgery in the college.——Dr. Francis M. Powell, superintendent of the Iowa Institution for Feeble-Minded Children, at Glenwood for more than 20 years, has resigned on account of failing health.

Commendable Fraternity.—All but four of the physicians of Hardin County have joined in a petition with the object of aiding Dr. William E. Marsh of Eldora, who has become nearly blind. The petition asks the appointment of Dr. Marsh as the county physician employed each year to treat the poor of the county. In asking this appointment, the physicians agree to give their services whenever called on by the county, that is, to do Dr. Marsha's work for him. The salary is $800 a year. Four physicians declined to join in the petition and filed individual bids seeking the appointment as county physician for themselves.

Itinerants Must Leave State.—The State Board of Medical Examiners is announced to be about to undertake a crusade against the itinerant practitioners who infest the state.——R. D. Rea, recently fined at Emmetsburg for practicing medicine without an itinerant doctor's license, has combined with about 75 other specialists of his kind, retained an attorney and proposes to carry the case to the Supreme Court of Iowa, or if necessary to the United States Supreme Court.——G. H. Heath, a magnetic specialist who travels with his wife, a clairvoyant and another woman, a complexion specialist, was arrested at Poone, on the charge of being an itinerant practitioner without a license, and was bound over to await the action of the grand jury.

KANSAS.

Personal.—Dr. George C. Purdue and family, Wichita, are taking a trip to the south and Cuba.

Hospital Fire.—A fire at the Pittsburg City Hospital, February 21, damaged the building to the extent of about $1,000, but caused no casualties.

Patent Medicine Bill Dead.—This bill, which turns up at every session of the legislature, has been referred by the senate committee on hygiene and public health to its introducer, Senator Gabriel, for revision, and the senator declares that he will not reintroduce it.

To Prevent Marriage of Defectives.—The O'Donnell marriage bill passed the house, February 23, by little more than a majority. The bill in full is as follows:

> Section 1. No woman under the age of 45 years or man of any age, except he marry a woman over the age of 45 years, either of whom is epileptic, imbecile, feeble-minded, or afflicted with insanity,

shall hereafter intermarry or marry any other person within this state. It is also hereby made unlawful for any person to marry any such feeble-minded, imbecile or epileptic person or any one afflicted with insanity, or any person who has ever been so afflicted. Children born after a parent was insane shall not marry except under the above named conditions.

Section 2. No officer authorized by law to issue marriage licenses in this state shall hereafter issue such a license to any persons either of whom is afflicted with any of the diseases mentioned in Section 1 of this act, knowing them to be so afflicted, unless the female party to such marriage is over the age of 45 years.

Section 3. No clergyman or officer authorized by law to solemnize marriages within this state shall hereafter perform a marriage ceremony, uniting persons in matrimony, either of whom is afflicted with epilepsy, imbecility, feeble-mindedness, or insanity, knowing them to be so afflicted, unless the female party to such marriage is over the age of 45 years.

Section 4. Any person violating any of the provisions of this act shall on conviction thereof be punished by a fine of not more than one thousand dollars or by imprisonment in the state's prison for not more than three years, or by both such fine and imprisonment.

MARYLAND.

Smallpox.—There have been 5 cases of smallpox at Aberdeen, Harford County, and the public school and churches have been closed. The first case was imported from Delaware, and was so mild as to be unrecognized. A case has also appeared at Havre-de-Grace in the same county.

Hospital Reports.—According to the annual report of the Cambridge Hospital 529 patients, 397 white and 132 colored, were treated during the year. Fourteen deaths occurred and 265 surgical operations were performed.——There are 484 patients in Maryland Hospital for the Insane, No. 2. The new cottage for epileptics will be commenced early in April.

Baltimore.

Personal.—Dr. Joseph E. Clagett was stricken with apoplexy on March 9.——Dr. Annie G. Lyle, a graduate of Johns Hopkins, 1902, has been appointed assistant to Dr. Esrech at the University of Vienna.——Dr. Martha T. Tinker, assistant resident physician at the Johns Hopkins Hospital has resigned.

Anti-Tuberculosis Crusade.—A large meeting of physicians and others interested in the anti-tuberculosis crusade, was held, March 10, under the auspices of the State Tuberculosis Commission. The city is to be divided into 8 or 10 districts, and agents will visit houses in which there are cases of consumption. Dr. Fulton emphasized the influence of infected houses. Dr. H. W. Buckler spoke of the need of a state institution and said the dispensaries should not treat cases of consumption as it is spread thereby.

Mortality and Smallpox.—The mortality was unusually large last week, being 231, corivalent to an annual death rate of 21.95 per 1,000. Among the deaths were 41 from pneumonia, 11 from bronchitis, 7 from measles and 9 from la grippe. Five new cases of smallpox were reported. The earlier cases were treated as chickenpox by a colored practitioner and there was free intercourse between the patients and a large number of persons who frequented the house. There is considerable likelihood of an epidemic, and the health department is taking extreme precautions.

MASSACHUSETTS.

Tribute to Dr. Gage.—On the resignation of Dr. Thomas H. Gage from the board of trustees of the Worcester Insane Hospital, after a continuous service of 27 years, the board passed resolutions testifying to the faithful, intelligent and valuable service rendered by Dr. Gage to the institution.

Illness at Harvard.—Dr. Marshall H. Bailey, Cambridge, medical visitor to Harvard, reports 5,388 cases of illness during 1902. Nearly a third of the patients merely reported themselves ill and did not wait for any examination or treatment. There were very few serious diseases, throat disorders leading with 307 cases of laryngitis and 185 of tonsillitis.

State Manufacture of Antitoxin and Vaccine.—Two bills are before the public health committee regulating the manufacture of antitoxin and vaccine by the state. The former has been furnished to physicians free by the State Board of Health and has been highly efficient. A movement to have the product put in charge of the State Board of Agriculture is opposed by physicians and druggists alike. It seems probable that a bill will be reported which will put both of them under the control of the State Board of Health.

One Lesson Not Enough.—Dr. Immanuel Pfeiffer, Boston, who so narrowly escaped death from smallpox last year as a result of his obstinate opposition to vaccination, has appeared before the Massachusetts Legislation Committee on Judiciary with a petition that no person shall inject into the body of another person any poison or poisonous substance without the consent of the person operated on. His appeal to lawyers instead of physicians on a matter which concerns public health, shows how few are the medical men who support Dr. Pfeiffer's views in Boston.

MICHIGAN.

Personal.—Dr. Charles G. Jennings, Detroit, has been appointed a member of the State Board of Health.——Dr. Howard A. Grube, major and surgeon, U. S. V., who has served for five years in the Philippines, has returned to Coldwater.

In Trouble.—A. W. Van Bysterveld, Grand Rapids, fined $100 and costs at Grand Rapids for practicing medicine without a certificate, has, it is said, evaded the law by associating with him Dr. George R. Adkin, who, being a legal practitioner, writes prescriptions, the "miracle-worker" keeping officially in the background.——Henry Salisbury, Belding, charged with practicing medicine without a license, pleaded guilty, and was fined $10 and costs.

"Mail Cure" Healers Convicted.—Drs. James M. Peebles, Walter T. Bobo and Charles M. Green, of the "People's Institute of Health," Battle Creek, have been convicted by a jury in the United States District Court, Detroit, of violating the postal laws, by advertising mental cure by mail for all manner of ills. One of the defendants admitted that if a patient at a distance managed to procure Dr. Peebles' signed instructions and followed them faithfully the cure would not be effective if the patients had not paid the fee of $1. A thirty-day stay of proceedings was granted.

Prevalence of Disease.—For February, 1903, compared with the average for February in the 10 years, 1893-1902, scarlet fever, measles, smallpox and whooping cough were more than usually prevalent; and consumption, intermittent fever and remittent fever were less than usually prevalent. For the first time this season, influenza headed the list of those diseases which usually cause the most sickness in Michigan, but was 14 per cent. less prevalent than the average for February in the preceding ten years. Bronchitis, rheumatism, neuralgia and pneumonia were also less prevalent than usual.

The Most Dangerous Communicable Diseases.—Meningitis was reported in Michigan during February, at 9 places; whooping cough at 46 places; diphtheria at 77 places; typhoid fever at 89 places; measles at 105 places; scarlet fever at 179 places; consumption at 193 places, and smallpox at 201 places. Meningitis was reported at 2 places more; whooping cough at 9 places more; diphtheria at 3 places less; typhoid fever at 6 places less; measles at 2 places more; scarlet fever at 6 places less; consumption at 76 places less, and smallpox at 15 places less, in February, 1903, than in the preceding month.

Smallpox Suits.—Seron Bartow has entered suit against Dr. Robert B. Bennett, Grant, for $5,000, alleging that he "falsely and wickedly" gave it out on two occasions that members of the plaintiff's family had smallpox, thereby causing the family to be quarantined for 71 days, preventing him from attending to his duties as a farmer and depriving him of the companionship of his friends and neighbors. The value of this he estimates at a little more than seventy dollars a day. ——Dr. Curtis T. Wolford, Grand Rapids, has been charged by Dr. Thomas M. Koon, health officer, with having failed to report to the health office a case of smallpox.

The Nottingham Bill.—The bill—which we have editorially mentioned—in amendment of medical registration, introduced by Dr. D. M. Nottingham, Lansing, is designed by its author to raise the standard of examination and require all graduates to pass an examination before the medical board, irrespective of what college they come from. It will also favor reciprocity with other states. It is also designed to make the standard of entrance to medical colleges higher, as it requires that the candidate for entrance to such college shall have at least a high school diploma or its equivalent, according to the idea of the board of registration. A vigorous protest has been entered against the bill by the students of the three medical colleges of Detroit, who sent a delegation to Lansing, February 16, to present their protest before the Committee on Public Health of the legislature.

February Mortality.—The total number of deaths reported for February was 2,756, or 100 fewer than the number of deaths in the preceding month. The death rate was 14.4 per 1,000 population, as compared with 13.5 in January. The mortality was slightly higher than that for February of the preceding year. There were 559 deaths of infants under 1 year, 175 deaths of children aged 1 to 4 years, and 874 deaths of persons aged 65 years and over. Important causes of death were as follows: Tuberculosis, 217; pneumonia, 372; typhoid

fever, 34; diphtheria and croup, 52; scarlet fever, 16; measles, 17; whooping cough, 31; influenza, 73; cancer, 126; accidents and violence, 134; smallpox, 5. There was a decrease in the number of deaths from typhoid fever and scarlet fever, while the number reported from influenza was nearly double the number in January. The death rate from this cause, however, was not as high as during the same time last year.

NEW YORK.

Dr. Scollard's Estate.—The will of the late Dr. James I. Scollard, Clinton, was admitted to probate, March 7. The estate, valued at $210,000, is left to the family.

Personal.—Drs. Henry A. Gates, Delhi; Grant C. Madill, Ogdensburg, and Frank W. Sears, Binghamton, have been appointed consulting surgeons to the New York State Hospital for the Care of Crippled and Deformed Children, Tarrytown.

Polluted City Ice.—So much polluted ice is brought to New York City from the Hudson River that a bill has been introduced in the legislature prohibiting the cutting of ice for domestic use between Waterford and Coxsackie on that river, or within 3,000 feet below any town of more than 10,000 inhabitants on said river.

To Protect Buffalo.—State Commissioner of Health Daniel Lewis has appointed Drs. Walter D. Green and Edward Clark health commissioner and assistant health commissioner of Buffalo respectively. This action was taken in order that proper authority might be given to the Buffalo health authorities to protect Buffalo from the source of typhoid fever infection in West Seneca just outside the city limits of Buffalo and outside the jurisdiction of the Buffalo health authorities unless especially vested with power.

New York City.

Enforce Sanitary Crusade.—On March 11, about fifty policemen of Brooklyn were kept busy arresting those who violated the law against expectorating in public places. Up to noon, 14 offenders were arrested, admonished, and paroled until April 2.

Physicians in Insurance Frauds.—In connection with the unearthing of extensive frauds against life insurance companies two physicians, practicing in this city have been indicted: Albrecht Loewit, of 1,833 Lexington avenue, who is out on $5,000 bail, and Francesco Nucci, of 2,072 First avenue, who has furnished $2,500 bail.

Glanders in the City.—According to United States officials there are many cases of glanders in this city, though the records of the health department do not support this contention. Strict quarantine is placed on all infected stables, and every horse in the stable is tested with mallein and his temperature observed for two days before the quarantine is raised. Special attention is given to stables where the horses of milk dealers are kept.

Society Protects Members.—The first case in which the New York State Medical Association assumed the defense of a member sued for malpractice was tried in the Sixth District Municipal Court, March 10. The plaintiff, husband of a patient of Dr. Joseph E. Janvrin, sued the latter for malpractice, alleging the discovery of some error in treatment. This suit followed hard after one in which the physician was the plaintiff and the cause was the non-payment of his bill. Dr. Janvrin won this suit, and the suit for alleged malpractice was also decided in his favor.

Betterment of the Consumptive.—A new sun parlor, costing $10,000, is to be erected on Blackwell's Island for the use of the consumptives there. It will be a one-story structure enclosed in glass on all four sides, and furnished with reclining chairs and sofas. The Tuberculosis Committee of the Charity Organization Society has planned a country sanatorium on a large scale, which shall have permanent buildings, farms and a tent encampment, and shall accommodate 500 patients. Out-door occupation is to be provided for the men on the farm, and for women in horticultural pursuits. It is estimated that the cost will be $530,000, which is thought to be reasonable enough in view of the fact that it has been computed that the total annual loss to the city from tuberculous diseases is at least 23 million. The health department says that an appropriation of only $40,000 will be asked for to begin with, and that it is hoped that the sanatorium may be ready by the middle of June. The society favors some location in Westchester county, while the health authorities are disposed to select a site in Orange County a short distance west of Tuxedo. For a year past the House of Rest for Consumptives has been engaged in remodeling a mansion in that part of the city known as Inwood, for a tuberculosis hospital. This has developed a strong opposition among the wealthy residents in that vicinity, and a physician is aiding this opposition by calling attention to the danger of spreading tuberculosis among the residents near the proposed hospital.

Buffalo.

Personal.—Dr. Burt C. Johnson and Dr. Harry Meade sail for Europe to-day.

Unsanitary Barbers.—Several Italian barbers have been convicted for violation of the ordinances in conducting unsanitary barber shops.

Fatal House-to-House Distribution of Samples.—A three-year-old girl died from the effects of eating sugar-coated pills that were distributed from house to house. The health commissioner is making a thorough investigation of the case.

OHIO.

Scholarship for Physicians' Daughters.—Dr. Elizabeth L. McMahon, Marion, in her will, which has recently been filed for probate, left $8,000 to found a scholarship in Vassar College for daughters of deceased physicians.

Much Typhoid.—Cleveland had more cases of typhoid reported in the week ended February 28 than in any similar period in her history. In the corresponding week of 1902 there were 8 cases; in 1903, 109 cases. The mortality from typhoid for the week was 6.

Abortionist Sentenced.—Dr. H. Negley Teeters, Steubenville, charged with having caused the death of Miss Grace Goodlin of Empire, by a criminal operation, pleaded guilty and was sentenced on March 3 to imprisonment for four years in the penitentiary.

The State Board's Report.—The annual report of the State Board of Medical Registration and Examination shows that certificates were issued during the year as follows: To Ohio matriculates, 323; to graduates on examination, 62; to midwives, 3; to osteopaths, without examination, 120; to osteopaths, with examination, 1. Nineteen applications were rejected, and 13 applications of osteopaths. Two certificates, those of Dr. A. E. Hoskinson and Dr. C. F. Crookes, both of Columbus, were revoked during the year. There were 18 prosecutions under the medical law.

Personal.—Dr. Raymond E. Whelan, who has been serving as captain and assistant surgeon of volunteers in the Philippines, has retired from the Army and will resume practice in Youngstown.——Dr. William A. Burns, Dayton, has been appointed captain and assistant surgeon, O. N. G., and assigned to the Ninth Battalion.——Dr. James Wilson McMurray, Marion, has been appointed inspecting physician for the State Board of Health.——Dr. Henry M. Taylor, Columbus, has returned from California, but will not resume practice on account of continued ill-health.——Dr. Robert E. Swigart, Tiffin, has accepted the position of physician for a large fruit company at Bocas Del Toro, Columbia.

PENNSYLVANIA.

Abortionists Convicted.—Drs. Edwin S. Cooper and J. P. Haun, New Castle, were recently convicted of conspiracy in connection with criminal treatment which led to the death of Mabel Williams of Johnstown.

To Make Barbers Clean.—A bill for the sanitary regulation of barbering and providing for the better instruction of those engaged in the trade has been passed by the legislature. The law applies to first, second and third class cities only.

Child Labor.—A bill has been introduced into the legislature making it unlawful to employ any child under 14 at any labor during public school hours, and working hours for children are limited to 10 hours a day and 55 hours a week.

To Regulate Sale of Poisons and Spirits.—A bill has been introduced into the legislature which provides that it shall be unlawful to sell any medicines, drugs, chemicals, mixtures, anodynes, or any preparation or combination of the same which shall contain any opium or its alkaloids, coca or its alkaloids, or any whisky, brandy, wine or other intoxicating liquors, unless the same is so sold or furnished on the written prescription or order of a physician.

Appropriations for Hospitals.—Bills appropriating the following amounts for various hospitals have passed the house of the legislature: Jefferson Hospital, $260,000; University of Pennsylvania Hospital, $120,000; Medico-Chirurgical Hospital, $290,000, all of Philadelphia; Chester County Hospital, $14,000; Good Samaritan Hospital, Lebanon; Allentown

Hospital, Pittston Hospital, each $15,000, and Homeopathic State Hospital for the Insane, $4,000,000.

Hospital for Poor Consumptives.—The treasurer's report of the Free Hospital for Poor Consumptives shows that the receipts for the year ended February 28 were $70,757.74. The sum of $3,897.99 was collected in glass globes placed in stores and public offices. Within the year 561 patients were cared for, 481 at White Haven Sanitarium, and 80 in other institutions, by payment of their board. Of the patients at White Haven, 33 remained from the preceding year, 258 new cases were admitted, 86 left, 108 were discharged, and 5 died. There are now 100 patients at White Haven. Among the newly elected officers are Dr. Lawrence F. Flick, president, and Dr. Henry M. Fisher, one of the managers.

Philadelphia.

Expectoration Ordinance.—A city ordinance has been passed making it a misdemeanor to spit on the sidewalk, on floors of cars and other public places, the offense punishable by a fine of $1 and costs. Director English has instructed policemen to enforce the ordinance.

Good Water Filtration Secured.—The chief of the bureau of water filtration is much pleased with the city's new filtration system, claiming that the standard for the number of bacteria and for turbidity have both been lowered, and that the work here is better than the best results obtained in other cities. Provision has so far been made for filtration of only a part of the city's supply.

Held as Accessory to Murder.—George Horsey, a negro, a so-called "herb doctor," is held without bail on the charge of being accessory to the crime of murder. He is believed to have sold poison to Mrs. Catherine Danze for the murder of her husband. In the preliminary hearing it appeared probable that Horsey was not only accessory to this crime, but that he has for years furnished "slow poison" in many similar cases of murder. The case is being vigorously and thoroughly investigated.

Contagious Disease Report.—The health record shows that 458 new cases of grave contagious diseases were reported to the authorities for the week ended March 14. Of typhoid fever there were 272 cases, of smallpox 44, of scarlatina 101, and of diphtheria 41. The total number of deaths were 577, as compared with 528 for the same week last year. The records show that about 4,300 cases of such contagious diseases are now under treatment in Philadelphia. The number of new cases of smallpox since January 1 is over 300.

Physicians Endorse Medical Bill.—A mass meeting of many prominent physicians was held on the evening of March 7 in support of the Ray bill introduced into the legislature. The purpose of the bill is to raise the standard of education preliminary to a medical course. The following was adopted as the sense of the meeting:

Resolved, By this mass meeting of the physicians of Philadelphia, believing that the welfare of our citizens will be thereby advanced, that we hereby endorse the original bill of Mr. Ray, and ask for its enactment into a law by our authorities.

GENERAL.

The Ecuador Quarantine against San Francisco has been removed, beginning with vessels leaving that port March 12.

Reception to Dr. Osler.—The Medical Club of Philadelphia will give a reception to Dr. William Osler of Baltimore at the Hotel Bellevue, March 27.

Suspected Cholera Ship at New York.—The Anchor line steamer *Karamania* arrived March 10 at New York from Marseilles, Palermo and Naples. Seven of the steerage passengers and crew had died of an unknown disease. Sixteen had been sick. The symptoms were uniform, and resembled those of Asiatic cholera. No decision could be reached, the bodies having been buried at sea and there not being sufficient data to warrant a definite statement. The ship was fumigated and unloaded and the passengers detained in quarantine for ten days. No other case has developed. It is suggested that the deaths were from ptomain poisoning or from noxious gases from the hold. The matter has excited much discussion.

Mexico and Texas Plague Quarantine.—A quarantine has been declared by Mexico against San Francisco, applying to all Mexican ports, on the ground that the plague at Mazatlan came from San Francisco, and that it had also existed in the latter city as late as January. It will be remembered that this latter allegation is contrary to the advices from competent officials concerning San Francisco. Cuba has placed a quarantine against certain Mexican ports, because of fear of the plague. The State of Texas has quarantined Torreon, Mexico, alleging the existence of plague there. This action has aroused a vigorous protest from Torreon and from the Mexican capital. It is stated that no plague exists in Torreon, but that several Chinamen came there from San Francisco and, as ten days had not elapsed since they left the latter city, they were isolated for observation, and all measures taken in accordance with the sanitary code. El Paso, Texas, has instigated a quarantine against Durango, Mexico. The United States government ordered an investigation of the rumors concerning Torreon and Durango and Texas, by one of its state health officers, ordered a precautionary ten days' quarantine until the cases could be investigated. The physicians at Torreon have declared that no plague exists there and have requested that the quarantine be raised. The authorities of Texas state that this will be done as soon as they are sure that there is no reason for its continuance. The report that plague exists at Villa Union, Mexico, is confirmed. This point is on the route to the interior and has been vigorously quarantined. The infection was doubtless brought from Mazatlan by some of those escaping from that city and, therefore, eluded the quarantine guard. The situation in Mazatlan continues to improve slowly. Over a hundred people are isolated and thirty or forty are in the lazaretto, most of whom are recovering. United States Consul Kaiser at Mazatlan is conducting his affairs in the suburbs of that city, the consulate headquarters being in quarantine. He describes the situation there as follows:

While the plague is still with us, yet it is the general opinion that the worst has passed, and that the plague will soon be a thing of the past. We have had one or two new cases daily, but not any new cases for the last three days. The authorities are doing everything in their power to stamp the fever out, and have burned about 500 houses, with all their contents.

The United States Public Health and Marine-Hospital Service reports that the total number of cases from the beginning of the outbreak to March 6 was 302 and the deaths 250.

FOREIGN.

Monument to Dr. Holub.—The Vienna scientific societies are collecting subscriptions for a monument to the physician and African explorer, Dr. Holub, who died Feb. 21, 1902.

The Medical Study Tour in Germany.—The tour this year will commence September 8 at Wiesbaden, and the party will disband at Cassel, September 20. The watering-places to be visited are those in the Rhine and Taunus provinces.

Berlin Medical School Inspectors.—The "Socialist Democratic" party at Berlin demands a separate medical inspector for each of the 260 public schools. The city council has not the funds for such a number, and has decided that 36 are sufficient for the present, with a salary of $500.

Gold Medal for Pawlow.—The University of Halle has conferred a gold medal on Prof. J. P. Pawlow of St. Petersburg for his research on digestion. His name is pronounced as if spelt Pavloff, which is also the pronunciation of the German form, Pawlow, by which he is best known to science.

Circulars for Prophylaxis Against Typhoid and Dysentery.—The German Council of Health has issued two more pamphlets like those it has distributed, which treat of tuberculosis. Koch, Kirchner and Krieger wrote the text. They describe the disease, its cause, treatment, modes of contagion, disinfection, etc.

A traveling post-graduate medical school, to visit all the cities of sufficient size and have clinics and lectures by eminent men is proposed in Germany. The practitioners in the surrounding territory would thus gather for a week or two once a year in their nearest large town. Museums, etc., would be carried.

Prizes for Milk Hygiene.—The Hamburg Exposition of Milk Hygiene offers thirty-one prizes for the best method of cleaning bottles, for the best contribution on the subject of modifying milk for infants, of keeping milk, sterilizing, etc. Also for popularly worded pamphlets on these subjects. The prizes range from $125 downward.

Compulsory Notification of Diseases in France.—By a decree, signed February 10, the president of the French Republic officially proclaimed the list of diseases for which notification is compulsory, adopting without change the list recommended by the Académie de Médecine. It was given in The Journal of February 28, p. 612.

Sale of a Medical Practice.—In a recent suit in France and another in Germany, the courts decided that the plaintiff suing for payment for the sale of a medical practice had no

case, as a medical practice can not be bought and sold. In one of the suits the sale of the furnishings and practice had been made by the widow of a physician.

French Congress of Alienists and Neurologists.—The thirteenth annual congress of French alienists and neurologists will be held at Brussels, Aug. 1 to 8, 1903. The subjects announced for discussion are "Catatonia and Stupor," "Histology of General Paralysis," and "Treatment of Agitation and Insomnia in Mental and Nervous Disease."

The Esmarch Medal.—A gold medal was presented to von Esmarch on the occasion of his recent birthday. It is now proposed to give a bronze replica of the medal to persons or societies that have distinguished themselves in the first aid or, Samaritan movement, as it is called in Germany. The first medal to be thus bestowed was presented to Prince Henry of Prussia, February 14.

The Social Medical Congress in Austria.—Dissatisfied with the efforts of the existing national medical organizations on behalf of their material interests, the physicians of Austria are organizing a national "*Sozial-ärztlichen* Congress," to discuss in general conclave the important questions of the day. The *Klin. Therap. Wochenschrift* quotes figures to the effect that 130 local medical associations are sending delegates.

Campaign Against Charlatans in Germany.—The last week brings the account of the condemnation of a faker at Plauen to a fine of $25 for assuming a pseudo-medical title. At Hochlausen a faith-healer was condemned to ten days' imprisonment, and at Carlsruhe the director of a so-called hydropathic institute was fined $75 for having treated a cancer subject with cold water alone. The authorities are discussing more stringent regulations against charlatans.

Charlatan Examinations.—A public examination of students trained in two Berlin "nature-healing" establishments was recently held there, the proceedings modeled on those of medical colleges. The report in the "*Nature-Healers' Gazette*" stated, among other items, that the students "passed a successful examination in the gynecologic examination of twelve male and twelve female patients, the latter suffering from gynecologic affections."

The Bulletin de l'Association Gen. des Medecins de France.—The newly created organ of the French Medical Association starts out with the intention, we are told, to fill in France the place occupied by the *British Med. Journal* in England and THE JOURNAL in this country. The French medical press is inclined to look askance at the newcomer, and the *Gazette Medicale de Paris* remarks that there is little chance of its realizing its ambition "unless it gets an American or English brain to take charge of it."

Correspondence.

The Biographic Clinics of Dr. Gould.

CHICAGO, March 14, 1903.

To the Editor:—The medical profession is under many obligations to Dr. George M. Gould, the vigorous editor of *American Medicine*. The last product of his fertile brain and productive pen is the "Biographic Clinics," a book of 233 pages. In writing this wonderful book he has done pioneer work in a most important department of medicine. He has shown conclusively that five of the greatest men in history were the subjects of eyestrain, which was responsible for all the agonies that made the busiest and most useful epochs in their lives a constant misery. The analysis of the symptoms related by themselves or their biographers is so logical that no doubt can be left in the minds of the careful reader concerning the correctness of the author's conclusions. There can be no doubt that thousands are affected in a similar manner to-day, and as any competent oculist can secure the necessary relief this class of patients should be reached by the profession. This little book should be in the hands of every physician and teacher, as it treats of a subject of a medical affection which, when overlooked or neglected, will bring ailments that will make life a constant misery, if not a total failure. N. SENN.

The Identity of Nerve Force and Electricity.

WASHINGTON, D.C., March 9, 1903.

To the Editor:—Referring to the paper of Dr. J. Emmet O'Brien, page 630 et seq. of THE JOURNAL, March 7, in which he claims priority as to the identity of electricity and nerve force, etc., I very respectfully suggest that on reference to the Transactions of the Medical Society of the District of Columbia, of Dec. 5, 1883, it will be found that the general principles of his paper have been long since anticipated by one on "Electricity and Nerve Force" presented by,

Very respectfully yours, JOSEPH T. HOWARD, M.D.

Maternal Impressions.

AIKIN, MICH., March 14, 1903.

To the Editor:—Baby S., a healthy seven-pound female baby, was born at full term on March 1, 1903. She has a prominent birthmark covering the left thumb and upper part of the arm, over the shoulder and slightly down the back. The mother had an accident three months before delivery. She was wearing an outing-flannel gown, the left sleeve of which was lighted from a match, and in a flash an area of the sleeve corresponding to the baby's birthmark was burned.

A. G. BELSHEIM, M.D.

Family Care of the Insane.

LEXINGTON, KY., March 16, 1903.

To the Editor:—Your editorial in the last number of THE JOURNAL, on family care of the harmless insane, leads me to suppose that you do not know that it has been continuously in use in Massachusetts since 1885. It was due, I believe, to the efforts of Dr. Henry R. Stedman of Boston, who wrote a most exhaustive paper on the subject. The matter was reviewed at the last meeting of the American Medico-Psychological Association. GEO. P. SPRAGUE.

Book Notices.

THE MALARIAL FEVERS OF BRITISH MALAYA. Studies from Institute for Medical Research, Federated Malay States. By Hamilton Wright, M.D. (McGill), Director of the Institute for Medical Research, Federated Malay States. Paper. Price 3 shillings net. Philadelphia: P. Blakiston's Son & Co. 1902.

This report, as stated by the author, does not represent an extensive study of malarial fevers of the British portion of the Malay peninsula, but he offers it as a first step, hoping it will call attention to the value of the field to European students of malaria. So far as the existing forms of malaria are concerned, they seem to be largely those met elsewhere. There is a predominance of the malignant tertian type, the mild tertian being only second in frequency. It appears that Europeans seldom contract malaria within their own quarters within the larger centers of population. They can nearly always date their infection to some out-station or jungle work in a specially malarial region. It is noticed as a remarkable fact that in a large prison where one species of anopheles abounds, malaria is almost unknown. The greatest sufferers seem to be the coolies and natives; among them are found the chief figures of morbidity and mortality. The tin mines of the Malay peninsula are ideal fever spots. The natives who live in large centers and neglect the hygienic measures followed by Europeans also suffer to a certain extent, and the native police are to a large extent agents of the transmission of the disorder from one section to another. A policeman breaks down in health in one place and is sent to another locality, which he also infects. This is a point to which Dr. Wright very properly calls the attention of authorities, as it is avoidable. The species of mosquitoes have been studied and the work contains valuable data in regard to prophylaxis and treatment, which he says is needed in these parts of British India. The first essentials are sanitary precautions, hydraulic drainage, clean surroundings and a well-regulated passion for quinin. The larger part of the work is a narration of cases and it concludes with accounts of the aspects of malaria in the different sections, contributed by government surgeons. In the very conclusion of the work an interesting statement is made by one of these that so far as known no case of blackwater fever has ever occurred in the Malay peninsula, notwithstanding the large doses of quinin that are habitually employed. This would seem

to contradict the quinin theory of the production of this disorder.

Lehrbuch der Ohrenheilkunde. Für Aerzte und Studirende, von Prof. Dr. L. Jacobson und Dr. L. Blau, Ohrenaerzten in Berlin. Dritte, neu beurbeitete Auflage des Jacobson-schen Lehrbuches, mit 345 Abbildungen auf 19 Tafeln. Leipzig: Verlag von Georg Thieme. 1902.

Professor Jacobson, whose work for sixteen years at the Ear Clinic of the University of Berlin gave him a wide acquaintance, and whose contributions to Schwartze's "*Archiv*" gave him a name in the otologic world, addresses a larger medical audience in this volume of more than 500 pages. It is intended for both students and general practitioners, and the details of more interest to the specialist are in smaller type. There are 345 illustrations, of which there are a number of new ones in this, third, edition (showing the radical operation, the recent plastic methods following the former, the method of exposing the middle cranial fossa and the transverse sinus, ligation of the jugular vein, and lumbar puncture).

The report of the complete literature is brought up to the end of the year 1901. Dr. Blau's command of this part of the work is apparent. It is to be expected, because of his being chief editor of the *Encyclopædie der Ohrenheilkunde*. The rapid progress of the specialty, the authors state, caused them to make additions to every department. The greatest changes are to be found in the chapters on normal hearing; the methods of examination; the differential diagnosis between diseases of the sound conducting and perceiving apparatus; on pneumatic massage of the middle ear; on chronic middle ear suppuration; on the "dry chronic middle ear catarrh"; on trephining the mastoid process, and on the radical operation; on deaf-mutism; on otitic diseases of the brain, meninges and sinuses; on otitic pyemia and septicemia; on aural complications in scarlet fever, diphtheria, locomotor ataxia, and tuberculosis. Therapeutics is freely discussed. The chapter on the value of the various methods of testing the hearing and of making exact differential diagnoses between diseases of the sound perceiving and conducting apparatus is written by Professor Jacobson alone. His exceedingly critical review of this important subject is of the greatest interest.

The Mind of Man. A Text-Book of Psychology. By Gustav Spiller. Cloth. Pp. 552. Price, $2.75 net. London: Swan Sonnenschein & Co., Ltd. New York: The Macmillan Co. 1902.

The study of psychology is a profitable side-issue for the physician to take up for many reasons. The present volume is a contribution that most medical readers will find intelligible and interesting. Its treatment of the subject is that of the sensational school and there are probably many of us who will disagree with the author in some of his views and conclusions. The rejection of the noumenal ego will be to some of us a little hard to accept and his argument for it from the facts of insanity appear fallacious, but it seems to be the outcome of the line of reasoning of a large number of psychologic thinkers. Some subjects are very rapidly touched on and the treatment seems to us unsatisfactory, for instance, his few remarks on the subject of character. The characteristic of the author is self-confidence, which is very noticeable throughout in his assertiveness and his comments on other authors. He, however, ably handles his subject and some portions of the work are very interesting reading. His study of Shakespeare, for example, will be to some a novel treatment of the subject. The style of the book is interesting and it is throughout intelligible. It is certainly not the heavy reading which some works on psychology are found to be.

Disinfection and Disinfectants. A Practical Guide for Sanitarians, Health and Quarantine Officers. By M. J. Rosenau, M.D., Director of the Hygienic Laboratory and Passed Assistant-Surgeon U. S. Public Health and Marine-Hospital Service, Washington, D. C. Illustrated. Cloth. Pp. 353. Price, $2.00 net. Philadelphia: P. Blakiston's Son & Co. 1902.

Dr. Rosenau has furnished a convenient manual of disinfection which can not fail to be of use to physicians, health officers and others, in fact, to everyone who has occasionally the need of such a work. He says he has made mistakes like everyone else in learning what, how and when to disinfect, and the book is written to aid others who have to battle with infection and communicable diseases. It is based on experience as well as knowledge gained otherwise and has, therefore, its special value as a work of a practical expert. It is a book the substance of which ought to be familiar to every physician and especially to every local health officer in the country.

Practical Obstetrics. A Text-Book for Practitioners and Students. By Edward Reynolds, M.D., Visiting Surgeon to the Free Hospital for Women, and Franklin S. Newell, M.D., Assistant in Obstetrics and Gynecology in Harvard University. Illustrated with 252 Engravings and 8 Colored Plates. Cloth. Pp. 553. Price, $3.75 net. Philadelphia and New York: Lea Brothers & Co. 1902.

This volume is the result of the practical success of an earlier work by one of the authors, which did not attempt to go so extensively into the subject as does the present. It is a convenient, reasonably condensed, and a practical handbook on the subject. It is thoroughly illustrated and has an excellent index. While not so full and complete as many other works on the subject, we believe, to a large class, it will be found even more popular because of its conciseness. The authors say, if it appears to settle most points of practice dogmatically, the fault has been intentionally committed on the belief that the description of one justifiable plan of treatment is more likely to be of advantage to the student than the extended discussion of the advantages and disadvantages of many methods. This explains the standpoint from which the book has been written. It is practical, and elegantly gotten up.

A Handbook of Materia Medica, Pharmacy and Therapeutics, Including the Physiological Action of Drugs, the Special Therapeutics of Disease, Official and Practical Pharmacy, and Minute Directions for Prescription Writing. By Samuel O. L. Potter, A.M., M.D., M.R.C.P. Lond., Formerly Professor of the Principles and Practice of Medicine in the Cooper Medical College of San Francisco. Ninth Edition, Revised and Enlarged. Cloth. Pp. 951. Price, $5.00. Philadelphia: P. Blakiston's Son & Co. 1902.

The author has added many things to what appeared in previous editions, some from his experience in the tropics while serving with the Eighth Army Corps and at general headquarters in the Philippines. In this respect it has an advantage over some other works that have recently appeared. A number of articles in the work have been rewritten and others expanded by incorporation of new items. The work, as a whole, has been, as the author says, critically revised.

Marriages.

Thomas J. Reid, M.D., to Miss Caroline Wolcott, both of Chicago.

Philip Newmark, M.D., to Miss Marie C. Fleck, both of Los Angeles, Cal., March 15.

Edward Lee Beatie, M.D., Kansas City, Mo., to Miss Emma Gertrude Rockwell of Chicago, March 10.

Samuel A. Huffman, M.D., Chesterfield, Ill., to Miss Clyde McQuerry of Greenfield, Ill., February 26.

Robert J. Heavenridge, M.D., to Miss Cora McClenning, both of Hannibal, Mo., at New London, Mo., March 2.

John R. McDill, M.D., Manila, P. I., formerly of Milwaukee, Wis., to Miss Anna Josephine Neale of San Diego, Cal., at Manila, January 27.

Deaths.

William Phipps Munn, M.D. University of Michigan, Ann Arbor, 1886, died at his home in Denver, March 12, from hemorrhage of the lungs, aged 38. He was born in Pittsburg, and after his graduation in medicine practiced for four years in Allegheny. He was then compelled on account of ill-health to go to Colorado, and settled in Denver. He entered immediately into college work and was given the chair of histology and pathology in Gross Medical College. In 1892 he was made professor of genito-urinary diseases and clinical surgery in the University of Denver, and occupied this chair until 1897. He was a member of the American Medical Association; president of the Colorado State Medical Society in 1900-1901; member and some-time president of the Denver and Arapahoe Medical Society; health commissioner of Denver 1895 to 1899; for ten years a member of the board of health, and recently its president. He was always active in all that pertained to the good of the medical profession and was one of the leaders in the work of reorganization in Colorado.

Arthur Vallee, M.D. Laval University, Quebec, 1875, who filled in turn the chairs of toxicology and legal medicine, obstetrics, deontology, history of medicine and mental diseases; a member of the Psychologic Society of Paris, and the Society of Mental Medicine of Belgium; vice-president of the Provincial Medical Council and for a long time superintendent of the Beauport Insane Asylum, Quebec, died at his home, January 23, after an illness of four months, aged 54.

Charles Henry Ohr, M.D. University of Maryland, Baltimore, 1834, mayor of Cumberland, Md., for seven years; acting assistant surgeon U. S. Army during the Civil War; member of state senate; vice-president and president of the Medical and Chirurgical Faculty of Maryland, died at his home in Cumberland, March 3, aged 92. He retired from practice several years ago.

George W. Bishop, M.D. Jefferson Medical College, Philadelphia, 1848, a practitioner of medicine until 1865, afterward state senator from Worcester County, Md., assistant treasurer of the United States at Baltimore, and later treasurer of Worcester County, died suddenly from heart disease at his home in Snow Hill, Md., March 6, aged 76.

Joseph Christopher Shepard, M.D. New York University, 1860, who afterward studied in France and then served throughout the Civil War on the Confederate side, one of the most prominent physicians of Wilmington, N. C., died at his home in that city, March 5, from heart disease, after an illness of ten days, aged 63.

Henry R. Porter, M.D. University of Georgetown, Washington, D. C., 1872, of Bismarck, N. D., died at Agra, India, March 3, from heart disease, while making a trip around the world, aged 55. He was an acting assistant surgeon in the Army, and served with Reno in the campaign in which Custer was killed.

John R. Casey, M.D. St. Louis Medical College, 1857, for nearly half a century a practitioner of Joliet, Ill., for ten years surgeon to the state penitentiary, a member and once president of the Will County Medical Society, died at his home in Joliet, March 1, from diabetes, after a long illness, aged 68.

James J. Larkin, M.D. Chicago Medical College, 1880, died suddenly at his home in South Chicago, from apoplexy, March 12, aged 49. He was a member of the Chicago Medical Society and Physicians' Club, and was surgeon to the South Chicago Hospital.

William Campbell Goodlett, M.D. University of Pennsylvania, Philadelphia, 1849, formerly a surgeon in the United States Army and in the Confederate service, died at his home in St. Louis, March 1, after an illness of one year, aged 80.

Ashley A. Webber, M.D. New York University, 1888, an authority on gunshot wounds and an expert of national repute with the rifle and revolver, died from Bright's disease at his home in Brooklyn, February 19, aged 39.

Enoch P. Jones, M.D. Eclectic Medical Institute, Cincinnati, 1854, died at his home in Marion, Ind., from paralysis, after an illness of two months, February 26, aged 75. He retired from practice in 1900.

Levi B. Ward, M.D. Kentucky School of Medicine, Louisville, 1896, member of the Colorado State and Fremont County medical societies, died at his home in Canon City, Colo., February 24, aged 37.

James Henry Dugan, M.D. College of Physicians and Surgeons, Chicago, 1899, of La Salle, Ill., died March 2, after an operation for appendicitis, at Mercy Hospital, Chicago, aged 30.

David F. Rupp, M.D. Kansas City Medical College, 1879, health officer of San Diego, Cal., died at his home in that city, February 25, from pneumonia, after an illness of ten days, aged 53.

James C. Patton, M.D. Medical College of Evansville, Ind., 1850, a veteran of the Civil War, died at his home in Francisco, Ind., where he had practiced for 53 years, February 19, aged 76.

Charles F. Patterson, M.D. Jefferson Medical College, Philadelphia, 1878, died at his home near Coal Grove, Ohio, February 10, from consumption, after an illness of many months.

George W. Smith, M.D. Rush Medical College, Chicago, 1894, of Monongah, W. Va., died at the Cook Hospital, Fairmont, W. Va., February 26, after an extended illness, aged 28.

Alexander Stanley Hancock, M.D., died at his home in New York City, February 28, from starvation due to a cancer of the throat, aged 65. He retired from active practice in 1893.

Charles F. Rideout, M.D. Medical School of Maine, Bowdoin College, Brunswick, 1884, died at his home in Bath, Maine, February 28, from pneumonia, after a brief illness, aged 45.

Henry Edward Newell, M.D. Long Island College Hospital, Brooklyn, 1873, died at his home in West Derry, N. H., February 24, after a long and painful illness, aged 51.

Edwin E. McCall, M.D. Baltimore Medical College, 1894, health officer of Lima, Ohio, died at his home in that place from uremia, after a short illness, March 23, aged 37.

John N. Kendig, M.D. University of Maryland, Baltimore, 1898, of Akron, Ohio, died at a hospital in Cincinnati, Ohio, February 26, from cerebrospinal meningitis, aged 28.

Theodore A. Grover, M.D. Starling Medical College, Columbus, 1869, formerly of Pittsburg, Pa., died suddenly at Wilmington, Del., March 6, from paralysis, aged 63.

John Graham, M.D. Eclectic Medical Institute, Cincinnati, 1878, died at his home in Plainville, Ill., February 23, from kidney disease of long standing, aged 65.

Francis Rourk, M.D. University of Maryland, Baltimore, 1865, died suddenly at his home in Detroit, Mich., February 22, aged 61. He was a veteran of the Civil War.

A. D. Griffin, M.D., who practiced medicine in Keokuk and Benton counties, Iowa, for more than half a century, died at his home in Vinton, Iowa, February 25.

J. R. Simms, M.D. Medical School of the Valley of Virginia, Winchester, 1849, died suddenly, February 27, at his home in Linden, Cal., aged 82.

William H. Baird, M.D. Tulane University, New Orleans, 1869, of Oxford, Miss., died at Jackson, Tenn., March 5, after an invalidism of four months.

Alexander C. Peters, M.D., for more than forty years a practitioner of Newark, N. J., died from paralysis at his home in that city, March 1, aged 63.

T. W. Wright, M.D. Keokuk (Iowa) Medical College, died at his home in Farmington, Iowa, from typhoid fever, March 1, after an illness of two weeks.

Daniel C. Dickinson, M.D. Medical College of Virginia, Richmond, 1878, died at his home in Union Hall, Va., March 6, after a brief illness, aged 45.

Henry W. Richter, M.D. New York University, 1861, died at his home in Brooklyn, N. Y., March 4, from paralysis, after a year's illness, aged 63.

William F. G. Noetling, M.D. University of Heidelberg, Germany, 1842, died at his home in East Hampton, Conn., February 28, aged 83.

Richard D. Greene, M.D. Bellevue Hospital Medical College, New York, 1867, died at his home in Lexington, Ky., February 25, aged 63.

Lester Joslin, M.D. Cleveland Medical College, 1867, died at his home in Ionia, Mich., February 26, from a carbuncle, after a short illness.

William J. Enders. M.D. Miami Medical College, Cincinnati, died at his home in Hamilton, Ohio, March 7, from pneumonia, aged 26.

Rutherford R. Price, M.D. Western Pennsylvania Medical College, Pittsburg, 1900, of Toronto, Ohio, died at Phoenix, Ariz., February 26.

Elliott W. Leech, M.D. Kentucky School of Medicine, Louisville, 1891, died at his home in Shelbyville, Ind., March 5, aged 70.

L. W. Bishop, M.D. Medical College of Ohio, Cincinnati, 1870, died at his home in Batavia, Ohio, February 27, from paralysis.

John N. Davis, M.D. Eclectic Medical Institute, Cincinnati, 1880, of Boulder, Colo., died at the Denver Hospital, February 22.

Samuel C. Hanford, M.D. New York University, 1845, died at his home in Hempstead, Long Island, N. Y., February 24, aged 80.

William Johnson, M.D. Rush Medical College, Chicago, 1880, of Grant City, Mo., died at Boulder, Colo., February 17.

Reginald H. Reid, M.D. Detroit College of Medicine, formerly of Detroit, died at Hils, Hawaii, recently, aged 28.

Edward R. Kittoe, M.D. Chicago Medical College, 1869, died suddenly at his home in Galena, February 18, aged 57.

William H. Koogler, M.D. University of Iowa, Iowa City, 1873, died at his home in What Cheer, Iowa, February 13.

James M. Gears, M.D. Fort Worth (Texas) University, 1901, of Poolville, Texas, died recently at Fort Worth.

James M. Glass, M.D. Fort Worth (Texas) University, 1901, of Poolville, Texas, died recently at Fort Worth.

Deaths Abroad.

Dr. Michaux, surgeon of the Messageries Maritimes steamer *Laos*, died at sea from the effects of atropin administered by accident, January 24.

Rafael Zoldivar, M.D. National University, Guatemala, statesman, and twice president of Salvador, and more recently minister of that republic in Washington, died in Paris, March 3.

F. Cramer, M.D., Würzburg, the well-known German surgeon, died from influenza-pneumonia at his home in Wiesbaden, in February, aged 56.——**A. J. A. Guimaraes, M.D.**, Bahia, assistant superintendent of the Federal Laboratory of Bacteriology, died at Rio Janeiro, February 12, aged 32.——**D. Cervesato, M.D.**, Padua, private docent and professor of pediatrics at Padua and later at Bologna, died at his home from appendicitis, January 24, aged 51. He is the author of numerous works on his specialty and other subjects.

Dr. M. Weiss died at Vienna, aged 74. He resided in Prague or its vicinity until 1897, and was prominent in all matters affecting the general welfare of the profession. He was also a frequent contributor to medical literature, and honorary member of several medical societies.——**Dr. Emil Gold**, director of the Model Hospital at Bielitz, which owes its preeminence to his efforts, died recently, aged 44, from the effects of a stroke of paralysis last year, due to overwork.——**C. Gallozzi, M.D.**, professor of surgery and dean of the medical department of the University of Naples, died there February 11, aged 84, from cerebral embolism.——**F. Loesch, M.D.**, professor of internal medicine at Kiev, aged 63, died from apoplexy. He has published numerous works in Russian and foreign medical literature.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

THE HORSELESS CARRIAGE.

SPOKANE, WASH., Feb. 24, 1903.

In THE JOURNAL of February 14 a communication is published from Dr. Oscar S. Gilbert, Boulder, Colo., requesting information on the use of the automobile by the physician, and I here give my experience.

Fifteen months ago I purchased a light runabout of a standard make, weighing about 850 pounds, having, as claimed by the maker, a 4½ horse-power gasoline engine, costing laid down here $750. I used this wagon eleven months (less one month during which it was laid up for repairs), running it during that period about 6,000 miles, most of it on gravelly roads, which were comparatively level, and muddy only two months.

Repairs alone during that period cost something over $25 a month, gasoline for the same period about $6 a month. After the first few months I had sufficiently mastered the art of navigation of a gasoline engine to enable me to feel reasonably sure that so far as my engine was concerned I would be able to return home from almost any trip I took.

While this horse-power is not sufficient to take a wagon of this weight up a grade to exceed 15 per cent. with any degree of rapidity, by careful usage and stopping occasionally to speed up the motor, a much heavier grade may be made.

Before the eleven months were out I had spent at least another $100 in replacing worn-out parts, such as chains, front and rear sprockets, tires, etc. With these parts, I expect to have another two summers' use simply as a pleasure rig for my wife, by avoiding hard and muddy trips.

Three months ago I purchased a phaeton of a standard make, weighing about 1,100 pounds, with three cylinders, and guaranteed ten horse-power, large, wooden wheels, top, and all the conveniences of an up-to-date doctor's rig, costing here $1,400. This wagon has been run through the severe muddy winter weather, but I have had considerable annoyance from break-downs of small parts, none serious enough to lay me up for more than a few hours, but serious enough to have left me stranded high and dry had I been making country trips instead of city runs, where, by the use of the telephone, the repair man can always be gotten quickly.

I had hoped when I purchased this wagon to be spared such small annoyances, but for some reason unknown to me the manufacturers have not yet sufficiently perfected their wagons to accomplish this, as has been proven to me both by my own experiences and those obtained from reading the physician's number of a late automobile journal.

There appear to be so many little break-down possibilities, that even now I would not feel safe to leave the city limits very far with either of my wagons. Pneumatic tires, even the best, are liable at any time to be punctured or perforated by pressure or nails, and it is no small matter to repair them outside of a well-regulated shop. The sun and planet transmission gear, the one generally in use, is a very complicated affair and often a source of trouble from breakage.

The lubrication requires constant care and is liable at any time to become a source of annoyance. The usual chain transmission is a delicate affair, and likely to break or stretch. The rear sprocket wheel, being a differential gear, may at any time cause trouble by breaking of pins or small parts. The matter of circulation of water in the small rig for cooling the engine is most important, the process being by centrifugal pump, which, with its connections, may at any time get out of repair, and where there is no water circulating, the packing in the cylinder head soon burns out, and it is laid up for a few hours, even if you are willing to stop on the road and pack your own engine. The sparking arrangement in either rig is at any time liable to give trouble.

I could go on for a half hour describing troubles that may be had by the automobilist, but think I have given a sufficient number to prove the necessity of keeping the wagon within a reasonable distance of a skilled mechanic and gasoline engineer, whose almost constant attention is required to get good service out of it.

There is no doubt that much time can be saved on the road and many more calls made with an automobile than with any form of horse and wagon, but to accomplish these results considerable experience, expense, and annoyance must be had. I have no doubt that there will be made in the near future a wagon free from many of the annoyances and dangers which I have outlined, but until then, my advice to physicians who expect to run their wagons at all times on all kinds of roads and places, would be not to buy an automobile.

Yet, to a man able and willing to pay for the extra expense mentioned above, I believe it will bring him more pleasure and exhilarating exercise than the same amount of money invested in any other way, but in buying one for use off of the paved road, get a gasoline rig in which there is at least a horse-power for each one hundred pounds weight of the wagon, and the entire weight of the wagon should not much exceed one thousand pounds. Get one with double detachable tires, with wooden wheels, and a two or three-cylinder gasoline engine, with a cylinder head which screws in, and does not require packing, avoid centrifugal pumps and vibrators also if possible, and expect to use it at least three months before a sufficient knowledge of the wagon has been gained to get much pleasure out of it. The electric and steam wagons are still more expensive and difficult to operate, the latter requiring too much time for starting and water and gasoline for running.

C. P. THOMAS.

State Boards of Registration.

The Modified Montana Medical Law.

Two bills bearing on the medical practice law of Montana have passed through the legislature of that state; one making provision for appeals, providing that all appeals against the decisions of the board of medical examiners shall be tried before a jury of six physicians, not less than two of whom shall be of the same school of medicine as the appellant. This act takes out of the hands of the lay judges and juries the decision of questions as to professional conduct, standing, etc., of those who have come under the penalties provided for by the law.

The other amendment provides for reciprocity. It changes the section of the law that lays down the conditions under which licenses can be granted by inserting after the provision for granting of said license the following:

Provided, however, that in all cases where an applicant for a certificate under this Section shall produce and exhibit to said board of examiners a certificate from a board of medical examiners, duly appointed and existing under the laws of any state of the United States and recognizing certificates or licenses from this state, certifying to the fact that the person presenting such certificate is duly and well qualified to practice medicine and surgery in the state issuing said certificate, and that said board issuing said certificate has subjected the applicant to a thorough examination to ascertain this fact, or certifying to the fact that the person presenting such certificate is duly and well qualified to practice medicine and surgery in the state issuing said certificate; and to the further fact, if such is the case, that said applicant was exempt from examination under the provisions of the law of said state, by reason of his residence in said state in the active practice of medicine and surgery at the time of the passage in said state of said law requiring the examination of applicants to practice medicine and surgery; he or she may, at the discretion of said board of examiners, on paying the fee required of applicants for examination under the provisions of Section 607 of this article, and otherwise complying with all the requirements of this article, receive from said board of examiners a certificate to practice medicine and surgery within this state, and on filing said certificate with the county clerk of the county in

which he resides, as is provided in Section 604 of this article, he shall be a legally qualified practitioner of medicine and surgery in this state.

Association News.

New Members.

New members for the month of February:

ALABAMA.
Gresham, W. A., Russellville.
Hargrove, R. J., Tuscaloosa.
Kernachan, W. J., Florence.
Lightfoot, P. M., Crosskeys.
Persons, H. S., Montgomery.
Robertson, J. W., Brundidge.
Oates, W. H., Yellow Pine.

ARKANSAS.
Barlow, E. E., Dermott.
Hipolite, W. W., DeVall's Bluff.
Hume, H. C., Paragould.
Pope, M. Y., Monticello.
Smith, R. N., Augusta.
Stanley, A. C., Tillar.
Murphey, N. E., Clarendon.
Hebert, G. A., Hot Springs.
Waldrop, J. G., Wheatley.

CALIFORNIA.
Goodfellow, G. E., San Francisco.
Brown, M. W., Alameda.
Key, J. W., Pinole.
Wilder, E. M., Sacrameto.

COLORADO.
Hoagland, H. W., Colorado Sprgs.
Sipe, W. P., Cripple Creek.

CONNECTICUT.
Covley, M. L., Waterbury.

DISTRICT OF COLUMBIA.
Baker, R. W., Washington.
Boyd, J. C., Washington.
Belt, E. O., Washington.
Mullins, J. B., Washington.

Medical Organization.

Hempstead County (Ark.) Medical Society.

This society was organized February 13 by Dr. J. S. Corn, Nashville, councilor of the Sixth District Arkansas Medical Society, and elected the following officers. Dr. Hosea J. F. Garrett, president; Dr. B. S. Rhea, vice-president, and Dr. J. H. Weaver, secretary and treasurer.

Box Butte County (Neb.) Medical Society.

In accordance with the suggestion of the American Medical Association and the Nebraska State Medical Society the physicians of the county met in Alliance, February 27, and organized this society, with Dr. Harvey H. Bellwood, Alliance, president; B. F. Bettleheim, vice-president, and Dr. J. E. Moore, Alliance, secretary and treasurer.

Coffee County (Tenn.) Medical Society.

Dr. James B. Murfree, Jr., Murfreesboro, met the physicians of Coffee County at Manchester and assisted them to reorganize the county society with the following officers: Dr. James B. Cowan, Tullahoma, president; Dr. A. F. Vincent, Manchester, vice-president; Dr. G. W. Taylor, Summitville, secretary and Dr. Erin P. Vaughan, Manchester, treasurer.

Lewis County (Ky.) Medical Society.

The physicians of Lewis County held a meeting at Vanceburg, March 11, and organized a county society, after a talk by Dr. Joseph E. Wells, Cynthiana, councilor for that district, adopting, without change, the plan of organization of the American Medical Association. Dr. Lewis A. Grimes, Concord, was elected president, and Dr. Aaron F. Hill, Vanceburg, secretary.

Greenup County (Ky.) Medical Society.

The physicians of Greenup County met at Greenup, March 12, and organized a county society, after an address from Dr. Joseph E. Wells, Cynthiana, district councilor. The plan of organization of the American Medical Association was adopted without change, and the following officers were elected: President, Dr. A. A. De Bard, and secretary, Dr. Romulus C. Biggs, both of Greenup.

Wayne County (N. Y.) Medical Association.

Physicians of the county met at Lyons, February 12, and organized a new county medical association to be in affiliation with the New York State Medical Association and the American Medical Association. The following officers were elected: Dr. James W. Putnam, Lyons, president; Dr. Mary A. Brownell, Newark, vice-president; Dr. George S. Allen, Clyde, secretary, and Dr. Darwin Colvin, Clyde, treasurer.

Bracken County (Ky.) Medical Society.

The physicians of Bracken County met at Brooksville, March 10, and after listening to an address by the councilor of the district Dr. Joseph E. Wells, Cynthiana, organized a county society, with Dr. David J. Wallin, Brooksville, president and Dr. Vannie E. Smith, Powersville, secretary. The

society adopted without change the constitution and by-laws prepared by the American Medical Association.

Caldwell County (Ky.) Medical Society.

The members of the medical profession of Caldwell County met at Princeton, March 12, and after a very interesting and instructive address by Dr. William W. Richmond, Clinton, president of the Kentucky State Medical Association, formed a county society, electing Dr. R. S. Coleman president and Dr. R. Woods Ogilvie secretary, both of Princeton. The constitution and by-laws of the American Medical Association were adopted without change.

Plaquemines Parish (La.) Medical Society.

The medical fraternity of Plaquemines Parish met at Pointé à la Hache on February 5, and organized a parish society, in affiliation with the Louisiana State Medical Association. Dr. John N. Thomas, Quarantine, was elected president; Dr. Valery O. Schayot, Pointé à la Hache, vice-president; Dr. J. F. Buquoi, Pointé à la Hache, secretary-treasurer. The society adopted the constitution and by-laws recommended by the American Medical Association for component societies.

Cincinnati Academy of Medicine.

The annual election, held March 2, resulted as follows: President, Dr. Byron Stanton; vice-presidents, Drs. John L. Cleveland and Burwell P. Goode; secretary, Dr. Stephen E. Cone; treasurer, Dr. Magnus A. Tate, and librarian, Dr. Arch I. Carson. At the previous meeting, held February 23, the academy so changed its constitution as to render it the County Medical Society of Hamilton County, to affiliate it with the state and national associations and to allow any non-sectarian practitioner of medicine to become a member.

Societies.

COMING MEETINGS.

AMERICAN MEDICAL ASSOCIATION, FIFTY-FOURTH ANNUAL MEETING, NEW ORLEANS, MAY 5-8.

Florida Medical Association, St. Augustine, April 8.
Western Ophthalmological and Oto-Laryngological Association, Indianapolis, April 9-11.
Tennessee State Medical Society, Nashville, April 14-16.
Medical Association of Georgia, Columbus, April 15.
South Carolina Medical Association, Sumter, April 15-16.
Iowa State Medical Society, Sioux City, April 15-17.
Medical Association of the State of Alabama, Talladega, April 21.
Medical Society of the State of California, Santa Barbara, April 21.
Mississippi State Medical Association, Greenville, April 21-23.
Medical Association of the State of Missouri, Excelsior Springs, April 21-23.
Kentucky State Medical Society, Louisville, April 22-24, 1903.
Texas State Medical Association, San Antonio, April 28.
Louisiana State Medical Society, New Orleans, April 28-30.
Medical and Chirurgical Faculty of Maryland, Baltimore, April 28-30.
Nebraska State Medical Society, Lincoln, April 28-30.
Illinois State Medical Society, Chicago, April 29-May 2.
Arkansas Medical Society, Jonesboro, April 30-May 2.

Placer County (Cal.) Medical Society.—At the annual meeting held at Auburn, February 14, Dr. Charles H. Bulson, Lincoln, was elected president, and Dr. Robert F. Rooney, Auburn, secretary.

Platte County (Neb.) Medical Society.—At its annual meeting in Columbus, February 26, Dr. David T. Martyn, Columbus, was elected president and Dr. Jerome C. McKinley, Humphrey, secretary.

Chattanooga (Tenn.) Medical Society.—At the annual meeting, Dr. William L. Nolen was elected president; Dr. Robert H. Tatum, vice-president; Dr. Joseph W. Johnson, secretary, and Dr. Samuel I. Yarnell, treasurer.

Worth County (Iowa) Medical Society.—At the annual meeting, February 10, at Northwood, Dr. Samuel R. Rice, Northwood, was elected president; Dr. Norman W. Phillips, Manly, vice-president, and Dr. J. Herbert Darey, Northwood, secretary.

Yakima County (Wash.) Medical Society.—On February 24 the society held its annual meeting in North Yakima and elected Dr. B. A. Owens Adair, North Yakima, president; Dr. W. H. Carver, secretary, and Dr. H. R. Wells, North Yakima, treasurer.

Memphis and Shelby County (Tenn.) Medical Society.—At the annual meeting and banquet held in Memphis, March 3, Dr. Bennett G. Henning was elected president; Dr. Edwin Williams, vice-president, and Dr. James L. Barton, secretary, all of Memphis.

Medico-Chirurgical College (Philadelphia) Alumni Association.—At the annual meeting, January 10, in Philadelphia, Dr. George W. Pfromm was elected president; Dr. Stillwell C. Burns, secretary and Dr. Emanuel S. Gans, treasurer, all of Philadelphia.

Tri-County (Neb.) Medical Society.—Physicians of Dixon, Dakota and Thurston counties met at Emerson, February 25, and organized a society, with Dr. James M. O'Connell, Ponca, president; Dr. Charles H. Maxwell, Dakota City, vice-president, and Dr. Robert Q. Rowse, Wakefield, secretary and treasurer.

Franklin County (Ohio) Medical Society.—This society met, February 24, in Columbus, and elected the following officers: President, Dr. Sherman Leech; vice-presidents, Drs. Theodore G. Davidson and James F. Reynolds; treasurer, Dr. John C. Bishop, and secretary, Dr. Charles W. McGavran, all of Columbus.

Western Slope (Colo.) Medical Society.—The physicians of Garfield, Eagle and Pitkin counties, Colorado, met recently at Glenwood and organized the society, with Dr. Leman G. Clark, Glenwood, president; Dr. Wilmer G. Lockard, Newcastle, vice-president; Dr. William W. Crook, Glenwood, treasurer, and Dr. Albert L. Robinson, Glenwood, secretary.

Canadian Medical Association.—The thirty-sixth annual meeting of the association will be held in London, Ont., August 25, 26, 27 and possibly 28, under the presidency of Dr. Walter H. Moorhouse of that city. Dr. Matthew D. Mann, Buffalo, has been asked to deliver the address in gynecology, and Dr. Alexander Hugh Ferguson, Chicago, the address in surgery.

East Jackson County (Mo.) Medical Society.—A local society, made up of the physicians of eastern Jackson County, not including Independence, has been organized at Oak Grove, with the following officers: Dr. Fountain L. Cook, Blue Springs, president; Dr. Elmer E. Perry, Oak Grove, vice-president, and Dr. Noah D. Ravenscraft, Buckner, secretary and treasurer.

Genesee County (N. Y.) Medical Association.—At a meeting of this association, February 27, the following officers were elected: President, Dr. Albert P. Jackson, Oakfield; vice-president, Dr. Henry E. Ganiard, Stafford; secretary and treasurer, Dr. C. Louise Westlake, Le Roy; Fellow to the state association, Dr. William D. Johnson, Batavia, and alternate, Dr. A. F. G. Zurhorst, Oakfield.

Hardin County (Ky.) Medical Society.—The corrected list of the officers elected at the last meeting should read: Dr. Charles Z. Aud, Cecilian, president; Dr. W. H. Shother, Big Spring, vice-president; Dr. James C. Mobley, Elizabethtown, secretary and treasurer; board of censors, Drs. James R. Gray, James W. O'Connor and Frank P. Strickler, Elizabethtown, and delegate to the state society, Dr. Charles Z. Aud.

Tri-State Medical Society of the Carolinas and Virginia.—The fifth annual session of this society was held in Columbia, S. C., February 25 and 26. The following officers were elected: President, Dr. Davis Furman, Greenville, S. C.; vice-presidents, Drs. John H. Marsh, Fayetteville, N. C., William F. Drewry, Petersburg, Va., and Dr. Edward F. Parker, Charleston, S. C., and secretary, Dr. Rolfe E. Hughes, Laurens, S. C. The next session will be held at Danville, Va.

Carroll County (Ky.) Medical Society.—The physicians of the county met at Carrollton, March 9, and, after an address by Dr. Louis Frank, Louisville, councilor for the district, organized a county society, adopted the constitution and by-laws proposed by the American Medical Association, and elected the following officers: President, Dr. Francis H. Gaines, Carrollton;; vice-president, Dr. Percy V. Ellis, Ghent; secretary, Dr. Joseph S. Lehman, Carrollton; treasurer, Dr. J. H. Adcock, Carrollton, and board of censors, Drs. J. P. Wheeler, Prestonville, and W. O. Lindsay and J. Samuel Brown, Ghent.

Associated Health Authorities and Sanitarians of Pennsylvania.—The tenth annual meeting was held in Harrisburg, March 19 and 20. On the evening of March 19 the annual address was delivered by Dr. Lawrence F. Flick, on "The Duty of Boards of Health in the Prevention of Tuberculosis." The relation of boards of health to municipal councils, the working of the law authorizing boards of school directors to enforce sanitary laws of the state, the prevalence of smallpox, and the responsibility of boards of health for the prevention of consumption were among the subjects considered

NORTH BRANCH PHILADELPHIA COUNTY MEDICAL SOCIETY.

Regular Meeting, held Feb. 8, 1903.

The President, Dr. H. Brooker Mills, in the Chair.

Headrest for Removal of Brain.

DR. ADDINELL HEWSON gave "An Exhibit of Dr. B. Stroud's Headrest for Removal of the Brain, Together with Remarks on Such Removal in a Private House." The instrument consisted of a horizontal flat piece of oak and an upright piece in which the head rests and is secured in place by two jaws, which clamps the head just above the mastoid process, thus holding the head absolutely horizontal and firm, the clamps being adjusted by means of thumb screws. With this instrument it is possible to remove the brain and the entire dura from the base of the skull, the dura being very easily removed in the case of a fresh body, while, of course, if the body has been dead for some time, very often the embalming fluids interfere with its removal, those containing zinc particularly having this effect.

DRS. T. TURNER THOMAS and JUDSON DALAND felt that the instrument would be particularly valuable for autopsies in private houses, and for very accurate work in medicolegal cases and where there is cerebrospinal disease.

The Diagnosis and Treatment of Bronchopneumonia.

DR. JUDSON DALAND read this paper and called attention to the fact that the disease has become very prevalent in the past ten years, occurring principally from November to March. There are a variety of causes, such as irritating gases, iron dust, silica and similar irritants, and in many of the constitutional infectious diseases bronchopneumonia is not an uncommon complication or sequela. Bronchopneumonia following influenza is prevalent during the winter, in which there occurs an inflammation of the bronchial tubes and alveoli, which is largely leucocytic, may involve only a few lobules or may involve many lobules in the same region, and not infrequently extends to both lungs. This is one of the peculiarities of bronchopneumonia and is more interesting because it bears on the question of diagnosis. The case may be of the most trifling character in the beginning and yet develop into bronchial pneumonia. The micro-organisms are usually the staphylococcus and streptococcus.

The author felt in the majority of cases the affection began primarily in bronchitis and later the alveoli became affected, mastoiditis also being a not uncommon complication. Thus this swelling of the bronchial tubes interferes with the passage of air through the lungs, and in the course of time produces a considerable area of collapse, which is very difficult to distinguish from bronchopneumonia, and also in association with these other conditions there is frequently spasm of the bronchial tubes. The author also believed that in certain cases of influenza there was an affection of the nerves that have to do with respiration, by which breathing is interfered with without mechanical obstruction. The author felt that, speaking broadly, it was practically impossible to clearly diagnose bronchopneumonia from the symptoms alone, excepting in those cases where the lobules invaded are so numerous that we have a condition analogous to that found in lobar pneumonia. The most important factors, therefore, in the diagnosis are physical examination and an examination of the sputum. In bronchopneumonia following influenza the area of dulness is usually found below the inferior angle of the scapula. The dulness may occur in either or both lungs and may involve the posterior-inferior lobes. In true lobar pneumonia it is impossible to diagnose the affection by the symptomatology or the physical signs, and the inference that it exists may be confirmed by the discovery of diplococci. Reference was made to the frequency with which the signs in this condition shift; an area of dulness being outlined one day, and on the occasion of the next visit the same area would probably be resonant on percussion, but the author felt this should be viewed rather as a corroboration than a doubt of the diagnosis. Attention was directed to the fact that too much stress in diagnosis should not be laid on the presence or absence of bronchial breathing, as frequently owing to the fact that the lungs are not completely areated, breath sounds may be either absent or very much diminished, even where there is resonance on percussion. In the treatment of these conditions, absolute cleanliness of the bronchial cavities and naso-pharynx by the use of boric acid solutions was recommended. In order to render the secretions less acid, and also to stimulate the action of the glands the use of one liter of imported vichy, daily, or when it can not be obtained a watery solution of bicarbonate of sodium, one to two teaspoonfuls to the pint of water, was recommended. Iodid of sodium and of strontium were thought to be the best drugs, the former being best employed in the form of a saturated solution, beginning with 2 or 3 drops four times a day and increasing one drop a day until the dose reached five to ten drops four times a day. Most cases are benefited by 20 to 40 drops of the tincture of nux vomica and 1/20 to 1/30 of a grain of nitrate of strychnia at four-hour intervals. In cases where the cough is particularly distressing, 1/24 of a grain of heroin or ⅛ of a grain of codein was recommended. Forced breathing at intervals of four hours was recommended in order to more thoroughly clean out the bronchial tubes of their contents, to secure complete oxygenation and to secure complete inflation of the lungs. Attention was also directed to the importance of absolute rest, stimulation and good food, during the progress of the disease.

DISCUSSION.

DR. JAMES H. MCKEE referred to the difficulty experienced in differentiating between broncho-pneumonias following influenza and some typhoid pneumonias, and reported a case to illustrate. It began with an initiative chill, followed by high fever and a very irregular temperature, and presented all the physical signs of bronchopneumonia. On the 10th day it proved to be typhoid.

The subdivision of the bronchopneumonias, as made by Holt, was thought to be of great value, particularly with reference to the bronchopneumonias in children, as the acute congestive form would often prove fatal in these cases before any consolidation could be detected in the lungs. The speaker felt the symptomatology to be particularly deceiving in cases of bronchopneumonia following influenza, which is usually characterized by great fluctuations in the temperature, pulse and respiration. Among the most valuable physical signs were mentioned tympany and impaired breathing at the base of the lungs. Treatment of a simple character, and directed more to keeping up the vitality of the patient than to the modification of the course of the disease was recommended.

DR. SAMUEL WOLFE felt that more often was it necessary to make a diagnosis from negative than positive signs, and that diminished respiratory sounds at the bases of the lungs should always excite suspicion of this condition. While bronchial breathing was considered an ideal symptom, if present, he felt that it would be found only in rare cases.

In regard to treatment he did not approve of the deep breathing exercises in the cases where inflammation had already set in, believing that better results would be obtained by frequently changing the position of the patient, thus allowing the infected portion of the lung to keep areation properly and avoid the injurious effects of gravitation. Where the inflammation had not already developed, he felt that these forced breathing exercises might be of value in aborting the pneumonia.

DR. HOWARD S. KINNE felt that forced breathing was inadvisable, as he believed that the lungs should be kept at rest as much as possible when there is acute inflammation. Bronchopneumonia, he stated, occurred more commonly in children, while lobar pneumonia is usually found in adults.

DR. JOHN B. TURNER felt that it was a great mistake to regard the pneumonia as being confined to the lungs entirely, as he believed it was a general disease. The importance of observation for sometime after recovery in order to prevent such sequelæ as phthisis was commented on.

DR. JUDSON DALAND stated that he had never been able to conclusively demonstrate to his own satisfaction bronchopneumonia in the adult. The change of the position of the patient is of value in many instances. Forced breathing,

he thought, would act as a preventive in many instances; and any harm that might result would be more than counterbalanced by the good done to the lung.

La grippe and pneumonia render the individual more susceptible to phthisis, and, in many instances, there is, primarily, a small latent tubercular area, which, under the influence of some such disease as influenza, will become constitutional, thus calling for careful after-treatment. Cotton jackets and poultices seem to be very little used to-day with adults. Moist air is one of the most valuable therapeutic agents in these conditions, and can generally be obtained by keeping the air in the room moist.

In cases where there has been a constitutional disease and pulmonary manifestations, the neurotic element soon arises and becomes prominent. Collapse of the lung following pneumonia was thought to be frequent.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Acne.

Dr. D. W. Montgomery, in *Jour. of Cutaneous Diseases*, states that sulphur is without question our most valuable single agent in the treatment of most cases of acne. He recommends the following combinations:

℞.	Sulph. precip.	3iss	6
	Spts. etheris	3vi	25
	Alcoholis	ʒiiiss	105
M.	Sig.: Apply locally; or:		
℞.	Potassii sulphuret.		
	Zinci sulph., āā	3i	4
	Aquæ rosæ	ʒiv	120
M.	Sig.: Apply locally; or:		
℞.	Sulph. precip.	gr. xx-xl	1.20-2 | 65
	Vaselini	ʒi	30
M.	Sig.: Apply locally; or:		
℞.	Sulph. precip.	gr. xl	2 | 65
	Spts. camphoræ	3ss	2
	Liquoris calcis	ʒiv	120
M.	Sig.: Apply locally; or:		
℞.	Sulph. precip.	3ii	8
	Etheris	3iii	12
	Tinct. camph.	ʒss	15
	Spts. myrciæ	ʒiii	90
M.	Sig.: As a local application.		

Dr. Sherwell recommends the following locally:

℞.	Potass. sulphuret.		
	Zinci sulph., āā	3i	4
	Alcoholis		
	Aq. camphoræ, āā	ʒi	30
	Aq. rosæ	ʒii	60
M.	Sig.: Apply locally.		

Internally he recommends the following on account of its beneficial effect on the pelvic viscera and on lithemic conditions which are commonly present in lithemic individuals:

℞.	Quininæ sulph.	gr. xxv	1 | 65
	Mag. sulph.	ʒi	30
	Acidi sulph. dil.	3ii	8
	Tinct. nucis vom.	3ss	2
	Vini colchici		
	Ext. ergotæ flu., āā	3iii-iv	12-15
	Glycerini		
	Aq. destil., āā, q. s. ad	ʒiv	120
M.	Sig.: One dessertspoonful in water in the morning on rising and one-half that amount at bedtime.		

F. H. Beadles, in *Indian Med. Record*, states that the cause of the acne must be discovered if possible and treated. Improvement follows the reduction of meats, while a diet of milk, fruit, fish, etc., will improve most cases. The entire surface of the body, except the face, should be sponged with cold water and followed by brisk rubbing with a coarse towel.

He claims that arsenic is both useless and harmful, as well as calcium sulphid. In treating the face after rendering it aseptic, a masseeing ball should be rolled freely over the surface and the inconspicuous comedones are brought into view and removed by an extractor. A ring curette may be drawn over the surface of the lesions and their contents extracted.

Bleeding may be encouraged by hot water and the face bathed thoroughly for ten minutes before retiring with tincture of green soap and hot water. It is then wiped dry and the following applied:

℞.	Zinci sulph.		
	Potass. sulphuret., āā	3i	4
	Aquæ rosæ q. s. ad	ʒiv	120
M.	Sig.: To be applied locally at night.		

Tape Worm.

Steinbach, in *Med. World*, recommends the following in the treatment of tape worm:

℞.	Oleoresinæ aspidii	3iss	6
	Olei ricini	3iv	16
	Pulv. acaciæ		
	Sach. albi, āā	3ii	8
	Extracti kamalæ	3iss	6
	Aq. menth. pip. q. s. ad	ʒii	60
M.	Sig.: Take in the morning after twenty-four hours' fasting.		

Dr. D. R. Brower recommends the following combination:

℞.	Oleores. aspidii	m. xl	2 | 65
	Olei terebinthinæ	m. xx	1 | 30
	Spts. chloroformi	m. xx	1 | 30
	Mucil. acaciæ	3ii	8
M.	Sig.: At one dose. The patient should be instructed to fast twenty-four hours previous to taking the teniafuge and to take a strong cathartic three or four hours after taking it.		

Shoemaker advises the following combination:

℞.	Oleoresinæ aspidii	3ss	2
	Olei peponis expressi	ʒss	15
	Olei terebinthinæ	m. xxx	2
M.	Sig.: At one dose, after fasting, to be followed by a purgative.		

Acute Coryza.

The treatment of acute coryza or acute nasal catarrh should be considered from a standpoint of prophylactic, general and local treatment, according to Yeo, in *Clin. Therapeutics*. As prophylactic measures a removal or diminution of hypersensitiveness of the skin and mucous membranes. The use of the cold shower bath throughout the year or cold water applied to the head and neck on rising in the morning, thus counteracting the tendency to vascular asthenia.

Residence in a dry climate is certainly advisable. Sea bathing and sea air are of great value, especially in the chronic forms of nasal catarrh.

The author regards diaphoretics as of most benefit. Opium combined with diaphoretics is preferable and will relieve the most distressing symptoms, as follows:

℞.	Liq. opii sed.	m. x-xv	.65-1 | 30
	Vini ipecac.	m. v	
	Spts. etheris nitrosi	3i	4
	Liq. am. acetat.	3iii	12
	Aq. camphoræ q. s. ad	ʒiss	45
M.	Ft. haustus. Sig.: To be taken at bedtime.		

When opium and morphin are not well borne in small doses even, the following combination is recommended:

℞.	Spts. etheris nitrosi	3iv	15
	Liq. ammon. acet.	ʒii	60
	Potass. bicarb.	gr. xl	2 | 65
	Vini ipecac.	m. xl	2 | 65
	Aquæ camphoræ q. s. ad.	ʒviii	240
M.	Ft. mistura. Sig.: One or two tablespoonfuls every four or five hours. For children the foregoing is well adapted, given in doses of two teaspoonfuls. A combination of camphor with small doses of morphin is well borne:		
℞.	Liq. morph. acet.	m. xv	1
	Spts. camphoræ	m. x	| 65
	mucilaginis	3i	4
	Aquæ q. s. ad.	ʒiss	45
M.	Sig.: To be taken at one dose at bedtime.		

Quinin should as a rule be given after the first twenty-four hours and sooner when there is a marked fever and a feeling of depression. It is best given according to the author in an effervescing saline mixture, as follows:

℞.	Potass. bicarb.		
	Sodii bicarb., āā	3i	4
	Ammon. carb.	3ss	2
	Syr. aurantii	℥ss	15
	Aquæ q. s. ad.....	℥viii	240
M.			
℞.	Quin. sulph.	gr. xii	75
	Pulv. acidi citrici	3ii	8
	Sacch. lactis	3i	4

M. Ft. chart. No. vi. Sig.: One powder dissolved in water and mixed with one and a half ounces of the mixture and taken three times a day.

When there is much aching and general discomfort in the limbs and other parts of the body the following containing salicin is recommended:

℞.	Salicin	gr. xv	1
	Potass. bicarb.	gr. xx	1 20
	Spts. etheris nit.	3ss	2
	Liq. ammon. acet.	3iii	12
	Aq. camphoræ q. s. ad.....	℥iss	45

M. Sig.: At one dose to be taken at bedtime.

In young children, if the throat is also involved, aconite in small doses gives the best results.

When belladonna is indicated the following combination serves the purpose:

℞.	Tinct. belladonnæ	m. xl	2 65
	Potassii chloratis	gr. xl	2 65
	Syr. limonis	3iii	12
	Aquæ q. s. ad.....	℥ii	60

M. Ft. mistura. Sig.: Two teaspoonfuls to be taken every hour until relieved.

For local treatment, the following combination is recommended:

℞.	Liq. am. fortioris	3i	4
	Spts. vini rect.	3ii	8
	Acidi carbol	3i	4
	Aquæ	3ii	8

M. Sig.: Drop this mixture on some absorbent substance and inhale the vapor. The following is also of service in the earliest stage of nasal catarrh:

℞.	Pinol	3ii	8
	Camphoræ	gr. xl	2 65
	Liq. am. fort.	3i	4
	Spts. rect.	℥i	30

M. Ft. inhalatio.

As a powder to be insufflated the following:

℞.	Aluminis pulv.		
	Sodii boratis, āā	3ss	2
	Menthol	gr. 1/3	02
	Zinci tannatis		
	Bismuthi tannatis, āā	gr. xlv	2 65
	Lycopodii	3ii	8
M.	Sig.: To be insufflated into the nares; or:		
℞.	Zinci salicylatis		
	Bismuthi tannatis, āā	3i	4
	Pulv. boraci	3ss	2
	Salol	gr. xx	1 30
	Talci	3ii	8

M. Sig.: As an insufflation into the nares.

Medicolegal.

Who Liable for Medical Attendance on Minor.—The case of Leach vs. Williams, as it is entitled in the Appellate Court of Indiana, Division No. 2, was brought by the latter party against the former, as guardian of a minor, to recover for medical services rendered the minor. The record was silent as to how and for what purpose the party sued was acting as guardian. The evidence also failed to show that the minor had any estate in the hands of the guardian. On the other hand, it showed that the guardian did not have any control or custody of the person of the minor, and did not, in any manner, contribute to his support. The minor was about 17 years old, and had always made his home with his parents, who furnished him with all the necessaries and comforts of life. Moreover, it appeared that the services sued for were procured by the authority of the father of the minor, and that the guardian sued knew nothing of it. It was also clear that the services were rendered on the credit of the father, for the account was originally charged to him, and the account rendered to him. Beside, the physician recognized the liability of the father by asking him, when he rendered his bill, to render an account he had against the physician, so that they might have a settlement, which some personal difficulties between them prevented them reaching. Under these circumstances, the physician obtained a judgment against the guardian in the Circuit Court, which is now reversed by the Appellate Court, which declares the evidence wholly insufficient to support the judgment. A father, the Appellate Court says, is chargeable with the care, support and maintenance of his minor child. It has been held that where a minor child lives in the family of a relative, and the father is alive and able to support it, the guardian of the child, in the absence of any contract on his part, can not be made liable for its support. The maintenance and care of a minor child include necessary medical attendance.

Employment of Surgeon to Attend Injured Servant.—In Lithgow Manufacturing Company vs. Samuel, the Court of Appeals of Kentucky affirms a judgment in favor of the latter party, a surgeon, who brought the action to recover for services rendered to one of the company's employes, who had been seriously injured in an accident in its foundry. The issue was made as to whether the surgeon had been employed by any one authorized to represent the company in that matter. The question was submitted to the jury. A number of witnesses was heard, and, the court says, while the evidence was not as clear and conclusive as was desirable, yet it presented about such a state of case as might not unreasonably be expected, under the circumstances attending a sudden and horrible accident, endangering, probably, the life of one to whom the corporation owed certain peculiar duties as master. At such a time it is not expected that parties should stop to negotiate a formal contract. Here there was evidence to the effect that the company's superintendent and general manager authorized the employment of the surgeon, and that, subsequently, with full knowledge of the fact that he had rendered the services to the injured man, and was continuing to do so, and was expected to continue, he ratified that employment. It was true, that was denied by the superintendent on the trial. Under these circumstances, the court holds that it was one of the cases that was peculiarly in the province of the jury to decide. Continuing, the court says that it still adheres to the doctrine that an unauthorized employment of a physician or surgeon to wait on an injured servant can not bind the master for payment of the surgeon's services, although the master may have been aware that the surgeon was rendering the services. In such case, ordinarily, the court says, the master is not bound to employ a surgeon to wait on one in his employment who may be injured while engaged in his work. However, if the cause of the injury is such that the master would be liable to the servant for damages, including medical bills, because of the master's negligence in any particular, and where the master recognizes this liability and does employ medical attention, or ratifies the employment made in his name, with full knowledge of the fact that it has been so made, the court perceives no sound reason why he should not pay for them.

Negligence of Surgeon of Mutual Benefit Hospital.—The California case of Brown vs. La Societe Francaise De Bienfaisance Mutuelle was brought to recover damages alleged to have been suffered by the party suing, while an inmate of the society's hospital, from the negligent and unskilful conduct of its surgeon in setting his fractured leg. The trial resulted in a judgment for $1,550, which is affirmed by the Supreme Court of California. On the appeal no question was made by the society as to the sufficiency of the evidence to

justify the verdict as to amount, or as to the negligence of the surgeon, but the sole question was as to the liability of the society therefor. The party suing was admitted to the society's hospital for surgical treatment on the terms of paying for the operation, $50, and for a separate room, if occupied by him, $3, or, if occupying the general ward, $2 per day. The operation was performed by the surgeon in chief of the society, who was paid by the month; the amounts received from the party suing going to the society. From this statement, it is said, it was clear that the contract of the party suing was with the society, and that the surgeon was merely its servant or agent. The society, therefore, unless excepted from the general rule of respondent superior (the superior or master must answer), was liable for his negligence. But the contention of the society was that it was a charitable institution, and that, as such, in the absence of allegation or proof of negligence in their selection, it was not liable for the negligence of its servants. In support of the legal proposition thus presented numerous authorities were cited, and, it is said that, though the proposition is not altogether undisputable, either on principle or authority, it might, for the purposes of the decision, be assumed to be correct. As to the remaining question, as to the alleged charitable character of the society, it appeared, from its by-laws, dated May 10, 1854, that it was originally organized as a voluntary association, but was afterwards incorporated by the filing of a certificate of election of trustees June 7, 1854, and on May 5, 1895, new by-laws were adopted. From these it appeared that "the society is established on the basis of mutuality for the treatment of sick members," or, as more specifically provided, for the purpose of securing to its members (without payment otherwise than of dues), medical and surgical treatment, including the services of its physicians, surgeons, apothecaries, dentists, nurses, etc., and also medicines. Nor was there found in it any provision for assistance to others except to paying patients, or sick persons, not members, admitted to treatment for agreed compensation. It was, therefore, it is held, merely an association for mutual profit or benefit, similar in its essential nature to other societies formed for such purposes. Assuming that it was within the powers of the society to adopt the new by-laws, the original by-laws must be regarded as superseded by the latter and, therefore, as immaterial to the question involved, which was as to the present character of the society, though it is stated that the conclusion would be in no way affected were the society still operating under its original by-laws. These, indeed, permitted, and even contemplated, the exercise of charity as one of the aims of the society; but there was nothing in them requiring the application of the funds of the society to such purposes; nor could the funds contributed by the members be regarded otherwise than as, beneficially, their own property. A contention that the surgeon was a sub-agent, appointed by the society as agent of the party suing and, therefore, the agent of the latter, is declared to be without merit.

Current Medical Literature.

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

Philadelphia Medical Journal.

March 7.

1 *Tropical Diseases. Charles F. Kieffer.
2 *The Ductless Glands as Organs of the First Importance in Vital Functions, and Their Relationship as Such to Disease and Therapeutics. Charles E. de M. Sajous.
3 *Gangrenous Destruction of the Pituitary Body, with Disintegration of the Blood, following a Fracture of the Sphenoid Bone and Subsequent Infection. Eugene Wasdin.
4 *Surgical Affections of the Biliary Tracts. John B. Deaver.

1. **Tropical Diseases.**—The points noticed in this lecture by Kieffer are the parasites, *Trichuris trichuria (Tricocephalus dispar)*, which seems to be very common, though not ordinarily producing serious symptoms; ascaris, which is much more common in the tropics than in the temperate regions, and gives rise to considerable trouble there as here. The main part of his lecture, however, is on the distribution and the symptoms of uncinariasis, diagnosed by ova in the feces. He cautions against using solvents of thymol after giving this drug, as fatal cases of poisoning have occurred. Alcohol, ether, glycerin and most oils act as solvents and should be avoided. Castor oil is a purgative which should be avoided in these cases and saline purges used instead.

2. **Ductless Glands and Their Importance.**—This article by Sajous is one which has received considerable attention in the newspapers. He thinks the adrenals have a most important vital function in blood oxidation and that the anterior pituitary body governs their function, they being connected through the sympathetic system. All general symptoms witnessed in disorders in which the blood is invaded by a poison of any kind are, in reality, manifestations of overactivity insufficiency or inactivity of the adrenals. The thyroid gland is also functionally interdependent with the pituitary bodies and adrenals. Together they constitute what he calls the "adrenal system." The organic compound or oxidizing substance which forms in the lungs from loose combination of the internal secretion of the adrenals with oxygen, he calls adrenoxin. A considerable portion of his paper is given up to the discussion of the functions of the leucocytes, which he finds are chiefly active in this oxygenation of the blood, the red corpuscles simply being carriers. The general conclusions as to leucocytes are given in the following:

1. Neutrophile leukocytes form:
Peptones, which combine with adrenoxin to sustain general metabolism, i. e., the vital process.
Myosinogen, which combines with adrenoxin to supply contractile energy to muscles.
Fibrinogen, which combines with adrenoxin to supply heat energy to the blood.
2. Eosinophile leukocytes form:
Hemoglobin, which loosely combines with adrenoxin to insure its storage in erythrocytes.
3. Basophile leukocytes form:
Myelin, the active principle of which, lecithin, combines with adrenoxin to develop nervous energy.

He also has a theory as to pancreatic secretion and the action of the posterior pituitary body as the general center of the nervous system governing metabolism. The latter part of his article is given up to the application of these principles to the pathology of certain diseases, fevers, tuberculosis, etc.

3. **Gangrene of the Pituitary Body.**—Wasdin reports a case in which, after fracture of the inferior maxilla, there were severe general symptoms of jaundice, high temperature, blood disintegration, etc. On autopsy it was found that the trouble was confined largely to the base of the brain, particularly to the contents of the sella turcica, the pituitary body. He was unable to diagnose the condition during life, and discusses it in relation to Dr. Sajous' theories. He says the acceptance of the influence of this hitherto obscure ductless gland, through the cervico-sympathetic system, on the secretion of the more well-known adrenal glands, and of the value of the adrenal secretion in the preservation of the intergrity of the blood, readily explains the puzzling facts in this case without the necessity of seeking the source of a sufficiently virulent toxin to have caused them.

4. **Surgical Affections of the Biliary Tracts.**—Deaver reviews the various surgical disorders of the biliary tracts, calculus, chronic catarrh, etc., of the gall bladder.

Medical Record, New York.

March 7.

5 *Radio-praxis. Henry G. Piffard.
6 *Feeding in Early Infancy—Home Modification of Milk. Joseph E. Winters.
7 *Plastic Artificial Vitreous in Mules' Operation. E. L. Oatman.
8 *Clinical Results with Antistreptococcus Serum in Scarlet Fever. Louis Fischer.

5. **Radio-Praxis.**—Piffard first calls attention to the fact that he, twenty-five years ago, employed sunlight for therapeutic purposes, using the whole spectrum, in other words, simply burning out the lesions. He then notices the history of the Finsen treatment and the Roentgen discovery, and points out the differences between the *x*-ray and ultra-violet rays and describes the apparatus used, especially for the latter. He is inclined to think that much of the good effects reported of the *x*-rays on malignant tumors can be just as well, if not better, accomplished by curettage, incision, actual cautery,

caustics, etc. There are many cases where surgeons will hesitate to use the knife, and with these the *x*-ray apparatus should be tried. The action of blue-violet rays on tuberculosis seems to be a genuine one, according to Piffard's observations. A number of points still needing further elucidation as regards the action of ultra-violet rays on cutaneous disorders are as to whether they are as effective as the *x*-rays; the tension that is required for generating them; the relative value of a spark from a coil or static machine, etc. In conclusion, he notices, particularly, the effects of radioactive substances, such as pitchblende, which seems to have many of the bad effects of the *x*-rays, though it is by no means certain that they are exclusively of this character.

6. **Infant Feeding.**—Winter's article is a lengthy one. He insists on the importance of nursing early in the infant's life, both for the mother and the child, but holds it manifest that the protraction of lactation to eight to ten months is not according to nature. The poorer classes, he thinks, should not be counseled to wean at the end of the second month for economic reasons, owing to the difficulty of securing pure, fresh, sweet milk, but, even with them, nursing should not be extended beyond five to six months. A child born in the spring should be weaned in the autumn, and one born in the autumn should be weaned before the summer. He gives directions as to the preparation of milk as a substitute for mother's milk, and a full series of formulas for each period in the infant's life up to the end of the year, and also the home modification of bottled milk during the summer months.

7. **Paraffin in Ophthalmic Operations.**—Oatman describes the method of using paraffin employed by him in a case to make a proper stump after Mules' operation. He offers the following as his "immature" conclusions from three cases in his experience:

When fistula follows the Mules' operation it will close spontaneously if a sufficient quantity of the artificial vitreous can be removed. That which remains will form a good support for an artificial eye.

Paraffin used for this purpose is prone to produce fistula by softening and getting between the lips of the wound, or into the track of a suture. These accidents are to be avoided by using paraffin, or some modification thereof, that will not soften at body temperature; also by so suturing the scleral wound that no aperture remains through which paraffin can exude.

A plastic material like paraffin will adapt itself to any inequalities on the surface of the glass shell, and ulceration from pressure is not apt to occur.

Paraffin beads are easily prepared, and may be used in special cases in which glass beads of the required shape or size are not obtainable.

8. **Anti-Streptococcic Serum.**—Fischer gives the results of his observations of the Baginsky method of treating scarlet fever, reporting two cases. He thinks it is too soon to formulate definite conclusions based on such limited experience, but the clinical results were striking. The effect of the serum on the temperature shows that it did inhibit bacterial products and the disappearance—almost melting away—of necrotic membranes after the fourth day is another striking fact. The swollen glands of the neck also subsided. A vital point consisted in a strengthening diet in addition to strict hygiene.

Medical News, New York.

March 7.

9 *Periduodenal Abscess Secondary to Ulcer of the Duodenum. William S. Bainbridge.
10 Mosquito Extermination in New York City. George A. Soper.
11 Some Practical Suggestions on Mosquito Extermination in New Jersey. Henry C. Weeks.
12 The Sanitary Aspect of the Mosquito Question. John B. Smith.
13 *The Symptomatology of Tabes: An Analysis of 140 Cases of Locomotor Ataxia. Joseph Collins.

9. **Periduodenal Abscess.**—Bainbridge reports a case and gives an epitome of the literature of this rather rare condition. He finds that altogether, including the case here reported, twenty-six are on record; twenty-two died undiagnosed; in two operation was performed, and in one a cure was obtained. The duodenum, though a deeply seated and fixed organ, is really in greater danger in its close relationship to the spine and right kidney than some others more superficially placed. He shows from the anatomy of the parts how an ulcer perforating the walls may give rise to simulation of appendicitis by following down the ascending colon. The most frequent symptoms are vomiting, pain, tenderness and resistance in the epigastric and right hypochondriac regions, constipation or obstipation, and sudden onset or shock. Melena or hematemesis are not common. There is little elevation of temperature unless complications arise, such as peritonitis, pleurisy, cholecystitis, stomach perforation, etc. It occurs most frequently in the male. The following should be specially thought of in connection with this disease, empyema, pleurisy with effusion, cancer of the pylorus, of the liver, pyopneumothorax, hydatid cyst, liver abscess, intestinal obstruction, gall-bladder disease and appendicitis, the latter being the most frequent condition simulated. The diagnosis is always difficult. Leucocytosis may be of some value. If there has been an indication of ulcer, like pain in the stomach two to six hours after eating, tenderness to the right of the twelfth dorsal vertebra, vomiting, especially of blood, and if sudden severe pain with increasing vomiting and collapse appear, operation is imperative.

13. **Tabes.**—Collins describes the various types, including the neuralgic, the sympathetic nervous type with vesical symptoms, crises, and arthropathies, the type in which optic atrophy develops early, cervical or high tabes, the slow appearing and the rapid appearing type. He is not quite sure whether a cerebral type should be included, not paresis, and is inclined to think that it should be. Illustrations are given of each of these, and an analysis of the initial symptoms in 126 cases. Pain was not so frequent as generally supposed by other observers, though it occurred in about 40 per cent. of the cases, and during the course of the disease in about 90 per cent. Paresthesia is one of the commonest symptoms, nearly as constant as pain, and present in 73 per cent.; girdle sensation in 30 per cent., or 45 per cent. altogether. Tactile sensory disturbances appeared in about 67 per cent.

American Medicine, Philadelphia.

March 7.

14 *The Technic of the Operation of Celiotomy as Practiced at the Gynecean Hospital, with the Report of 93 Consecutive Celiotomies without a Death. Henry D. Beyea.
15 *The Treatment of Suppurative Inflammation of the Kidneys. Frank Warner.
16 *Direct Fixation in Fractures. George W. Guthrie.
17 Aneurism of the Descending Aorta Displacing the Heart. Charles F. Beeson.
18 *Communicated Insanity or Psychic Infection. J. W. Wherry.
19 *Briefs on Physical Training. G. Frank Lydston.
20 The Ill Health of Herbert Spencer. George M. Gould.

14. **Celiotomy.**—Beyea describes in full detail the methods employed by the Gynecean Hospital, Philadelphia, and their results in 94 consecutive unselected cases, including hysteromyomectomy, the various operations on the appendages, panhysterectomy, operations for appendicitis, uterine displacements, gastric derangements, tuberculous peritonitis, etc. There was but one death, and that the result of a far advanced sarcoma of the uterine parenchyma involving all tissues to the pelvic bone. In none, regardless of the character of the disease, was there any suppuration of the abdominal incision, or hemorrhage in the tissues or other complication. Intestinal injury was repaired in five cases and recto-abdominal fistula in one. With the one exception all the patients recovered completely.

15. **Kidney Suppuration.**—Warner gives his experience with kidney suppurations, and holds there are many cases in which a very mild grade of pyelitis exists, curable by the timely administration of urinary antiseptics and by a judicious tonic course. The diagnosis is not always clear, but operative treatment is indicated absolutely only in prolonged cases with emaciation, hectic, etc.

16. **Fixation in Fractures.**—Guthrie advocates the direct fastening of fractures, and quotes a limited number of cases where it has been successfully employed. He also reports a case of his own observation of fracture of the olecranon treated under the ordinary home conditions in this manner with success. He does not hesitate about treating cases where operation is imperative, in the homes of the patients, using the commonsense means of disinfecting and sterilizing, including the use of rubber gloves, and not always subjecting the patient to the inconveniences and suffering of rushing them off to the hospital in order to get clean surgery.

18. **Communicated Insanity.**—A number of cases are reported by Wherry where one patient has communicated his or her delusion to another, usually brothers and sisters, though there was one case where it was communicated from husband to wife. He calls attention to the peculiar religious character of the delusions in the cases reported, and thinks it is only a few steps from the ordinary beliefs of religious faith to insane delusions in morbidly constituted individuals. He considers that the factor of heredity is, perhaps, overestimated in these cases.

19. **Physical Training.**—Lydston describes the effect of physical over-strain by myocardial degeneration, renal disease, emphysema, aneurism, general myasthenia and hernia. He speaks of the bad effects of a tight belt, restricting the abdominal muscles at a time when all the other muscles are having full play, and the dangers of alcohol and tobacco to athletes. He would taboo competitive athletics as ordinarily understood, though he admits its impracticability.

New York Medical Journal.

March 7.

21 *Some Scientific and Practical Aspects of Vaccination. P. H. Bryce.
22 *The Present Method of Medical School Inspection in New York. Charles Herrman.
23 *Uterine Inertia: Its Causes and Treatment. James Moran.
24 *Incomplete Transverse Congenital Occlusion of the Vagina, and a Theory as to Its Origin. Samuel M. Brickner.
25 *Expression of the Lid Margin as a Therapeutic Measure in Blepharitis and Its Complications. Percy Fridenberg.
26 The Detection of Renal and Vesical Calculi by Means of the X-Rays. Henry P. Moseley.
27 A Case of Abnormal Temperature. Lucien Lofton.

21. **Vaccination.**—Bryce holds that the official opinion is crystallized into the following conclusions: 1. Either that official supervision of the products of vaccine establishments by either state or federal officers is imperatively demanded; 2, or that the production in state or federal vaccine establishments of adequate supplies of vaccine of established quality, to be sent out free, or at cost, to municipalities, has become a necessity. He remarks that the capital and competition of large commercial houses supply and maintain a standard of excellence which, perhaps, individual states could not reach, but he thinks that public vaccinators should be appointed, whose experience will lead them to accept only standard reliable vaccine material and prevent the accidents which have injured the credit of this prophylactic measure.

22. **School Inspection.**—Herrman describes the methods at New York. There are eighty school inspectors for the Borough of Manhattan, each with 4,000 to 5,000 scholars to inspect. The class rooms are visited and each pupil examined once a week. Lists of pupils who have been absent on account of sickness are obtained; they are visited, and the character of the disease determined. The pupils are taught to use separate pencils and penholders. Children presenting symptoms of a contagious disease are immediately attended to and are visited by the district medical inspector, who advises when they are ready to return to school.

23. **Uterine Inertia.**—The causes of this condition and the dangers to the mother and child are noticed by Moran, who gives the treatment of the various special conditions. If, from excessive uterine distension, the membranes should be punctured and the excess of water allowed to escape, he does not use ergot, but prefers instruments, considering them a less risk in primary inertia. In primary inertia, from rigidity of the cervix, he usually gives chloral and morphin hypodermically, which tends to relax the os and soothe the patient. In some cases he uses local cocain applications. When the os is well dilated, strychnia sulphate 1/40 to 1/30 of a grain hypodermically, repeated in two hours, if necessary, and a little alcoholic stimulation. In secondary uterine inertia, he advises rest, a few hours of sleep, after which the pains will usually return with sufficient frequency and force to complete labor within a reasonable time.

24. **Transverse Occlusion of the Vagina.**—The following are Brickner's conclusions:

1. Transverse septa of the vagina are rare, occurring in about one in 5,000 cases, about .002 per cent.
2. They are derived from an inclusion by Müller's ducts of cells from the Wolffian duct or ducts after the formation of the genital cord, and are, therefore, epiblastic in origin.
3. Their perforation is proof of the normal conduct of Müller's ducts in all other respects.
4. Transverse septa of the vagina, being normal in adult sheep, whales, dugongs, the manatee, and the chimpanzee, they represent in the human being a reversion, "a return to an ancestral type." Their function is purely speculative, but may have to do with the facilitation of conception; and when they appear in the human female may have a similar purpose, in harmony with other minor defects of development.
5. The treatment of this condition is excision of the septum with suturing of the cut edges. In unmarried women no treatment is necessary. If the septum is first seen early in pregnancy, it may be excised; if during labor, a crucial incision will be sufficient, with subsequent removal of the septum. The prognosis for the child is usually bad unless the septum is incised early or unless it is not too strong to be burst by the advancing head; for the mother, it may result in serious lacerations or fatal hemorrhage.

25. **Blepharitis.**—Fridenberg calls attention to the utility of expression of the lid margins in blepharitis as a method of treatment and prophylaxis, and reports cases. He does not think it has a specific action or urge its use to the exclusion or neglect of other methods, but thinks it is a valuable aid that has been too much neglected.

31 *Intestinal Obstruction Below the Ileocecal Junction. (Concluded.) Thomas H. Manley.
32 Symptoms Simulating Appendicitis Caused by an Intra-abdominal Band. James A. Keown.

28. **Blood Pressure.**—Crile considers the conditions of diminished blood pressure, shock and collapse, points out the value of adrenalin in these cases, and summarizes as follows:

In many instances the control of the blood pressure is synonymous with the control of life itself. Surgical shock is an exhaustion of the vaso-motor center. Neither the heart muscle, nor the cardio-inhibitory center, nor the cardio-accelerator center, nor the respiratory center, are other than secondarily involved. Collapse is due to a suspension of the function of the cardiac or of the vaso-motor mechanism. In shock therapeutic doses of strychnin are inert; physiologic doses are dangerous or fatal. If not fatal, increased exhaustion follows. There is no practical distinction to be made between external stimulation of this center, as in injuries and operation, and internal stimulation by vaso-motor stimulants, as by strychnin. Each in sufficient amount produces shock, and each, with equal logic, might be used to treat the shock produced by the other. Stimulants of the vaso-motor center are contraindicated. In shock cardiac stimulants have but a limited range of possible usefulness, and may be injurious. In collapse, stimulants may be useful because the centers are not exhausted.

Saline infusion in shock has a limited range of usefulness. In collapse it may be effective. The blood tolerates but a limited dilution with saline solution. Elimination takes place through the channels of absorption. Its accumulation in the splanchnic area may be sufficient to fix the diaphragm and the movable ribs, causing death by respiratory failure. Saline infusion in shock raises, but can not sustain, the blood pressure.

Adrenalin acts on the heart and blood vessels. It raises the blood pressure in the normal animal; in every degree of shock; when the medulla is cocainized, and in the decapitated animal. It is rapidly oxidized by the solid tissue and by the blood. Its effects are fleeting; it should be given continuously. By this means the circulation of the decapitated dog was maintained ten and one-half hours. In excessive dosage there is a marked stimulation of the vagal mechanism. Due caution must be exercised.

The pneumatic rubber suit provides an artificial peripheral resistance without injurious side effects, and gives a control over the blood pressure within a range of from 25 to 60 mm. mercury. By the combined use of artificial respiration, rhythmic pressure on the thorax and adrenalin injected into the jugular vein, animals which were apparently dead as long as fifteen minutes were resuscitated.

The suit referred to is made of a double layer of specially constructed rubber and, when inflated, gives a uniform pressure on the surface, producing an artificial peripheral resistance, thus preventing "intravenous hemorrhage" in and exhaustion of the vaso-motor center.

29. **The Routine Determination of Arterial Tension.**—The value of blood-pressure observations, especially in conditions of shock and in operative procedures, is insisted on by Cushing. It is especially when the central nervous system is involved in operations that they are of most value. Also in abdominal surgery there is a great field for them owing to the importance of the sphlanchnic vascular territory.

30. **Cyto-Diagnosis.**—The technic of cyto-diagnosis in serum is described, the formulæ, and the methods in various conditions such as pleurisies are noted in detail. A number of cases is also reported. Musgrave says he can state without

hesitation that the descriptions given by Widal and other observers have been accurate so far as his knowledge is concerned. He thinks the procedure will be found of clinical value after more thorough observation and study.

31. **Intestinal Obstruction.**—In this concluding lecture Manley describes the operative treatment, formation of an artificial anus, resection with anastomosis, etc. He notices the dangers of various surgical procedures and the importance of early operation where possible. The male subject is notoriously less tolerant of intraperitoneal exposure and manipulation than the female. Resection with anastomosis is the ideal procedure when the condition of the patient and the character of the lesion justify it. The risk of peritoneal contamination and the need of precision of technic are especially emphasized. In the rectum, cancer and luetic strictures most frequently call for surgical relief. The first and safest method is an enterostomy of the sigmoid above the pubis. This side-tracks the fecal current, and relieves urgent symptoms. The second is sacral resection in the male, or vaginal in the female, both of these contemplating the removal of the growth and rectal anastomosis. The last method involves a laparotomy as well as a section from below, and then drawing the third segment of the sigmoid down into the hiatus as a substitute for the displaced rectum, or after the diseased rectum is removed, establishing a left flank anus by the free, open end of the sigmoid. The difficulties of this operation are mentioned. Some of the operations depicted in the illustrations we meet are not only, he says, impracticable on the living, but impossible on the cadaver. The artist is usually innocent of any knowledge of anatomy or pathology.

44 *The Treatment of the Insane in Private Practice. F. Savary Pearce.

39. **Gunshot Wounds.**—Wagoner reports a case in which a man was shot in the chest and head and it was found that the liver, lungs and stomach were involved. The special point of interest was the similarity of the abdominal wound to that of President McKinley, but it was more severe in that the liver and lungs were perforated and excessive hemorrhage occurred. In spite of embarrassment on account of religious prejudice, etc., and the very extensive operation and the incisions required, the patient recovered. Death seems to have been prevented at the critical point, by transfusion with normal salt solution. The stimulating and sustaining effects of the enemas of black coffee are also noted as of interest.

47. **Uretero-Ureteral Anastomosis.**—Johnston reports a case operated on by a modified Van Hook operation with good success.

48. **Movable Right Kidney and Appendicitis.**—The points emphasized by Manton are: 1. With obscure abdominal conditions, even without discoverable pelvic disorder, a diagnosis should not be attempted until movable kidney and appendicular disease can be excluded by careful abdominal palpation. 2. When nephroptosis and appendicitis are present, operations on the uterus and adnexa alone will not be followed by cure of the patient unless one or both of these conditions have also been removed. The conditions present will govern the question of anchoring the kidney and removal of the appendix together. In movable kidney of the first degree ablation of the appendix alone will generally be all that is necessary. In prolapse of the second degree both operations may be necessary according to the severity of the symptoms, and in the third degree both the appendix and the kidney should receive attention. If the appendicitis is of a mild type and the nephroptosis marked, generally the mere fixing of the kidney to the lumbar wall will, by restoring the circulation in the appendix, cause the latter to resume its normal position or at least will result in a cessation of symptoms.

65 *Dislocation of Individual Carpal Bones, with Report of a Case of Luxation of the Scaphoid and Semilunar. William Hessert.
66 *The Treatment of Infantile Spastic Paralysis. Robert Jones.

54. **Macroglossia Neurofibromatosa.**—The case reported by Abbott and Shattock, though put under the head of macroglossia in which it clinically falls, has nothing in common with the ordinary lymph or hemangiomatous form of the disease, and requires differentiation by such title as here given. The case is carefully reported and the literature briefly discussed.

55. **Actinomycosis.**—Von Baracz finds that actinomycosis is produced solely by the *Streptothrix actinomycotica*. He discredits the theory that the disease enters through decayed teeth. They favor the occurrence, however, by making softened and swollen gums an easy entrance. The fungus rarely develops in the mucous membrane of the mouth itself; it wanders toward the surface of the body, and develops either in the region of the angle of the lower jaw or lower in the neck. The bones are never primarily affected in actinomycosis of the jaws. The central bone forms of Poncet do not exist. His first cases were treated by operation, consisting of curettement and extraction of teeth. By hypodermic injections of irritants like tincture of iodin, and 20 per cent. solutions of silver nitrate, he was able to produce a connective tissue wall around the softening area, and in this manner he was able to cure his last 9 cases without any operative interference. When it attacks the thorax or the lungs the prognosis is unfavorable. In abdominal actinomycosis the fungus always enters the body

through the mucous membrane of the alimentary tract with vegetable bodies, which usually lodge in the region of the cecum or appendix. In these cases the prognosis is good only if the disease is limited; if, however, the prevertebral tissue, liver or the portal veins become involved, it is very bad. Von Baracz considers that only one form of fungus produces this condition. It is easily diagnosed microscopically and may be even possible to diagnose macroscopically with some degree of certainty.

59. **Acute Yellow Atrophy of the Liver.**—Ballin reports a case with favorable outcome and rather favors the theory that the disease is due to the action of chloroform rather than infection, though he points out that in all cases there was an inflammatory condition pre-existing. As a prophylactic he would advise against the prolonged use of chloroform whenever alcohol or some long chronic ailment has caused catarrh of the liver ducts, especially when we have to do with inflammatory visceral conditions. The narcosis may be begun with chloroform, but ether should soon be substituted. In the case of malignant jaundice, the chances are unfavorable. Success in his case he attributes to venesection and subsequent intravenous saline infusion.

60. **Primary Retroperitoneal Solid Tumors.**—The tumor in the case reported by Douglas was a lipomyxoma with a round-celled sarcomatous base, weighing fourteen and one-half pounds. The varieties, etiology, pathology, etc., are discussed. He remarks that the prognosis in the innocent forms is ultimately as grave as in sarcoma, the disturbances from pressure finally bringing about death from marasmus, and the change to malignancy should be considered. Operative results have been in some cases successful as in the one here reported. The contra-indications are pronounced cachexia, metastasis, and manifest universal attachments. After opening the abdomen the condition may be found inoperable. The dangers present, especially in removal of these encapsulated tumors, are hemorrhage and necrosis of the intestine or parietal peritoneum. If the intestinal circulation is impaired, resection of the gut may be required. Drainage must be provided, and is usually best obtained through the loins.

61. **Typhoid Perforation.**—In the one of the three cases here reported by Brown that recovered there was a faint omental agglutination occluding a very recent perforation, and this suggests to him the possibility of intestinal immobilization as advocated by Ochsner, rigorously observed, bringing about a natural instead of a surgical closure of the lesion. He does not wish, however, to be understood as opposing surgical measures, but where it is delayed or absolutely refused, the necessity of using every possible recourse to aid nature.

62. **Hip Injuries in the Aged.**—Allis calls attention to severe symptoms occasionally occurring from very slight falls on the buttocks. He notices the several theories to account for them, such as, 1, osteophytes springing up about the injured joints. He found this condition in one of his patients. 2. Concussion of the joint. 3. The sciatic nerve may be injured. He has no facts, however, to support this last theory nor another one as to tearing of the ligamentum teres. If the pain persists after one or two months, operation may be advisable and is warranted provided the age and strength of the patient permits.

65. **Carpal Dislocation.**—Hessert calls attention to the probably more frequent occurrence of these injuries than has been generally considered, and gives an analysis of the reported cases.

66. **Treatment of Infantile Spastic Paralysis.**—This gives in substance the same general ideas as the article abstracted by us in THE JOURNAL of March 7, p. 677, from the *Lancet*.

77 *Entrance of Air into the Veins—A Reply to Dr. Hare. Malcolm Goodridge.

67. **Carcinoma of the Choroid.**—After a carefully reported case, Oatman discusses the general appearances of this condition, briefly reviewing the principal cases on record. He finds that the literature yields thirty cases which may be considered genuine. It usually occurs early in middle life. The primary growths are mainly in the breast, though other organs may be primarily involved. This excessive incidence of breast cancer is the cause of the greater number of females affected with choroidal carcinoma. The theory that the left eye is the most frequently invaded is not supported by his statistics, and both eyes have been involved in one-third of the cases. The deposit always occurs posteriorly, near the point where a short ciliary artery enters the globe, and appears in the corresponding region of the second eye when the latter is attacked, indicating that the second eye is not invaded by way of the lymph channels of the optic nerve and chiasm. The typical shape is a flat discoid thickening of the choroid with a central elevation, sloping off to the periphery. The eye symptoms rapidly progress until the destruction of vision in two to eight weeks due to the early and extensive retinal detachment. The tension is increased in about one-third of the cases and diminished or normal in over two-thirds. The average duration of life after eye symptoms appear is six and one-half months. He gives in parallel columns the distinctive points between sarcoma and carcinoma. The condition is hopeless. He does not advise operative interference as it may hasten the death.

69. **Banti's Disease.**—Field's article describes a case and discusses the condition, ending with the following conclusions:

1. There are four conditions, more or less closely related, which may be distinguished as follows: Enlargement of the spleen with anemia and the later development of a cirrhotic process in the liver may be separated from cirrhosis of the liver, with secondary enlargement of the spleen, by the fact that in the latter condition the spleen never attains the size that it does in the former. Both these conditions may be separated from splenic anemia and primary splenomegaly by the presence of the cirrhosis of the liver, while these two latter conditions may only be differentiated from one another after a microscopic examination of the spleen.
2. The case here reported should be placed among those cases termed "Banti's disease" for three reasons: (*a*) The very great enlargement of the spleen; (*b*) the presence of a cirrhotic process in the liver; (*c*) the fact that the enlargement of the spleen was due to a general hyperplasia, but more especially of the connective tissue.
3. The present case, exhibiting an advanced chronic productive nephritis, somewhat extends the scope of the pathologic anatomy of Banti's disease. Speculation as to the etiology of the disease seems at present premature, but the increasing recognition of the occurrence of transitional cases connecting together Banti's disease, splenic anemia, and diffuse cirrhosis of the liver suggests an origin from a common cause emanating from the gastrointestinal tract.

70. **Rheumatism.**—Three cases of mild acute rheumatism, one of subacute, one of neuritic affection of the peripheral nerves, together with one of rheumatic arthritis are described by Stengel. He considers the latter disease partly nervous and partly rheumatic. He thinks the history of the cases of this condition indicates deterioration of the nerve force and loss of vitality and is entirely compatible with the theory of primary changes in the nervous system as constituting its pathology. The microbic theory of rheumatism is thought by him not worth serious consideration.

73. **Blood Pressure Determination.**—Cook gives the results of blood pressure determination in sick children and calls attention to the importance of this method as an indication for stimulant treatment. There is no reason, he thinks, why a blood pressure chart should not be kept as well as one for the temperature or pulse where a trained nurse is employed. He does not make it take the place of other signs and symptoms, but simply insists that the accurate estimation of arterial tension furnishes additional aid to stimulant therapy.

74. **Malaria.**—Woldert reports the conditions in Texas favoring malaria. The anopheles are exceedingly numerous and he gives figures showing the financial burden which malaria is on the state. For destroying the larvæ of mosquitoes he finds a strong solution of tobacco and kerosene oil, one pound to ten gallons, most efficient.

75. **Epilepsy and Heart Disease.**—From a careful study of the subject, Chadbourne concludes that there is nothing to show to his satisfaction that there exists a direct connection between the vascular lesions and epilepsy. The administration of digitalis where it seemed indicated, did not apparently have any appreciable effect on the attacks. In no case was there any noteworthy improvement in the condition of the heart and the increasing severity of the heart disease did not seem to affect the attacks. It is, therefore, more than doubtful that the occurrence of heart lesions in epilepsy is anything more than a coincidence. At least the verdict of "not proven" must stand for the present. In senile cases, the evidence from the literature seems a little stronger, but his own observation is not supporting, and for satisfactory proof that the cardiovascular disease is the cause of epilepsy, we must adhere to the postulates of Stintzing: 1. That the heart disease must precede the epilepsy; 2, other causes must be excluded; 3, the coincidence must be frequent; 4, improvement in the heart disease must improve the epilepsy. The first condition is satisfied in many cases as is also the fourth, and a number of cases are recorded, though not in his own series. He does not find the coincidence frequent and the exclusion of other causes seems almost impossible.

76. **Hydatiform Mole.**—Findley summarizes in substance as follows: Nothing is known of the cause. It usually occurs between 20 and 30, and is more than twice as frequent in multiparæ. The weight of evidence is in favor of a maternal origin, and the vesicular degeneration of the chorionic villi resulting from a disturbed maternal circulation. There is no proof that cystic degeneration of the ovary has any influence. It is so common as compared with the latter that it is not likely they stand in relation of cause and effect. Malignant degeneration of hydatiform mole occurs in about 16 per cent. of all cases. No sharp line can be drawn between benign and malignant hydatiform moles and macroscopic and microscopic examination may not determine the character. The length of time the mole remains in the uterus does not influence its disposition to become malignant. The diagnosis can not be made with certainty without seeing the vesicles. They are seldom expelled spontaneously before the abortion is in progress, therefore, diagnosis is rarely established until expulsion. The most common clinical evidence is the rapid uterine development and hemorrhage, also the irregular shape and consistency of the uterus. In view of the tendency of hydatiform mole to undergo malignant degeneration, our only safeguard lies in early recognition and immediate removal, however limited the degeneration may be. Ergot and vaginal packs will control the hemorrhage and often excite the uterus to contract and expel the growth. The curette should not be used for fear of perforation of the overstretched uterine walls. After the mole is expelled always explore the uterus with the finger, irrigate, and pack with antiseptic gauze. Two weeks after expulsion of the mole it is well to curette the uterus and examine the scrapings for syncytial invasion, and if found in the act of proliferating, hysterectomy should be performed. About three years of watchful expectancy should follow the expulsion. In the event of uterine hemorrhage an exploratory curettage should be made for microscopic examination of the scrapings. All new growths in the vagina or lungs should be regarded with suspicion. He gives a detailed summary of the statistics from reports of 210 cases. He finds also that contrary to the usual statement that there is a tendency to development of two or more hydatid moles, it is found to be the great exception.

77. **Entrance of Air into the Veins.**—Goodridge combats Hare's statement as to the innocuousness of the introduction of air into the veins. He holds that the statement that entrance of small quantities of air into the veins need not be a source of anxiety is pernicious teaching and may lead to carelessness.

University of Pennsylvania Medical Bulletin, Philadelphia.

February.

78 *A Report of a Case of Chronic Acetanilid Poisoning, with Marked Alterations in the Blood. Alfred Stengel and C. Y. White.

81 *Traumatic Lesions of the Spinal Cord without Fracture of the Vertebræ. William G. Spiller.
82 Osteopsathyrosis: With the Review of a Case Having Sustained 22 Fractures in a Period of Ten Years. Montgomery H. Biggs.

78. **Chronic Acetanilid Poisoning.**—In the case described by Stengel and White, the patient had been taking for years sometimes as much as 15 or 20 three-grain acetanilid capsules per diem. Before using them she had taken antikamnia and other antipyretic anodynes. The appearance of the case was one of cyanosis due to complete disorganization, and bleeding was first resorted to. The drug habit had been denied, but was elucidated during the progress of the case. There was a very marked anemia with nucleated cells, some of them red corpuscles. It had been diagnosed by a physician as due to an intraventricular cardiac lesion, but the progress of the case proved that no such condition was present. There was a number of separate attacks of cyanosis during the treatment, which were afterwards found to be due to the drug. Pronounced enlargement of the spleen was an interesting feature.

79. **The Blood Pressure.**—Stanton describes the apparatus and methods and gives the history of the subject. He describes a new appliance; a modification of the Riva-Rocci apparatus, which he devised and which is employed in the Pennsylvania University Hospital.

80.—See abstract in THE JOURNAL, xxxix, p. 857.

81. **Spinal Concussion.**—Spiller describes a case without injury to the vertebra or any evidence of mechanical pressure. There was marked disorganization of the cervical cord finally ending in death, though there was marked improvement in the paralysis.

86 *Rheumatoid Arthritis. F. B. Bishop.
87 *Therapeutics of Dry Hot Air. Clarence E. Skinner.
88 A New Combined Electric Arc and Incandescent Radiant Light and Heat Bath. Sigismund Cohn.
89 The Rational Basis of Electricity in Gynecology. G. Betton Massey.

86. **Rheumatoid Arthritis.**—Bishop credits the disease to defective nutrition, too much use of starchy food, etc. He thinks that a properly-regulated diet and electricity, plenty of red meat, etc., are required. He gives illustrations of cases treated by electricity, which he claims increases the local nutritive functions of the joints, skin and muscles and also of the organs of excretion and secretion. The cases he reports seem to have been wonderfully benefited.

87. **Dry Hot Air.**—Skinner concludes that the advantages of dry hot air in local sepsis are: 1. Rapid relief of pain. 2. The induction of hyperleucocytosis, whereby the infective process is frequently abruptly arrested and nearly always prevented from spreading from structure to structure. 3. Relief of the nerve centers to a large extent from toxin depression, because of an increase in the process of elimination. 4. The avoidance of reaction from drug stimulation, because an amount of depression sufficient to demand the same does not

ordinarily obtain after the administration of hot air has been commenced.

96 *Trichloracetic Acid Treatment of Infective Ulcers of the Cornea. Albert E. Bulson, Jr.
97 *Concerning the Disappearance of the Lesions in Circinate Retinitis. G. E. de Schweinitz.

92. **The Salicylates in Eye Diseases.**—Gradle reports his experience with the salicylates in the various forms of eye disease. He finds the salicylates advantageous in that form of apparent episcleritis, which he has elsewhere described as subconjunctival inflammation. He has used them in this as well as other types of episcleritis after other drugs have failed, with decided benefit. They have a striking effect on the minute superficial corneal infiltrates which occur after slight trauma. In the ordinary or syphilitic cases of keratitis, they have not been specially useful, excepting perhaps in the diffuse keratitis of scrofulous children or in gouty subjects. He gives an account of a case of nodular sclero-keratitis in which they were used with decided benefit. In the ordinary typical iritis they have been disappointing, and he has had only negative results in typical cyclitis. But in the atypical forms of uncertain duration and usually of protracted course, they have been almost specific. Other conditions in which he has found them of benefit are the sympathetic inflammations and the rare cases of non-traumatic and non-suppurative tenonitis. He has not seen much benefit in what has been called uveitis or acute inflammation of the retina or of the optic nerve. But in the chronic uveitis, of indefinite duration, they have a marked control over the intensity of the symptoms. He agrees with Gifford in the necessity for large doses. An adult requires 20 grains of sodium salicylate at least four to five times a day, while if 25 grains can be tolerated 5 to 6 times or even oftener a day, the quicker the results obtained, but when such large doses have no effect within forty-eight to sixty hours, it is no use continuing. By using 5-gr. tablets, coated over as desired, the stomach irritation is avoided. The limit to its use is generally indicated by tinnitus or a feeling of confusion.

95. **Congenital Ocular Anomalies.**—Posey reports two cases, mother and daughter, both possessing colobomatous appearing conditions suggesting imperfect closure in the fetal cleft.

96. **Trichloracetic Acid in Corneal Ulcer.**—Two cases thus treated are reported by Bulson. His experience leads him to believe that in purulent ulcer of the cornea no matter what the character of the infection, treatment with trichloracetic acid is superior to pure carbolic acid or any other caustic with which he is familiar and much safer than cautery or galvanocautery and more efficient than curettage.

97. **Circinate Retinitis.**—Three cases are briefly reported by de Schweinitz, in all three of which the white bodies of circinate retinitis had more or less disappeared. He discusses the condition and says the conclusion is that given a case of this type, a fatal prognosis as regards vision should not be immediately given and all reasonable therapeutic measures given a fair trial. It may be, he says, that the disease has not been long enough persistent or pronounced to bring about destruction of the areas involved or it may be that Gunn's explanation that the zone of white is a manifestation of long-standing edema is correct. He has some faith in the iodids in these cases, especially the iodid of sodium. Mercury bichlorid seems useful. He would also try subconjunctival saline injections and perhaps pilocarpin diaphoresis.

2. Action of Secretine on Liver.—Secretine is the fluid obtained by acid maceration of the mucosa of the duodenum of a fasting mammal. It exerts a remarkable influence on the secretion of pancreatic juice when injected into other animals. The present article combats the notion that this action is specific for the pancreatic juice, as the writers' experiences demonstrated that it had a similar and possibly even more pronounced action on the secretion of bile.

7. Hyperidrosis in General Paralysis.—The particulars of 54 cases of general paralysis are given, followed from the incipiency of the affection to death. Hyperidrosis was marked in one out of every 9 male patients. It was never observed in syphilitics or hard drinkers and never after the age of 50. It was twice as frequent in winter as in summer, and was never noted in spring or fall. It was always excessive from the start and ceased with equal suddenness, lasting two months on an average, occasionally five. It was always noticed in the second stage of the affection, but there did not seem to be any relation between it and the other symptoms. It recurred later in one instance, but was limited to the brow.

8. Results of Multiple Sections of Cranial Nerves.—On account of a malignant tumor in the neck, the pneumogastric, hypoglossal and sympathetic nerves were cut in the case described. The patient has hemiparalysis and hemiatrophy of the tongue as the result of section of the hypoglossal. Section of the sympathetic has induced slight atrophy of that side of the face, but there is no paralysis. The eyeball is more sunken than normal, probably from paralysis of the tract of fibers in the capsule of Tenon, innervated from the sympathetic. Protrusion of the eyeball is probably due to some permanent irritation of these fibers, while section of the sympathetic induces the opposite effect. The palpebral fissure is wider than normal, and myosis is also marked owing to the lack of the antagonist action of the fibers innervated by the sympathetic. Section of the pneumogastric has caused paralysis of the vocal cord on that side, but no other symptom. The extirpation of the neoplasm required ligation of the carotid which did not cause any disturbance at the time, but complete hemiplegia gradually developed after twenty-four hours on the opposite side, with aphasia, and then gradually subsided to merely traces. Five months later an epileptiform seizure occurred, leaving transient hemiplegia. There were no antecedents of hysteria or epilepsy, and the seizure was evidently a tardy consequence of the ligature applied to the carotid.

10. Myorrhaphy of Levatores Ani for Prolapse of Rectum.—This procedure has been applied as a means of correcting prolapse of the uterus but the two cases reported are the first published in which prolapse of the rectum was treated in this way. A Russian surgeon suggested the method at the Moscow Congress but had practiced only on the cadaver. The first patient was a woman of 40, and the second a man of 65. The prolapse has not recurred in either. The muscles were exposed to the peritoneum, isolated and sutured together by the

inner surfaces or edges. In the female the intervention accomplishes both a myorrhaphy and vaginopexy at the same time.

19. **Functional Tests of the Kidneys.**—Tuffier remarks that the freezing-point, methylene blue, phloridzin and other functional tests of the kidney afford insight into the conditions of only a portion of the total urine for twenty-four hours, while it has always been considered extremely important to base all calculations on the total output. He has been studying the conditions in one of his patients who voided all the urine from one kidney through a lumbar fistula while that from the sound kidney was voided naturally through the bladder. He gives the details which establish beyond question that in this case at least, the proportions between the functional conditions of the two kidneys as determined by all the functional tests known, remained approximately the same at all times. Each kidney performed its share of the urinary task in the same proportion for each half hour as during the entire twenty-four hours. One kidney was affected with hydronephrosis, with slight sclerosis, while the other was sound, and the diseased organ did only half the work of the other. Study of this case confirms the value of the information to be derived from segregation of the urine from each kidney, even for brief, half-hour periods.

20. **A New Bulbar Syndrome.**—Bonnier shows how injury of the large bulbar nucleus, which he calls the nucleus of Deiters, may entail a syndrome distinguished by vertigo, with partial or complete loss of ability to stand, reflex oculomotor disturbances, a condition of nausea and distress, transient auditory phenomena and pains in certain regions of the trigeminal domain. The nucleus is large and may not be affected throughout its entire extent, consequently the complete syndrome is rarer than the partial. He compares these bulbo-protuberantial centers to the small keyboard of an organ. A slight touch to one of its keys sends vast waves of sound sweeping through its periphery, reverberating farther and farther. The symptomatology harmonizes into a coherent and progressive harmony which we can trace back to the bulbar notes played. The syndrome under discussion associates cerebellar phenomena with the reactions peculiar to the third, fourth, fifth, sixth, eighth, ninth and tenth cranial nerves, but the nucleus involved is predominantly a center for the labyrinth. In 97 out of 100 cases of tabes examined by Collet this nucleus was found affected.

21. **Mobilization of Urethra to Remedy Loss of Substance.**—Savariaud has followed the method of mobilization of the two stumps of the urethra suggested by Carl Beck and von Hacker, to unite them after extensive injury or resection of the canal. He describes a case in which he performed this operation with satisfactory results on a boy of 8. The conditions are more favorable for success in a traumatic case than in hypospadias for which the method was originally suggested, owing to the tendency to curvature and to the rudimentary condition of the urethra in the latter.

Revue de Chirurgie, Paris.

22 (XXIII, 2.) Note sur 2 cas de kystes mucoïdes du cou (of the neck) à epithélium cillé dérivés des restes du tractus thyréo-glosse. P. Fredet and M. Chevassu.
23 *Pharyngotomie pour ablation des tumeurs de la portion buccale du pharynx. L. V. Orlow.
24 *Un cas d'anastomose artério-veineuse longitudinale pour artérite oblitérante. Gallois and Pinatelle (Jaboulay's clinic).

23. **Pharyngotomy.**—Orlow points out that tumors developing in the upper, middle or lower portion of the pharynx require entirely different surgical intervention. About a dozen separate methods of treating those in the middle or buccal portion have been devised, but Orlow prefers his modification of Krönlein's method. The semicircular incision instead of starting at the juncture of the lips, commences at the middle of the lower lip, thus averting all danger of injury of the facial nerve. Among the advantages offered by this method is the wide opening up of the field of operation, allowing free access to the tumor and complete oversight of the upper end of the larynx, while it enables the ganglia in the region and extending down into the neck to be readily extirpated. Section of the lower jaw is indispensable in all these operations. A still further advantage is the lesser disfigurement that results from the semicircular incision in the shadow of the jaw, visible only as a symmetrical line on the chin. For benign growths free from glandular involvement, the Trendelenburg method is preferable, but for malignant tumors the method above described is superior to all others, he believes. In 8 of the 10 cases described the patients were in the horizontal decubitus. In case of extensive malignant growths preliminary ligation of the external carotid is required, and in particularly serious cases, also of the internal carotid. One of his patients succumbed to hemorrhage from the external carotid the eleventh day, from an erosion induced by infection of the wound. The other patients bore the operation well, and there were no evidences of broncho-pneumonia afterward. The age of the patients ranged from 36 to 62 years. The tumor was an endothelioma in 2 cases, in one of them shaped like an hour-glass; carcinoma in 3 and sarcoma in 4. It is impossible to maintain asepsis in this region, and the union of the jaw was not always regular. There have been recurrences in 3 and a suspicion of them in 2, but not in the cases of endothelioma. In 1 case the ultimate outcome is unknown. All the patients were in an advanced stage of the affection; the results will be better when intervention can be undertaken during an earlier phase.

24. **Arterio-Venous Anastomosis.**—This article describes the post-mortem findings in the case of arteritis obliterans mentioned in The Journal of February 7, p. 408. The first manifestations are sharp pains in the legs, exceptionally also in the arms, occurring in an adult free from syphilis or other infectious disease. The pain is mostly continuous with exacerbations. Then gangrene develops, limited at first to the toes it gradually encroaches on the leg with a slow and progressive course, usually without effusion. The arterial pulse vanishes far in advance of the gangrene. It is frequently almost impossible to find the arteries as there is no pulse, and they can not be palpated as hard cords as in arteriosclerosis. The arteries elsewhere are small and the pulse is weaker than normal. The leg was amputated at the thigh in the case described. The obliterating lesion consists in a thickening of the inner coat of the arteries, with connective tissue transformation reducing and finally occluding the lumen of the vessel. The process is usually confined to the medium-sized arteries, and is sometimes accompanied by endophlebitis, but the nerves have always been found sound. Courchet collected 13 cases with atheroma or endophlebitis in some, but no known dyscrasia, no infection. Twenty-one other cases have been published in the literature. Some of the patients were apparently cured by amputation, but as the cases were not followed the final termination is not known. Jaboulay's is the third operation on record in which an anastomosis was established between an artery and vein. The opening was found still permeable at the autopsy and the union was complete between the tissues of the two vessels. In the first case published the pains of the dry, spontaneous gangrene to the ankle vanished after anastomosis between the artery and vein had been established. But they recurred later and amputation was performed. In the second case the patient was a man of 72 with traumatic gangrene of three toes. The anastomosis was done at the same time as the toes were disarticulated. The gangrene was arrested and the patient recovered. These cases are described in full by the operator, San Martin y Satrustegui of Madrid in a pamphlet published by E. Teodoro, Madrid, 1902, entitled "Discurso leido en la solemne sesione inaugural en la Real Academia de Medicina, 1902." In all these three cases on man longitudinal anastomosis was established between the femoral artery and vein.

Semaine Medicale, Paris.

32 Letter from America. La douleur rénale provoquée dans le diagnostic, etc. F. Munch. (Kelly's method.)
33 Ibid. Le traitement des tumeurs malignes à New York.

25. Peritonitic Origin of Liver Colic, Etc.—Tripier's further experience has confirmed more and more the assumption which he has long been proclaiming in regard to appendicitis, that the pain in affections of the abdominal viscera is due solely to inflammatory processes in the surrounding peritoneum. He formulates the law that none of these affections are accompanied by attacks of pain unless the surrounding peritoneum is involved in some acute or subacute inflammatory process, and that the pain is more intense the smaller the quantity of the fluid exudate. The same law applies to all the serous membranes, the pleuræ, pericardium, etc. Certain pains manifestly due to a flare-up of peritonitis, when it is situated near the liver, may deceptively simulate liver colic. Perigastritis due to a prepyloric ulcer in one case was diagnosed as liver colic without icterus, and the patient took several courses at Vichy until the progressive character of the trouble compelled a laparotomy. In three-fourths of all the cadavers that came to autopsy there were evidences of healed subhepatic peritonitis with adhesions, and the gall-bladder showed signs of old inflammation in the majority of cases, the symptoms of which had generally passed unrecognized during life. Some contained a calculus and others no sign of lithiasis. Instead of the general tendency to incriminate the appendix and to regard other concomitant abdominal lesions as secondary to inflammation at this point, the autopsy findings in Tripier's researches indicate that the gall-bladder is generally responsible, and that the appendicitis is itself secondary. There can be no question that many cases of mild or subacute inflammation of the gall-bladder are overlooked in the clinic and yet they may be the starting-point for a neighborhood peritonitis and infections in the rest of the abdomen, near or remote, especially in the vicinity of the appendix and organs in the small pelvis, more rarely by contiguity in the pleuræ and pericardium. Instead of an "appendicular pleurisy," the facts observed in the cadavers examined speak for the reverse, a descending instead of an ascending infection. The adhesions left from these mild inflammations of the peritoneum around the gall-bladder have evidently been mistaken for physiologic anomalies in many cases. When noticed as pathologic no one seems to have thought of comparing them with the pathologic past of the subject. In looking for them the viscera must be examined *in situ* to note the relations and adhesions between them instead of taking them out singly for examination.

27. Pseudo-Heart Disease.—Barié describes four groups of what he calls "false cardiacs." They are usually adults or youths, all either dyspeptics, smokers, neuropaths or victims of incipient tuberculosis. Notwithstanding their palpitations, their pains in the heart region and other symptoms, the heart will be found sound. In the dyspeptics some irritation from the lining of the stomach is transmitted by the sympathetic and induces a reflex excitation of the capillaries of the lung, causing spasmodic contraction. This raises the pressure in the pulmonary artery system; the right heart becomes dilated and tricuspid insufficiency results. Experience has shown that this reflex action occurs exclusively with trivial digestive disturbances and is never observed in serious conditions. The same syndrome may also result from a small calculus in the biliary passages. This pseudo-heart disease is most frequent in neuro-arthritics. It is sometimes the initial manifestation of incipient tuberculosis. In this case the palpitations may be accompanied by tachycardia, or the latter may occur alone and may precede by six months or a year any appreciable symptoms on the part of the lungs. The heart symptoms may be due to a dyspeptic condition very common in incipient tuberculosis, or to compression by some glandular involvement or to actual tubercular involvement of the heart. There is also a symptomatic bradycardia observed in incipient tuberculosis, but it is very rare. The diagnosis in these tuberculous cases is difficult as the subject attributes his symptoms to heart disease. An aid in differentiation is the arterial pressure which is almost invariably low in uncomplicated incipient tuberculosis, and the phosphaturia, which is also common at this stage. Radioscopy may likewise reveal a lesser transparency of the apex of the lung, as well as the deficient excursion of the diaphragm on the side affected. The potassium iodid test proposed by Striker may also prove useful in the differentiation, and serum diagnosis. Barié also describes the attacks of pseudo-angina pectoris, and the pseudo-heart disease noticed at the time of puberty in girls and at the menopause as also in certain affections of the uterus and adnexa, in gout, diabetes, etc.

Centralblatt f. Gynaekologie, Leipsic.

34 (No. 6.) Die Drainage nach Laparotomie. A. Sippel.—Advocates rinsing with salt solution and draining.
35 Abortion by Silver Cauterization of Cervix. Piering.—Geschichtliche Bemerkung.
36 Ruptura cervicis centralis anterior sub abortu. O. Weiss.
37 Fall von Prolapsus uteri inversi. E. Funke.

65 Tritt Placenta previa auch ohne Blutung auf (without hemorrhage)? Burger.
66 *Die streikenden Geraer Kassen-Aerzte und der Vorstand des Leipziger wirtschaftlichen Verbandes (the Battle of the Clubs at Gera). Hartmann.

46. Surgical Treatment of Stricture of the Esophagus.—Lindner's experience has been no better with carcinomatous stricture than that of others. About 18 cases have been published; the patients died shortly after the operation in 5, but the remainder survived for a longer or shorter time, none for more than two years. He has operated on 3 but none survived more than a few days. He has used Frank's method of making a gastric fistula in 15 cases of benign stenosis of the esophagus

and the results for the first two or three months were ideal, but after this the fistula became incontinent and the patients wasted away. He has now abandoned it altogether. He has been very successful with von Hacker's method of "endless sounding," and has found that very few cases prove rebellious to it. In one recently, a boy of 7, the multiple strictures caused by drinking lye, proved impermeable to the sounds, and as a last resort the esophagus was exposed its entire length in the neck, and from this point the sound was finally successfully passed into the stomach and the strictures dilated. The stomach fistula healed in a week, and a week later the sound could be introduced from the mouth. The wound in the neck was simply coaptated with plaster. The lad was trained to keep up this endless sounding to prevent the stricture from closing up again. He soon learned to introduce the sound himself and was dismissed in good condition.

54. **Always Ready Aseptic Dressing for Wounds.**—The dressings are rolled up separately in an aseptic cover. Two strips of parchment are placed in each in such a way that by pulling on the parchment the dressings can be opened and spread out ready for application, without being touched by the hand. The cut shows how this is accomplished.

66. **The Strike at Gera.**—This article is by the president of the Union for the Protection of the Economic Interests of the Physicians of Germany, which has been sustaining the physicians at Gera in their resignation of their positions as medical officers to the great textile industries sick benefit company. He reviews the history of the battle of the clubs in Germany and extols the action of the Gera physicians as a brilliant example for the entire profession by their united stand for ethical principles and their brave perseverance in the course once decided on. He remarks that it is the first time in Germany that physicians have taken such a decided step as to refuse to attend the policy holders in the company, even as private patients. The responsibility for the conditions rests with the officers of the company and with the local authorities which have a right to compel the company to provide the medical attendance its charter calls for. Indirectly it rests on the policy holders, as they elect the officers and they should select men incapable of injustice. In regard to the lack of sympathy on the part of the general public, he remarks: "Since when have physicians ever received any sympathy from the public in their claims? Have the decisions of our medical chambers ever met with public sympathy? The stand of the profession in regard to the charlatan question raised a great hue and cry in the lay press in regard to our short-sighted and narrow-minded policy. Have we ever won any friends by our stand in regard to medical women, the technical schools, etc.? Any one who claims his rights may count on the hostility of the multitude, and we physicians will have to accustom ourselves to accomplish our just purposes in spite of the ill-will not only of the general public but also of the public authorities."

73. **Choreic Psychopathy.**—Mircoli describes a few typical cases to illustrate his idea that the various forms of chorea, if accompanied by mental disturbances or change of character, have each a special type of psychopathy. The degenerative form of chorea is accompanied by psychic disturbances such as are noted in degeneracy from any cause, hereditary or acquired. The rheumatic form is accompanied by caprices and a tendency to agitation. In the psycho-traumatic variety the mental phenomena observed are those of depression with a tendency to melancholia. It may be possible sometimes to trace back to the cause of the chorea by observing the character of the psychopathy accompanying it.

78. **Calomel in Pneumonia.**—Bertazzoli has long been proclaiming that calomel in infectious diseases is able to lower the temperature to a degree that amounts to a pseudo-crisis. It causes revulsion in the intestines, he asserts, diverting part of the blood from the inflamed organs and in pneumonia thus averting the danger of edema of the lungs, while regulating the circulation there. The calomel passages carry away from the organism a quantity of the toxins which otherwise would circulate in the blood and depress the nervous system, adding their dangerous effect to the intoxication with carbonic acid gas, so intense in this disease. The microbicidal action of calomel supplements its effect in other ways.

80. **Serum Treatment of Leukemia.**—Rabbits and sheep were inoculated with leucocytes derived from patients with leukemia. The blood withdrawn was set aside to settle spontaneously which allowed the leucocytes to be collected free from red corpuscles or serum. The rabbits thus received forty-seven endoperitoneal injections of 5 to 10 gm. of leucocytes in the course of thirty to forty-five days. The sheep received nine injections in the external jugular vein at intervals of two to twelve days. The serum of the animals thus treated displayed *in vitro* marked destructive action on human leucocytes, and 3 patients with leukemia were treated with it by subcutaneous injections of about 1 to 5 c.c. of this serum, usually on alternate days. One patient with 560,190 leucocytes before treatment, received twenty-six injections and the leucocytes then numbered 375,720 per mm. The enlarged spleen was also much reduced in size during the serum treatment. The second patient was in a very advanced stage of the disease and no benefit was apparent from the twenty-eight injections made. In the third case the leucocytes fell only by 7,660 from the original figure of 500,960 after eleven injections, a total of 42 c.c. of serum in thirteen days. The proportion of uric acid in the urine rose from .70 to .95 and the size of the spleen was very much reduced. The injections caused no by-effects in any instance and were perfectly tolerated.

82. **Jez's Extract in Treatment of Typhoid.**—The extract is made from the organs of animals injected two or three days before with typhoid bacilli. Sibaldi was much impressed with the rapid improvement that followed its use in two exceptionally severe cases of typhoid fever. As much as 200 c.c. can be injected without disturbances. The heart and pulse are favorably affected, as also the nervous symptoms. It induces copious urination and the temperature subsides. The extract is given by the spoonful every two hours. Its effect is manifest by the second day and by the third day two liters of urine were voided. In a third case the extract was given in hopes to abort or cure a prostatic abscess in the course of typhoid fever, but no appreciable benefit was derived. The patient succumbed.

85. **Cutaneous Manifestations of Malaria.**—Vaccari has observed a few cases of a dermatosis resembling urticaria, but free from pruritus, which accompanied attacks of malaria and vanished under exhibition of quinin. Other Italians have

reported an exanthem resembling that of scarlet fever or measles, with desquamation, occurring likewise associated with or as a manifestation of malarial infection. Vaccari observes that these cutaneous phenomena in malaria indicate a severe type of the disease, and thus have a certain value for the prognosis.

87. **Ferric Arseniate in Anemia.**—The soluble ferric arseniate used in Italy has been applied by Fedeli in twenty cases of anemia with exceptionally favorable results, as he shows by the clinical histories. The age of the patients ranged from 10 to 38. Zambeletti's citro-ammoniacal preparation was administered by subcutaneous injection for two or three months and all the patients gained several pounds in weight, while the composition of the blood and the general health returned to normal.

95. **Toxoids in Tetanus Cultures.**—Bonome announces that he found it possible to attenuate the tetanus toxin in cultures by addition of coli toxins.

96. **Arrhythmia in Relation to Chronic Degeneration of Myocardium.**—Francesco's experience indicates that arrhythmia is invariably pronounced when the musculature of the auricle is in a condition of fibrous degeneration, with or without the involvement of the musculature of the ventricle in the process. On the other hand, degeneration of the auricular appendage, even with advanced degeneration of the walls of the ventricle, is not accompanied by any arrhythmia.

99. **Saccharomycetolysis.**—Sanfelice states that the serum of animals treated with the proteins of blastomycetes contained antibodies which transformed the parasites into fuchsinophile bodies.

102. **Etiology of Acute Ascending Paralysis.**—A man of 55, with no special antecedents except a family tendency to excessive hemorrhages from slight cuts, noticed slight fever and delirium, with pains and weakness in the legs and round red spots on the thighs, extending later over the body. Urination was difficult. By the eighth day the right arm became completely paralyzed, and later the left, and lesions developed in the buccal cavity. Except for the first few days the patient's mind was clear during the entire affection, which progressed to a fatal termination, with symptoms of edema of the lungs, ten days after entering the hospital and twenty-seven after the first manifestations of the trouble. Examination of the blood the twenty-second day revealed large numbers of the staphylococcus albus. Thoinot and Masselin have reported experimental research on rabbits, in which they induced paralysis by inoculation with the staphylococcus aureus. Strümpell was able to cultivate the staphylococcus from a case of acute transverse myelitis and pachymeningitis. Eisenlohr also found this micro-organism in the central nervous system in a case of Landry's paralysis, as also Wokenius in a case of multiple neuritis (St. albus). Sukhanoff has also published a case of multiple neuritis and abscesses in the skin and internal organs due to staphylococci, accompanied by melancholia and Korsakoff's psychosis. Dogliotti also derived staphylococci from the pus of an abscess in the medulla oblongata. In the case described in the present article the probabilities are in favor of the assumption that the acute ascending paralysis was the consequence of general infection with the staphylococcus albus, and that both the spinal cord and the peripheral nerves were affected, the former predominantly. Both cutaneous and tendon reflexes were abolished, and the paralysis was most marked in the upper extremities. The blood was examined again immediately after death, but this time the results were negative. The germs may, therefore, vanish from the blood during the course of staphylococcemia, which explains the rarity of its discovery.

104. **Differentiation of Malignant Tumors in Pleura.**—Golubinin relates in detail a case to illustrate the various points important for the diagnosis, the pain, the pleuritis, usually with effusion, but distinguished by the absence of fever. The effusion is seldom serous or purulent, more frequently it is hemorrhagic, sometimes chylous. It is not as abundant nor as diffuse as in case of ordinary pleuritis. The sputa become blood stained if the growth involves the lungs. The side of the thorax is also liable to become contracted from development of cicatricial tissue within. The most important signs are the rapidly developing anemia and cachexia, the presence of particles of the tumor in the pleural effusion and the discovery of enlarged glands and metastatic nodules in the skin and subcutaneous tissue, the protracted, non-febrile course, the irregular outline of the dullness and occasionally the severe pains.

105. **Review of Literature on Lungs and Pleura in 1901.**—Nearly a hundred pages are devoted to this review of 685 communications published in all quarters of the globe. American literature is extensively represented.

106. **Treatment of Sydenham's Chorea with Arsenic.**—Timasheff describes his experience with 26 cases of chorea. He found that an aqueous 1 per 1000 solution of arsenious acid afforded the best results. He deprecates the large doses recommended by Comby, and seldom gave more than three teaspoonfuls a day, finding that the desired results were attained fully as rapidly as with the larger doses. He thinks that more attention should be paid to the underlying cause of the affection. He was unable to detect any special relations between the duration of the disease and the length of treatment or the prevention of relapses.

107. **Bullet Wounds of Skull.**—Tikhoff describes two cases to support his plea of the necessity of trephining as a routine measure in bullet wounds of the skull, and the harm that may result from neglect of this measure.

108. **Restoration of Nasal Septum.**—Kuzmin makes two parallel incisions in the upper lip close to the median line, but not reaching to the extreme outer margin. A transverse incision close to the nose allows a rectangular flap to be raised, still connected at its base in the margin of the lip. The flap is then sutured to the nose in such a way as to give the aspect of the normal septum. After eight to ten days the flap is severed completely from the lip and the suturing to the

nose completed. The edges of the wound in the lip are brought together and sutured. The cosmetic effect is very satisfactory.

109. **Lichen Planus of Mucous Membranes.**—In Tchlenoff's case the patient exhibited typical lichen planus on face and neck, and the same lesions were also prominent in the mouth. He reviews the similar cases on record and observes that lichen planus has been noticed on the mucosa of mouth, throat, anus and urethra. It may develop at these points primarily and without appearing on the skin, but is usually secondary to cutaneous manifestations. The prognosis is generally favorable, especially under prolonged and energetic administration of arsenic.

110. **Tuberculous Stricture of Intestine.**—Nikolsky has been studying the records of 150 cases of tuberculous stenosis of the intestines, as published in the literature. They can be grouped as those with an acute sudden onset, those with a gradual development and those with a latent course. It is secondary in about 50 per cent. of all cases, and usually manifests itself between 20 and 40 years of age. Before 10 and after 60 it is extremely rare, although three cases are known before 9 and one case after 60. The stricture generally develops in the lower part of the ileum. Multiple strictures occur nearly as frequently as the single, and multiple strictures prove almost invariably to be of a tuberculous nature, as also all strictures whose etiology is not clear. Treatment is exclusively surgical, the sooner the better. The mortality after resection was 30 per cent., and after enteroanastomosis 17 per. cent.

116. **Treatment of Tetanus With Brain Emulsion.**—Tikanadze reviews the four cases of tetanus treated with brain substance on the principle of "side chain immunity," which have been published by Krokiewicz, Schramon, Schuster and Rostovtzeff. All the patients recovered, and he describes a case personally observed in which the recovery was also rapid and complete. After the failure of chloral and other measures in a severe case of tetanus in a girl of 11, he commenced on the eighth day to treat her with brain emulsion. He obtained the head of a freshly slaughtered young pig and removed the brain and ground it in a sterilized porcelain mortar with sterilized physiologic salt solution, until a reddish fluid was obtained, which passed readily through the medium sized tip of the syringe. He thus injected subcutaneously 10 gm. of brain substance emulsified in 30 c.c. of the salt solution. Improvement was apparent by the next day. He repeated the injection again the next and the following days, and recovery was satisfactory. He adds his appeal to Rostovtzeff's that physicians should not fail to use the brain emulsion in cases of tetanus, especially when tetanus antitoxin is not obtainable.

118. **Cutaneous Hyperalgesia in Affections of Internal Organs.**—Gebstein urges further research in this line, as it may clear up the diagnosis in many dubious cases if the laws governing it can be determined. He describes and illustrates a dozen typical cases to show the variety in the location of the hyperalgesia. The region affected was sometimes, but by no means invariably, a girdle or zone, and it did not always correspond with Head's outlines. He found that hyperalgesia occurred regularly in certain regions, with an affection of any of the internal organs, but it was not an invariable accompaniment of an internal affection. The hyperalgesia observed in his cases always vanished on recovery from the internal affection.

119. **Professional Pollutions and Spermatorrhea.**—Bogoraz has examined hundreds of railway employes, and has found that pollutions and spermatorrhea are very common among them. Engineers are especial sufferers. The nervous strain of their profession and the constant jar of the engine causing friction between the sexual organs and the clothing, with the venous congestion in the lower part of the trunk and legs, cause constipation and frequent pollutions and spermatorrhea. He gives tables showing the comparative proportion affected among the various groups of railroad employes. He adds that they attribute the exaggeration of this pathogenic tendency to the introduction of the "American" system of long trips and sleeping on the cars.

126. **Treatment of Acute Pyemia.**—Wernitz gives the temperature curve and details of two severe cases of septic puerperal infection rapidly cured after application of the almost continuous rectal irrigation, which he described also in another article, of which an abstract was given in The Journal of March 14, p. 745.

128. **Treatment of Smallpox with Repeated Vaccinations.**—V. O. Hubert published in Russia, in 1886, an account of remarkably favorable results obtained by him in more than 200 cases of smallpox which he had treated by repeated vaccination, vaccinating the patients two or three times a day during the first six days of the disease. All recovered. Other Russian writers have published similarly favorable reports on a smaller scale, and Braslavsky now adds eight more cases to the list. The results were eminently good, although half of his cases were severe. He considers himself justified in recommending the method for wider adoption in the treatment of "natural" smallpox.

131. **Revival of Isolated Heart After Death.**—Kuliabko has continued his researches previously reported on the possibility of reviving and inducing spontaneous pulsation in the heart of warm-blooded animals two to four, and even five days after death of the animal. He announces that he has succeeded in accomplishing the same in the case of the heart of a three-months infant on the second day after the death of the child from pneumonia. A canula is inserted in the aorta, as suggested by Langendorff, and warm Locke's solution, saturated with oxygen, is forced through the heart. This is a solution of equal parts of $CaCl_2$, KCl and $NaHCO_3$, each .02 per cent.; NaCl, .9 per cent., and dextrose .1 per cent. After this fluid had coursed through the heart for about twenty minutes, almost imperceptible movements were noticed in the right auricle, spreading thence to the right ventricle, whereupon the entire heart commenced to beat. This spontaneous pulsation of the

heart continued for more than an hour. The more or less faintly rhythmical pulsation of the ventricles and auricles under the influence of artificial irrigation with the above fluid was a wierd sight, knowing that the owner of the heart had been dead thirty hours. It remains to be seen whether the facts thus learned will prove of any practical value, but they certainly suggest, he remarks, the possibility that, in exceptional cases, artificial irrigation of the heart with a warm salt solution might possibly be attempted as the very last resort.

133. **Primary Tuberculosis of Spleen.**—Romanoff's patient was a man of 80. It is the tenth case that has been published, he states. The lesion was of the "spleno-hepatic" type, described by Collet and Gallavardin. When admitted to the hospital (Tomsk), a few days before his death, the spleen formed a large tumor. He stated that he had been healthy except for a period of five months forty years previously, when he had expectorated blood and had more or less fever. The microscopic findings are described in full.

134. **Resuscitation in Asphyxia Neonatorum.**—Minkevitch seats the child on a flat surface and bends the trunk backward over a solid roll of cloth, which elevates the thorax while allowing the head to touch the flat surface of the table beyond. The trunk is then brought up and carried forward until the head is between the infant's knees. A few repetitions of the procedure are usually sufficient.

143 Case of Ruptured Urinary Bladder: Operation and Recovery. Hugh Lawrie.
144 *The Open-Air Treatment of Syphilis. E. H. Douty.

136. **Simulation of Appendicitis.**—Barker reports his experience with conditions simulating appendicitis among which are ruptured pyosalpinx, strangulated ovarian cyst with twisted pedicle, strangulated omentum, perforated gastric ulcer, retrocecal hernia, broken down caseating glands, ileocecal cancer with abscess, hematoma of broad ligament, reduction of hernia *en masse* and intussusception. Some of these are rare, while others such as ruptured pyosalpinx, broken down caseating glands, etc., are much more common. Intussusception ought never to be mistaken for appendicitis, yet it is. In some other conditions like gastric ulcer, the diagnosis may be very difficult.

137. **Adenocarcinoma of the Rectum.**—In this second lecture, Ball describes adenocarcinoma, which, while not exclusively the type of malignant disease occurring in this region, is still by far the predominant one. Hardly 5 per cent. of malignant growths there situated are of any other variety. It is met more frequently after middle age, but many cases are recorded in which it commenced in early life and he has seen it at the ages of 16 and 18 respectively. Both sexes appear to be affected alike. When met in young persons it is apt to be highly malignant and rapid in its course. He describes two forms, one commencing as a flat tubercle, ending in a sort of oval ulcer, spreading over the circumference of the bowel. The other, a slower type occurring in older persons without the exuberant edges, is a growth less in quantity and more atrophic, with a tendency to dense connective tissue formation around the ulcerated surface. The morbid histology is described at length and illustrated. The symptoms are, first, diarrhea, a good deal of mucus, etc., and later symptoms of obstruction and pain. Involvement of the other organs may occur if it progresses. He insists on the importance of an early diagnosis and of digital examination to detect the condition. This can be performed, if necessary, under anesthesia by the bimanual method. If the tumor is freely movable and no enlarged glands or metastatic growths can be felt, and the general condition of the patient is good, it is suitable for operation. If there is limited adhesion or lymphatic involvement, operation may be undertaken, but the prognosis is not so good, but if there is an extensive involvement of the adjoining organs and metastatic growths can be detected in the abdomen, operation is absolutely contraindicated.

141. **The Diphtheria Bacillus in Atrophic Rhinitis.**—Syms has investigated twenty-three cases of atrophic rhinitis for the diphtheria bacillus and found an organism closely resembling it in twenty of the cases. Control examinations were made on healthy noses, and in no instance was a similar microbe found. Culture experiments in one or two cases also proved the pathogenicity of the organism. There were certain slight differences observed, the bacillus was more curved and thinner and more highly metachromatic than the Klebs-Loeffler bacillus and rather closely resembled the tubercle bacillus. He offers the following conclusions:

If the foregoing facts can be sustained, and the identity of this bacillus with the Klebs-Loeffler bacillus can be established, then we may regard atrophic rhinitis as a chronic form of nasal diphtheria. In addition to the bacteriologic evidence the following points may be considered in support of this theory:

1. In diphtheria the accessory sinuses of the nose are constantly infected. Bacilli may remain in the sinuses for prolonged periods, exciting a purulent, sero-purulent, or serous discharge.

2. Chronic suppuration in the accessory sinuses is, in the opinion of many eminent rhinologists, the direct exciting cause of the conditions of ozena and atrophic rhinitis.

3. Multiple cases of atrophic rhinitis in the same household occur from time to time, as one would expect if the process were a true infection. Thus Terez records twelve instances in which there were two or more sufferers in the same family. This is a point I have not inquired into amongst my own series of cases.

4. An attack of diphtheria may be the starting point of atrophic rhinitis. Only two patients in the present series dated the onset of symptoms from an attack of diphtheria, but the history of all was not inquired into.

5. Atrophic rhinitis, like diphtheria, attacks females more than males; it is a disease of early life, and induces a pronounced anemia and leucocytosis.

6. Atrophic rhinitis has been successfully treated by diphtheria antitoxin. With regard to this point, my experience has been so limited that I do not feel justified in saying more than that if repeated moderate doses of antitoxin are administered regularly, amounting in all to 20,000 units, marked relief of symptoms results.

7. In atrophic rhinitis the type of diphtheria bacillus does not alter during the progress of the case, a fact which Woodhead has recently found to hold true in acute faucial or nasal diphtheria.

He says, apart from the theory that atrophic rhinitis is the chronic form of nasal diphtheria, a practical point is that cultures taken from these noses may cause isolation of patients

142. **The Bilberry.**—Sawyer notices the bilberry communication in a previously issued abstract in THE JOURNAL of February 28, ¶19, p, 610, and suggests further investigation of the subject.

144.—This article has appeared elsewhere. See THE JOURNAL of February 14, ¶18, p. 469.

145 Some Famous Medical Officers of the Army. Norman Moore.
146 *Gastroenterostomy and Its Uses, with a Description of the Operation as Performed by the Author. A. W. Mayo Robson.
147 Lunacy and the Lay. T. Outterson Wood.
148 *The Gelatin Treatment of Hemoptysis. H. M. Tickell.
149 *The Uses of X-Rays in Ophthalmic Surgery. M. S. Mayou.
150 *The Treatment of Epileptics. Fletcher Beach.
151 The Theory of Retinoscopy. E. Kenneth Campbell.
152 A New Method of Treating Fractures of the Shaft of the Femur. J. P. Lockhart Mummery.

146. **Gastroenterostomy.**—Robson reviews the methods and indications of this operation. He prefers the posterior operation, which is favored by his experience. The later results of operation have been much more favorable than the former. While only three or four years ago, from what he was enabled to collect from all sources, there was a mortality of 36.4 per cent., now he can point to a considerable series of cases with a mortality of only 5 per cent. He is not in favor of the Murphy button for this operation, though it is used almost exclusively by some German surgeons. He would employ it only when the greatest speed was imperative. Complications such as regurgitant vomiting, subsequent contraction of the new orifice, pneumonia or pleurisy, peptic ulcer, adhesions, causing intestinal obstruction, lack of union, passing of the small intestine through the loop, etc., are all noted. He gives a long series of conditions which indicate this operation:

Pyloric stenosis, from either simple or malignant disease, congenital forms, congenital pyloric atresia, chronic gastric ulcer, with doubtful tumor too extensive for removal, not necessarily associated with stenosis, duodenal cancer or tumor causing obstruction, and hour-glass stomach are indications for gastroenterostomy. In perigastritis, adhesions around the pyloric, causing obstructive symptoms, may be too extensive for gastroenterostomy. Dilatation of the stomach, depending on pressure outside the pylorus from inoperable tumor of the pancreas, liver, or gall bladder are imperative indications, as soon as the diagnosis is established. In the second series, cases in which it is indicated after failure of medical treatment, are included acute or chronic gastric ulcer, duodenal ulcer, hemorrhage from such ulcer, persistent spasm of the pylorus, or Reichmann's disease with gastric dilatation, hyperchlorhydria, persistent gastralgia, tetany of gastric origin, acute gastric dilatation not yielding to lavage and general treatment, pancreatitis secondary to gastric ulcer, certain cases of jaundice depending on gastric or duodenal ulcer, leading to thickening around the common bile duct and simple atonic dilatation of the stomach after failure of lavage and general treatment. In some of these cases operation is advisable simply to obtain physiologic rest and favor natural processes. The operation is here only a last resort when everything else has failed.

148. **The Gelatin Treatment of Hemoptysis.**—Tickell recommends the use of gelatin by the rectum in cases of hemoptysis, and reports a case. Since then he has applied the same method to other patients with the same favorable results. The solution is prepared as follows: 50 grams of gelatin are dissolved in one and one-quarter liters of boiling water and boiled very gently for an hour, when the volume is reduced by evaporation to one liter. This solution is then cooled down to body temperature, and one-quarter liter is slowly passed into the rectum from an ordinary irrigator at a height of two or three feet. The injection does not cause any action of the bowels, is entirely painless, and there is no danger of infection if properly managed, no rise of temperature and, of course, no necrosis. The treatment can be carried out in general practice. He would give it three times a day, until the sputum ceases to show any trace of blood.

149. **The X-Rays in Ocular Surgery.**—Mayou points out the uses of the *x*-rays in the location of metallic foreign bodies in the globe and gives a method of employing them. He also recommends them for rodent ulcer of the eyelid and trachoma. In the latter condition he does not use a mask, but just seats the patient about nine inches from the anode, with a moderately soft tube and a current of six amperes for a two minutes' exposure on four to six successive days, according to the case. If there is much injection, or the case is very acute, four will be sufficient. Later he employs it two or three times a week and has had excellent results.

150. **Epilepsy.**—Beach believes in the bromids for the drug treatment of epilepsy, and prefers the compound of bromid of sodium, ammonium and potassium. If only one is required he gives the bromid of ammonium, and, in some cases, has found the combination of antipyrin with bromid useful, giving it in doses of 10 gr. three times daily for adults and in a lesser quantity for children. Where the fits occur at night, he gives a double dose at bedtime and, if they are frequent, a single large dose only at that time. If they come in the early morning, he gives the dose before the patient rises and has him remain in bed an hour after taking it. He has not great faith in chlorid reduction in these cases, but would give tonics, such as cod liver oil, and keep the bowels well open and occasionally a high saline rectal douche should be given.

153 Notes on Case of Omunono (Yaws). A. Yale Massey.
154 *Beri-Beri in Queensland. Edward B. Ormerod.
155 Malaria and Malignant Diseases in Hot Climates. James Cantlie.

154. **Beri-Beri in Queensland.**—Ormerod describes the conditions of life of the Queensland bushman, whose diet consists mainly of flour, salt meats, sometimes condiments and tea with every meal and between them. The water is very bad, and is often infected by dead animals, etc. Artesian wells are being introduced, which contain more or less magnesia, sometimes causing slight urethritis and general purging at first. Another source of infection is in the dust storms which occur. Rainwater is also used considerably. He has not met any cases of peripheral neuritis or beri-beri in those who only drank rainwater from tanks.

156 *An Analysis of One Thousand Consecutive Cataract Extractions. (To be continued.) F. P. Maynard.
157 *Neurasthenia in Anglo-Indians. E. F. Gordon Tucker.
158 Notes on the Origin of the Presidency General Hospital, Calcutta. (Continued.) D. M. Moir.
159 *Note on the Bacteriology of Dysentery and the Value of the Serum Test in Its Differentiation. Leonard Rogers.
160 Glioma of the Retina. B. H. Nanavatty.

156. **Cataract Extractions.**—One thousand cases are here analyzed, including the 300 published in 1901. Maynard describes his methods of examination and his results, which were good in 89 per cent., indifferent in 5.7 per cent., and bad in 4.5 per cent. and unknown in eight cases. What he calls good is vision ranging from 6.36 to 6.6 with correcting glasses; indifferent results where the sight was bad, but sufficient to enable the patient to move about alone, and bad results where the sight was lost. He finds a family history in nearly 24 per cent. of his cases. The more intelligent the patient the more likely is the family history to be forthcoming. Of the other associated diseases, diabetes occurred in six cases, and the patients all did well. Fourteen patients had bronchitis and various other disorders occurred, but it does not appear that they affected the success of the operation very much.

157. **Neurasthenia in Anglo-Indians.**—Tucker recognizes two forms of neurasthenia, in men that from hepatic insufficiency, and in women a uterine derangement type, both of which are described at length, and the post-febrile group, which may occur in either sex. He thinks early and judicious treatment will prove successful in most cases. Many patients are allowed to go to the bad from neglect. The constant taking of alcoholic stimulants in small quantities to keep up brain energy is a very bad practice in male cases, as it accentuates the dangerous condition of the digestive organs. The patient's life should be carefully regulated, alcohol abstained from entirely or restricted to meals, amount of tobacco reduced, diet regulated, the use of Carlsbad salts in the early morning for a laxative, the teeth should be looked after, mild exercise taken once or twice a day to excite the action of the skin, but drafts should be carefully avoided after it and a flannel cholera belt should be worn at night, especially in the hot weather. Cold baths are injurious and should be prohibited. If the digestion is sluggish, a bitter, acid or some drug that will promote the functions of the intestinal canal is important, but the most important thing is mental rest. The patient should be told that he is suffering from no organic disease and should give up responsibilities. In women many cases are due to subinvolution, which is very largely overlooked, and the patients treated for anemia, dyspepsia, etc. The responsibilities of housekeeping and the care of the children should be removed. The patients should be advised to lay up for four weeks, passing the day on a couch and local treatment given for the uterus, hot vaginal douches in the horizontal position, massage of the limbs, etc.

159. **Dysentery.**—Rogers finds that in the cases which he has studied the organism resembles the Shiga bacillus. His observations point to the conclusion that the common form of India dysentery, prevalent in jails and other institutions, and not followed by the large tropical liver abscess, are produced by the Shiga bacillus or one very like it and can be differentiated from the much rarer and usually complicated cases of amebic dysentery by the positive serum reactions with the Shiga bacillus. His findings agree very closely with those of Flexner in this country.

New Patents.

Patents of interest to physicians, February 17 and 24:

720783. Antiseptic attachment for telephone mouthpieces. Charles W. Clough, Watsonville, Cal.
721032. Electromedical belt. Frank Farmer, Richmond, Ind.
720918. Disinfectant distributing device. Samuel Hesketh, Auckland, New Zealand.
720812. Vaccination shield. Robert W. Johnson, New Brunswick, N. J.
720599. X-Ray tracer. Friedrich Moritz, Munich, Germany.
720863. Atomizer. Jacob Waldman, New York.
720865. Pneumatic massage apparatus. Robert Watson, Washington, D. C.
720648. Syringe. Edward B. Wilder, St. Louis.
12084. Re-issue, Composition for disinfecting or other purposes. Henry S. Blackmore, Mount Vernon, N. Y.
721162. Hemostatic bandage. Eduard E. Denain, Paris, France.
721185. Apparatus for administering anesthetics. Wm. A. Heckard, Indianapolis.
721574. Ankle-supporting corset-shoe. John J. Lattermann, New York.
721575. Maternity corset. Mary E. Leighton, New York.
721587. Operating table. Charles Lyons, Columbus, Ohio.
721454. Prescription file. John H. Lytle, Delphi, Ind.
721603. Truss. Henry T. Prange, Kalamazoo, Mich.
721489. Making citrate soluble phosphates. Wilhelm Wolters, Magdeburg-Buckau, Germany.

The Public Service.

Army Changes.

Movements of officers of the Medical Department U. S. Army, under orders from the Adjutant General's office, Washington, D. C., from Feb. 21 to 28, 1903:

Ames, Roger P., contract surgeon, U. S. A., now at New Orleans, will proceed to Fort St. Philip, La., and report in person to the commanding officer of that post for duty and by letter to the commanding general, Department of the East, to relieve Contract Surgeon Oliver H. Buford, U. S. A., who, on being thus relieved, will proceed to his home, Cartersville, Ga., and, on arrival, report by letter to the Surgeon-General of the Army for annulment of contract.

Mason, Charles F., major and surgeon, having complied with the requirements of Paragraph 1, Special Orders No. 26, Feb. 12, 1903, Department of Texas, will proceed not later than Feb. 28, 1903, to rejoin his proper station.

McAndrew, Patrick H., first lieutenant and asst.-surgeon, having reported his arrival at San Francisco, in compliance with orders heretofore issued, will proceed to Jefferson Barracks, Mo., and report in person to the commanding officer of that post for duty, and by letter to the commanding general, Department of the Missouri.

Tweedie, H. V., contract surgeon, U. S. A., is granted leave of absence for one month.

Navy Changes.

Changes in the Medical Corps of the Navy, for the week ending March 7:

Surgeon C. Biddle, detached from the Naval Hospital, Philadelphia, and ordered to the Navy Yard, League Island.

Surgeon E. S. Bogert, detached from the Recruiting Rendezvous, Buffalo, and ordered to the Philadelphia Naval Hospital.

Surgeon J. C. Byrnes, detached from Navy Yard, New York, ordered home and granted three months' sick leave.

Surgeon O. Diehl, detached from Navy Yard, League Island, and ordered to the *Oregon*, sailing from San Francisco, March 19.

P. A. Surgeon F. C. Cook, detached from Naval Hospital, Newport, R. I., and ordered to the *Nevada*.

P. A. Surgeon R. C. Holcomb, detached from the Naval Hospital, New York, and ordered to the Naval Hospital, Newport, R. I.

Asst.-Surgeon F. W. S. Dean, ordered to the Naval Hospital, New York.

Asst.-Surgeon R. L. Sutton, ordered to the Naval Hospital, Washington, D. C.

A. A. Surgeon J. B. Mears, ordered to the Naval Recruiting Station, Buffalo, N. Y.

Asst.-Surgeon C. E. Riggs, ordered to the Naval Hospital, Philadelphia.

P. A. Surgeon R. T. Orvis, detached from the *Michigan*, and ordered to duty with Marine Detachment at Culebra.

A. A. Surgeon T. G. Foster, ordered to the *Michigan*.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended March 5, 1903:

Surgeon H. R. Carter, to proceed to Morgantown, W. Va., for special temporary duty.

Surgeon G. M. Guiteras, to report at Washington, D. C., for special temporary duty, February 28. To proceed to Eagle Pass, Texas, for special temporary duty, March 2.

A. A. Surgeon C. P. Wertenbaker, to proceed to El Paso, Texas, for special temporary duty.

P. A. Surgeon M. J. Rosenau, detailed to represent Service at meeting of Special Committee on Diphtheria Antitoxin at Philadelphia.

P. A. Surgeon J. H. Oakley, granted leave of absence for seven days from March 1, 1903.

Asst.-Surgeon C. E. Decker, granted fourteen days' extension of leave of absence on account of sickness from Feb. 20, 1903.

Asst.-Surgeon L. L. Lumsden, relieved from duty at San Francisco Quarantine Station, and directed to proceed to Los Angeles, Cal., and Phœnix, Ariz., for special temporary duty.

Asst.-Surgeon J. W. Kerr, directed to assume temporary command of the Service at New Orleans, Feb. 28, 1903.

Pharmacist R. H. Gibson, granted leave of absence for seven days under the provisions of Paragraph 190 of the Regulations.

BOARDS CONVENED.

Board convened at Washington, D. C., March 2, for the physical re-examination of Chief Engineer Geo. Maher, Revenue Cutter Service. Detail for the Board: Assistant Surgeon-General W. J. Pettus, chairman; Assistant Surgeon-General H. D. Geddings, recorder.

Board convened at Boston, March 9, for the physical re-examination of Lieut. B. H. Camden, Revenue Cutter Service. Detail for the Board: Surgeon R. M. Woodward, chairman; Asst.-Surgeon W. C. Rucker, recorder.

PROMOTIONS.

Asst.-Surgeon R. H. von Ezdorf, commissioned as passed asst.-surgeon, to rank as such from March 4.

Asst.-Surgeon J. F. Anderson, commissioned as passed asst.-surgeon, to rank as such from March 18.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended March 7, 1903:

SMALLPOX—UNITED STATES.

California: Berkeley, Feb. 18-25, 1 case; Los Angeles, Feb. 14-21, 3 cases; Sacramento, Jan. 25-Feb. 7, 4 cases; San Francisco, Feb. 15-22, 12 cases, 1 death.
Colorado: Denver, Feb. 7-21, 30 cases.
District of Columbia: Washington, Feb. 14-28, 6 cases, 1 death.
Illinois: Chicago, Feb. 21-28, 17 cases, 1 death.
Indiana: Elwood, Feb. 22-March 1, 3 cases; Evansville, Feb. 21-28, 4 cases; Indianapolis, Feb. 14-28, 57 cases, 16 deaths; Jeffersonville, Jan. 1-31, 1 case; Jeffersonville, Feb. 1-28, 5 cases.
Iowa: Davenport, Feb. 21-28, 4 cases.
Kansas: Douglas County, Jan. 1-31, 2 imported cases; Wichita, Feb. 21-28, 1 case, 1 death.
Kentucky: Lexington, Feb. 21-28, 1 case; Newport, Feb. 21-28, 1 case.
Louisiana: New Orleans, Feb. 21-28, 2 imported cases.
Maine: Biddeford, Feb. 21-28, 3 cases.
Massachusetts: Boston, Feb. 21-28, 2 cases; New Bedford, Feb. 21-28, 1 case; Newton, Feb. 21-28, 1 case.
Michigan: Grand Rapids, Feb. 21-28, 14 cases; Marquette, Feb. 21-28, 1 case; Menominee, Feb. 14-21, 1 case; Port Huron, Feb. 21-28, 5 cases.
Nebraska: Omaha, Feb. 21-28, 3 cases.
New Jersey: Camden, Feb. 21-28, 5 cases; Jersey City, Feb. 22-March 1, 3 cases.
New York: Buffalo, Feb. 21-28, 1 case; New York, Feb. 21-28, 4 cases; Yonkers, Feb. 20-27, 1 case.
Ohio: Cincinnati, Feb. 20-27, 11 cases, 1 death; Cleveland, Feb. 21-28, 7 cases, 2 deaths; Dayton, Feb. 21-28, 1 case; Hamilton, Feb. 21-28, 2 cases.
Pennsylvania: Altoona, Feb. 21-28, 6 cases imported; Dunmore, Feb. 21-28, 3 cases; Erie, Feb. 21-28, 5 cases; Johnstown, Feb. 21-28, 3 cases; McKeesport, Feb. 21-28, 2 cases; Norristown, Feb. 21-28, 1 case; Philadelphia, Feb. 21-28, 37 cases, 1 death; Pittsburg, Feb. 21-28, 19 cases, 6 deaths, 4 cases imported; Pottsville, Feb. 21-28, 4 cases.
South Carolina: Charleston, Feb. 21-28, 7 cases.
Tennessee: Johnson City, Feb. 21-28, 7 cases; Memphis, Feb. 21-28, 5 cases.
Utah: Salt Lake City, Feb. 14-28, 39 cases, 1 case imported.
Wisconsin: Green Bay, Feb. 22-March 1, 1 case; Milwaukee, Feb. 14-28, 11 cases.

SMALLPOX—FOREIGN.

Barbadoes: Jan. 31-Feb. 13, 9 cases, 1 death.
Belgium: Antwerp, Jan. 31-Feb. 7, 2 cases; Brussels, Jan. 31-Feb. 7, 6 deaths.
Canada: Winnipeg, Feb. 7-14, 1 case.
Canary Islands: Las Palmas, Jan. 24-Feb. 7, 69 cases, 2 deaths.
Ecuador: Guayaquil, Jan. 31-Feb. 7, 1 death.
France: Marseilles, Jan. 1-31, 37 deaths; Paris, Feb. 7-14, 1 death.
Great Britain: Birmingham, Feb. 7-14, 16 cases; Dublin, Feb. 7-14, 4 cases; Glasgow, Feb. 13-20, 1 case; Leeds, Feb. 7-14, 16 cases, 1 death; Leith, Jan. 31-Feb. 7, 1 case; Liverpool, Feb. 7-14, 6 deaths; London, Feb. 7-14, 1 case, 1 death; Nottingham, Feb. 7-14, 2 cases.
India: Bombay, Jan. 27-Feb. 3, 28 deaths; Calcutta, Jan. 24-31, 1 death.
Italy: Palermo, Jan. 31-Feb. 14, 11 cases.
Jamaica: Duan Vale, Feb. 1, present.
Japan: Kagawa Ken, Jan. 29, present; Yamaguchi Ken, Jan. 29, present.
Mexico: City of Mexico, Feb. 8-15, 6 cases, 2 deaths.
Netherlands: Amsterdam, Feb. 7-14, 3 cases.
Russia: Moscow, Jan. 24-Feb. 7, 9 cases, 3 deaths; Odessa, Jan. 18-25, 5 cases; St. Petersburg, Jan. 31-Feb. 7, 29 cases, 9 deaths; Warsaw, Jan. 31-Feb. 7, 1 death.
Turkey: Smyrna, Jan. 25-Feb. 1, 1 death.

YELLOW FEVER.

Colombia: Cartagena, Feb. 9-15, 2 deaths; Panama, Feb. 11-18, 2 cases.
Ecuador: Guayaquil, Jan. 31-Feb. 7, 21 deaths.
Cuba: Havana, Feb. 14-21, 1 case, 1 death, imported from steamship Esperanza from Progreso.
Mexico: Coatzacoalcos, Feb. 7-14, 1 case, 1 death.

CHOLERA.

India: Calcutta, Jan. 24-31, 53 cases.

PLAGUE—FOREIGN.

India: Bombay, Jan. 27-Feb. 3, 551 deaths; Calcutta, Jan. 24-31, 97 deaths; Karachi, Jan. 25-Feb. 1, 26 cases, 19 deaths.
Mexico: Mazatlan, Jan. 24-Feb. 7, 89 cases, 53 deaths.

IODIZED CATGUT.

NICHOLAS SENN, M.D., PH.D., LL.D.

PROFESSOR OF SURGERY, RUSH MEDICAL COLLEGE.

CHICAGO.

Absorbable suture and ligature material has held its place in surgery since Lister first introduced it into general practice. At times it has appeared as though it would become displaced by inabsorbable permanent material, but the general tendency at the present time seems to be in its favor. The improvements which have been made during the last decade in the sterilization of catgut and other absorbable animal sutures have contributed much in establishing and maintaining the confidence of surgeons in their use. There can be very little doubt that catgut will eventually render silk and metal obsolete as materials for buried sutures.

Nature abhors foreign material of all kinds in the living tissues. The ideal material for ligatures and sutures is one that is removable by absorption after it has accomplished the mechanical purposes for which it was employed. During my four months' tour through Europe and the Orient last summer I visited nearly a hundred hospitals and made special inquiries into the kind of suture material in use and the method of its preparation. Some surgeons relied on silk entirely, others used silk and catgut, and the smallest number relied on catgut exclusively. The methods of catgut sterilization were also found greatly at variance, as well as the manner of its preservation. The methods of Von Bergmann, Saul and Elsberg appeared to be most popular. The very fact that so many different methods of sterilization are still in vogue is the very best and most convincing proof that none of these have proved entirely satisfactory. The ideal sterilization of catgut consists in rendering the material not only absolutely sterile, but also mildly antiseptic without impairing its tensile strength and without destroying its durability on the one hand and interfering with its absorbability on the other.

The most recent method of catgut preparation is the one devised by Claudius.[1] The method consists in iodization of the raw material. The investigations made under the direction of his chief, Professor Bloch, were continued for more than a year, and every step taken was supervised by bacteriologic examinations. It was found that a 1 per cent. aqueous solution of iodin destroys the spores of the anthrax bacillus in eight days. The many experiments made by Claudius demonstrated that it requires seven days for the complete sterilization of catgut in this solution. He also ascertained that the iodized catgut is not only absolutely sterile, but at the same time strongly antiseptic. Imbedded in a solid nutrient medium infected with pyogenic microbes the iodin contained in the catgut inhibited the growth of germs some distance from the threads.

The following directions for the iodization are given: The commercial, raw catgut without any preliminary preparation is wound on a glass roll, two strings tied together to each roll. The disinfection is effected by immersion in a 1 per cent. solution of iodin. The solution is made by dissolving one part of iodin and one part of potassic iodid in one hundred parts of water. The solution is prepared by dissolving the potassic iodid in a small quantity of water, to which the iodin, finely powdered, is added and the concentrated solution is then diluted to 1 per cent. The solution and catgut are kept in a bottle with a wide mouth, which is closed with an accurately-fitting glass stopper. The date is written on the label of the bottle. After eight days the catgut is ready for use and is preserved in the same bottle and same solution. Before using the catgut it is immersed on the glass roll in a 3 per cent. solution of carbolic acid or an indifferent sterile fluid for the purpose of removing the iodin from the surface of the threads. The threads are cut in the carbolic acid solution as they are needed. The catgut not used during the operation is returned into the bottle, thus doing away with any unnecessary waste of material. Catgut thus prepared is pitch black, soft, pliable and almost as strong as silk. The knots are firm and not liable to slip.

According to the size of the catgut its removal by absorption takes place in from twelve to sixteen days, being a little more durable than alcohol catgut. It does not irritate the tissues, as the free iodin is soon converted into potassic and sodic iodid by chemical combinations formed with the salts of the tissue fluids.

The iodized catgut has been given an extensive practical test in the Frederick's Hospital, Copenhagen, and has been found eminently reliable. The ease of its preparation, the quality of the product, the results of bacteriologic investigations and what has been ascertained of its practical utility are sufficient inducements to give it a prompt and fair trial in practice. Since 1896 I have relied[2] exclusively on catgut sterilized by Hofmeister's method, but instead of preserving it in an alcoholic solution of bichlorid, I keep it ready for use in the following mixture: Absolute alcohol 950, glycerin 50, iodoform (finely pulverized) 100. The alcohol dissolves part of the iodoform. The catgut can be kept in this

1. M. Claudius: Eine Methode zur Sterilisirung und sterile Aufhebung von Katgut. Deutsche Zeitschrift für Chirurgie, Band lxiv, s. 489.

2. Ideal Catgut Sterilization. THE JOURNAL A. M. A., Dec. 12, 1896.

mixture for any length of time without losing its strength and without becoming brittle. In a very short time the color of the catgut becomes darker, and eventually pitch black. I always preferred old catgut to the recently prepared material, and have therefore been using iodized catgut for more than six years. I have used it to the exclusion of any other kind of catgut in the St. Joseph's Hospital, Presbyterian Hospital and the Surgical Clinic of Rush Medical College. Infection that could be traced to the catgut has been extremely rare. During the autumn quarter of Rush Medical College recently terminated only one case of deep-stitch abscess occurred. This was a case of large ventral hernia. Sutures of silver wire and catgut were employed in closing the parietal defect. It is more than probable that the catgut was contaminated after it was removed from the bottle.

With such uniform satisfactory results it was not without some hesitation that I abandoned the well-tried material for something new. I did so largely on account of the conviction I held that I had practically been using iodized catgut, and that I attributed the excellent results largely to the presence of iodoform and iodin in the material employed. In the paper in which I advocated sterilization of catgut by Hofmeister's method and its preservation in glycerin emulsion I stated:

Catgut to be safe should not only be absolutely sterile but should contain a sufficient quantity of an efficient antiseptic to render it unfit as a culture medium for pathogenic microbes. Most of the preserving solutions contain either corrosive sublimate or carbolic acid. Both of these antiseptics unduly irritate the tissues and increase the primary wound secretion, effects which can not fail in interfering, to a certain extent, with an ideal healing of a wound by primary intention.

The interesting experiments made by Lauenstein leave no doubt that it is almost next to impossible to render the field of operation absolutely aseptic by any of our present methods of disinfection. We are forced to admit that nearly every wound inflicted by the surgeon's knife contains some pathogenic microbes, notwithstanding that the strictest aseptic precautions may have been practiced. The experiments made by Ewald have also furnished positive proof that sterile catgut often contains a sufficient quantity of an unknown toxic substance which, by its destructive action upon the cells engaged in the reparative process, transforms them into pus corpuscles, resulting in the production of a limited aseptic suppuration and the formation of sterile pus. Undoubtedly many of the stitch abscesses which occur in the practice of painstaking aseptic surgeons have such an origin.

These experimental reseaches force on us the conclusion that catgut should not only be properly sterilized, but that it must be made sufficiently antiseptic to at least inhibit the growth, if not destroy the pyogenic microbes which enter the wound during the operation or which may reach it later through the circulation.

The investigations of Claudius have confirmed me in the belief that the iodin in the catgut is of far-reaching value in the prevention of stitch abscesses. The iodin suffices not only in effecting sterilization, but at the same time imparts to the catgut the necessary antiseptic qualities. The iodized catgut behaves in the living tissues like in the infected nutrient medium by inhibiting the growth of pyogenic microbes in its substance and immediate environment.

Iodin possesses marked antiseptic properties, as first shown by Liebig. Fibrin immersed in iodized water does not undergo putrefaction. Putrefaction in pus can be prevented and arrested by the addition of iodin. The addition of a few drops of iodin to fetid pus causes the odor to disappear promptly. The antiseptic properties of weak solutions of iodin in the treatment of suppurating wounds are very manifest. Iodin penetrates tissues, dead and living, quickly and deeply, its power of diffusion is great, qualities which, combined with its pronounced antiseptic properties, must entitle it to be considered the most desirable substance among the chemical agents employed for the sterilization and preservation of catgut.

We have used the iodized catgut prepared according to the directions of Claudius for a number of weeks in the surgical clinic of Rush Medical College, and the results so far have been entirely satisfactory. The raw material prepared in this country has been found more suitable for this method of sterilization than imported catgut from different sources. Some of the imported catgut was made brittle by immersion in the iodin solution the requisite length of time. If a large experience establishes the reliability of iodized catgut, then the method of catgut sterilization has been discovered which will recommend itself on account of its simplicity, more especially to the country practitioner and military surgeon. Experiments are now in progress in the surgical laboratory of Rush Medical College to determine the bactericidal power of iodin, and the results obtained will appear in a future communication.

THE ADMINISTRATION OF CALCIUM SALTS IN NEPHROLITHIASIS DUE TO URIC ACID CALCULI.

ALFRED C. CROFTAN, M.D.
PROFESSOR OF MEDICINE, POST-GRADUATE MEDICAL COLLEGE.
CHICAGO.

THE UNDERLYING FACTS AND PRINCIPLES.

Phosphoric acid forms three salts with sodium, as follows:

H_3PO_4, phosphoric acid.
NaH_2PO_4, mono-sodium-phosphate.
Na_2HPO_4, di-sodium-phosphate.
Na_3PO_4, tri-sodium-phosphate.

The mono- and the di-sodium phosphate normally occur in the urine. Uric acid is readily soluble in di-sodium phosphate, but it is not soluble in mono-sodium phosphate. The addition, in fact, of mono-sodium phosphate to a solution of uric acid in di-sodium phosphate will cause the precipitation of the uric acid.

It is clear, therefore, that the solubility of uric acid in the urine is enhanced by the presence of di-sodium phosphate and that the tendency to the formation of uric acid concretions increases in proportion to the amount of mono-sodium phosphate that is excreted through the kidneys.

It is also clear that any endeavor directed toward preventing the precipitation of uric acid in the urinary passages must be concerned with increasing the amount of di-sodium phosphate and decreasing the amount of mono-sodium phosphate.

The ideal would be to cause the complete disappearance from the urine of mono-phosphate and at the same time to produce the elimination through the kidneys of a quantity of di-phosphate sufficiently large to hold all the uric acid excreted in solution.

This can be done in two ways, viz., either, *First,* by decreasing the phosphoric acid in the blood entering the kidneys, or *Second,* by increasing the sodium in this blood; for the smaller the proportion of available acid to available base the greater the tendency to the formation of basic salts.

First. The decrease of phosphoric acid in the renal blood. The phosphoric acid of the blood is derived from three sources. First, phosphoric acid in the form of phosphates is ingested with the food. Second, phosphorus is contained in all albumins (chiefly the nucleins of the food); the oxidation processes going on in the organism convert this phosphorus into phosphoric acid. Third, phosphoric acid is similarly derived from the albumins (nucleins) of our own tissues. The phosphoric acid formed in the body is consequently derived both from the disassimilation of the food proteins and the catabolism of the proper tissues of the body.

The first two sources of phosphoric acid we can control directly by eliminating from the diet pabulum containing much phosphorus, as nuclein-containing foods, e. g., internal organs, young germinating plants, etc. (By limiting the ingestion of nuclein-containing foods we at the same time eliminate the chief source of uric acid.)

The third source of phosphoric acid we can only control indirectly, i. e., by removing from the blood and tissues, through other channels than the kidneys, the phosphoric acid that must inevitably be formed from the degradation of our own tissues.

Both the direct and indireet regulation of the phosphoric acid content of the blood can be achieved by the administration of calcium salts. For, in the first place, calcium forms insoluble salts with the alkaline phosphates contained in our normal food, and in this way prevents the absorption of this moiety into the blood. In the second place, calcium, owing to the great affinity it possesses for phosphoric acid, combines with the phosphoric acid encountered in the blood stream, and this proportion is subsequently eliminated in the form of calcium phosphate—not, however, through the kidneys, but in great part through the intestine. This is an important point, for in contradistinction to sodium, potassium and magnesium, all elements that are chiefly eliminated through the kidneys, calcium is principally (85 to 95 per cent.) eliminated through the bowel.

It will be seen, therefore, that calcium given by mouth can, first, prevent the entrance of preformed phosphoric acid (phosphates) from the food into the blood, and can, secondly, prevent the phosphoric acid formed in the organism from passing into the urine by causing its elimination through the intestine.

Second. The increase of the sodium in the renal blood. This object can be accomplished by the administration of sodium salts by mouth; but this is bad practice. It is dangerous for various reasons to render the urine continuously alkaline. And this occurs if doses of sodium salts are exhibited large enough to convert all the mono-phosphate of the urine into di-phosphate. Normal urine is faintly acid, and it should be kept so. Calcium salts given in very large doses never render the urine alkaline.

Whereas, therefore, the administration of large doses of sodium salts for long periods of time may be indicated on theoretical grounds, it is counter-indicated on empirical grounds. First, because it renders the urine alkaline and thus favors the deposit of concretions other than uric acid stones; second, because it exercises a deleterious effect on gastric digestion; third, because it is not without effect on the corpuscular elements of the blood; fourth, because it is superfluous, as calcium salts by decreasing the phosphoric acid of the urine thereby cause a relative increase of the sodium (and of the sodium di-phosphate) without at the same time rendering the urine alkaline.

To summarize, therefore:

1. The uric acid of the urine is held in solution by di-sodium phosphate and is precipitated (salted out) by mono-sodium phosphate.

2. For the prevention of uratic calculi the increase of di-phosphate and the decrease of mono-phosphate is, therefore, a desideratum. This object can be accomplished either by decreasing the phosphoric acid or by increasing the sodium of the urine.

3. Calcium salts produce the desired effect by decreasing the excretion of phosphoric acid through the kidneys.

a By binding the preformed phosphates of the food and preventing their absorption.

b By binding the phosphates of the blood and causing their elimination through the bowel.

4. The administration of sodium salts that can also produce an increase of the di-phosphate and a corresponding decrease of the mono-phosphate is to be condemned, chiefly because sufficiently large doses render the urine permanently alkaline. And this deleterious effect is not produced by the exhibition of calcium salts.

DOSE AND ADMINISTRATION.

The best calcium preparation is the carbonate; this may be given in doses of fifteen to twenty grains three times a day. More may be given with impunity. Von Noorden advises as much as fifteen grams a day, and claims never to have seen any bad effects even after months of this treatment. It is necessary to individualize—the smallest efficient quantity of any drug is always the best dose. The urinary calcium, phosphorus and uric acid excretion should be determined in the beginning (the patient being on a fairly constant, nuclein-free diet) and the dosage regulated accordingly.

A more convenient form of administering calcium and one that is preferred by most patients, particularly if the treatment is to be carried out indefinitely, is to give calcium in the form of natural mineral waters or as an addition to some pure water. Among the better known European mineral waters Contrexéville, Wildungen and Fachingen contain the largest proportion of calcium salts. Among domestic waters the choice is difficult. The exploiters of the majority of them make such blatant and extravagant claims in regard to wonder cures that it is not safe to place any reliance on this essentially commercial propaganda. Personally, I prefer adding the necessary amount of calcium salt or lime water to some pure water; for the "curative" value of most natural and artificial mineral waters depends more on the water than on the salts they incorporate. Abundant water drinking is in itself indicated in urolithiasis, as any dilution of the urine must needs counteract the tendency to urate concretions. That the diet should in addition be so regulated as to lead to the smallest possible excretion of uric acid need hardly be emphasized.[1]

THE DIAGNOSIS OF URIC ACID CALCULI.

It is important to determine that the calculi or the "gravel" passed are really composed of uric acid or urates and not of other possible substances. The following method is rapid and easy of execution.

The concretions are finely powdered. A portion is treated with dilute cold hydrochloric acid in a test tube; if effervescence occurs the concretion contains carbonates, and if it dissolves it is not a uric acid stone. If

1. See my article on "The Modern Basis of Dietetic Treatment in the Uric Acid Diathesis," N. Y. Med. Jour., Nov. 1, 1902.

nothing or only very little of the material goes into solution, the residue is treated with a large quantity of warm dilute HCl. Any residue is presumably uric acid for the sulphates and oxalates of lime, the phosphates, cystin and xanthin all go into solution. The residue is filtered off, dried and heated on a piece of platinum foil; a distinct odor of bitter almonds (HCN) speaks for uric acid. Finally, the murexid test may be performed as follows, in order to render the diagnosis certain. A small quantity of the material is dissolved in nitric acid and a few drops of the solution evaporated in a porcelain dish; the residue should be red—it should turn purple when touched with a drop of ammonia, and reddish-blue with a drop of potassium- or sodium-hydrate.

RESULTS.

I report four cases; they present no clinical features of sufficient intrinsic interest to merit chronicling in detail. The only noticeable fact is that all four were advised by me several years ago to use calcium salts continuously; that all four were lost sight of for periods varying from two and a half to four years, and that all four recently again came under observation for other causes without having suffered a recurrence of their attacks of renal colic during the whole intervening time. Several other cases I have lost track of, but hope to rediscover.

Von Noorden, who first advocated the use of calcium salts in nephrolithiasis, reports only two occurrences of renal colic among twenty-one cases; in one patient an attack occurred a few days after beginning the treatment; in another patient who had suffered from severe attacks every few weeks, an attack developed nine months after the treatment was begun, and not again thereafter.

The good results obtained in my four cases and the statistics of Von Noorden lead me to believe that the treatment of uratic nephrolithiasis by the continuous exhibition of calcium salts is efficacious and deserving of extended trial.

100 State Street.

GLIOMA RETINÆ WITH REPORT OF FIVE CASES.*

CHRISTIAN R. HOLMES, M.D.
CINCINNATI, OHIO.

Glioma is a disease limited to childhood, and we may consider it the only true neoplasm developing in the retina. Its synonyms are: "Neuro-epithelioma" (Wintersteiner), "gliosarcoma" (Virchow), "glio-angiosarcoma" and "tubular gliosarcoma" (De Gama Pinto).

H. Knapp, in 1867, appears to have been the first to give an accurate and thoroughly scientific description of this class of tumors. In 1868 appeared Hirschberg's classical work on this subject, with a report of 77 cases collected from different sources. Virchow believed the cells of this class of tumors to be derived from the supporting fibers of the retina (the glia), and hence gave it the name of glioma retinæ.

Iwanhoff, in 1869, described the structure of the glioma as follows: "The larger nodules are always very vascular, with a characteristic arrangement of the cells which are concentrically grouped around the blood vessels. On section the whole nodule appears to consist of closely arranged cell rings whose central spaces are filled with red blood corpuscles."

Wintersteiner has tabulated 500 cases from all sources, 31 of these being his own, which had been very thoroughly studied microscopically. The same author has tabulated the following cases, in which the origin of the gliomatous growth could positively be traced to one or more of the retinal layers with the following results:

(a)	Origin in layer of optic nerve fibers	5 cases
	Origin in inner nuclear layer	19 cases
	Origin in any of the inner layers of retina	12 cases
	Total	36 cases
(b)	Origin in outer nuclear layer	9 cases
	Origin in outer layers of retina	3 cases
	Total	12 cases

From this we will observe that the origin is three times more frequent in the inner than in the outer layers. We must remember that the origin is not limited to one layer of the retina, but may spring from several layers in the same case. It has been observed that gliomata have their origin four times more frequently from the posterior than from the anterior half of the globe. The same author accepts Cohnheim's theory that tumors have their origin in the masses of embryonic cells which are at times left over in the building of the normal structure, these cells remaining dormant in their embryonic state until at some later period they may take on an active and perverted growth. Prof. Schöbl, who has observed a very large number of this class of tumors, concludes that glioma may start from the supporting fibers of any of the layers of the retina, but mostly from the inner nuclear layer. In this layer Da Gama Pinto found that the nuclei were mostly in process of division with karyokinetic figures. That glioma is a form of tumor independent of and different from sarcoma, was first doubted by Cornil and Ranvier; later they were termed small round-celled sarcomata by Delafield, and Nagel agreed in this opinion. From Virchow's standpoint the supporting tissue of the retina can not be considered identical with common connective tissue, and from the standpoint of Klebs the gliomata are derived even from a different germinal layer than that from which the sarcomata arise. The clinical picture of glioma also is so well defined that to confound it with sarcoma is against good judgment.

Becker thinks that there is a sufficient number of mesoderm cells in the blood cells to give rise to sarcomata. To this it must be answered that their origin from the granules of the nuclear layer directly, especially of the inner one, can be observed, and that processes of division can be seen there, as Da Gama Pinto, Schöbl and others have witnessed, and that not a single observer has found a glioma starting from a retinal blood vessel, while with sarcomata this is nothing rare.

The most frequent mixed tumor of this kind is gliosarcoma (Virchow). When spreading into the choroid and sclera and beyond the eye, gliomata may sometimes change their character in that their cells grow larger, up to 15 microns, while their nuclei remain comparatively small—6 to 10 microns; that is, the protoplasm is increased, or, in other words, the cells assume the character of small round-celled sarcoma. Berthold was the first who asserted that gliomata may assume a sarcomatous character, after having spread into the choroid, and that this membrane, irritated by the entering of the glioma cells, furnishes the sarcomatous elements. In a reverse way it may occur that sarcomata of the choroid take on a gliomatous character. This, perhaps, explains Von Graefe's two observations of gliomas in adults.

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. Frank Allport, H. V. Würdemann and J. A. Lippincott.

Prof. Schöbl's remarkable case of glio-fibro-sarco-myo-angioma confirms the statement that the character of the tumor often depends on whether or not it has invaded other tissues. In this case, the pure retinal glioma, when it spread into the sclera, produced proliferation with the formation of glio-fibroma; when the glioma cells spread into the orbital tissue they caused a proliferation in this locality, and sarcomatous (round and later spindle) cells were formed; and thus a glio-fibro-sarcoma resulted. The same process was repeated with the unstriped muscular tissue of the blood vessels, and thus the tumor formed a glio-fibro-sarco-myo-angioma.

Greef has examined fresh gliomata by the impregnation methods of Golgi and Cajal. By the latter method he succeeded in demonstrating the presence of differently shaped cells in retinal glioma. He found numerous oval and star-shaped cells with free offshoots which were undoubtedly true neuroglia cells and the original cells of the tumor. From Greef's investigations, it appears certain that gliomata are not neoplasms of sarcomatous nature, since impregnation of the cells after Cajal's method could not take place. It is believed by some authors that neuro-epithelioma of the retina is always congenital, or at least that a predisposition exists through some disturbance in the process of development.

Glioma spreads in the retinal structure: 1, by enlargement of a single or the confluence of several smaller nodules, and 2, by metastasis within the retina.

The growth of the primary nodules takes place through division and multiplication of the cells next to the blood-vessels, whereby the older cells are constantly crowded farther back toward the periphery and become necrotic for want of nutrition.

The growth spreads in three ways: 1, through the inter-lamellar spaces; 2, through the lymph channels, and 3, through the blood-vessels.

It is characteristic of the development of glioma that the growth not alone displaces other structures by pressure but replaces them by neoplastic tissue. With the destruction and transformation of the retina by the rapidly developing gliomatous tissue come retinal detachment and an extension of the process to other structures, the choroid being generally and naturally the first to be involved. Beyond the retina and the choroid the extension of the neuro-epithelioma takes place most readily along the optic nerve, the cancer tissue replacing the nerve bundles and finally extending to and involving the chiasm and surrounding structures. Secondary tumors have been found in nearly all of the organs and even the bony structures are frequently involved.

In the second and third stages the growth replaces the orbital tissue, extending to and destroying the periosteum and bone by erosion.

The diagnosis between gliomata and other tumors is easily made, but the differentiation of the pseudo-glioma is fraught with many difficulties, but only when the disease is well advanced. We must differentiate from: 1, detachment or cysts of the retina; 2, tumors of the choroid and ciliary region; 3, masses of inflammatory exudate in the vitreous (pseudo-glioma), and 4, the combination of true glioma with any of the above.

The greatest difficulty in making a correct diagnosis occurs when the cornea, aqueous or lens have undergone such changes as to prevent inspection of the interior of the globe, cataract being the most frequent condition encountered. As a rule, we may state that inflammatory exudates into the vitreous give a yellowish reflex, with a metallic luster and smooth surface, while the color of glioma may be a light yellow, reddish or greenish-yellow and the growth is nodular.

The diagnosis may be complicated further by the formation of a post-inflammatory membrane or exudate upon the hyaloid membrane directly behind the lens, by chronic inflammation and fibrinous exudate into the vitreous, or by acute suppurative hyalitis. From detachment of the retina it should be readily differentiated by a careful ophthalmoscopic examination, and from tumors of the choroid by the fact that they are nearly all pigmented. Leucosarcoma of the choroid is rare and its growth is dissimilar to that of gliomata. It develops as a solitary half-round mass over which the retina may be atrophied, but does not form reduplications and thickened masses.

That there is often great difficulty in making a differential diagnosis between the true and the pseudo-glioma, is proved by the fact that Raab found in the collection of Otto Becker of Heidelberg twenty eyes that had been enucleated by various expert diagnosticians, after the diagnosis of glioma retinæ had been made, and yet in 25 per cent. of these no gliomatous or cancerous tissue was present, but only inflammatory changes in the uveal tract. Treacher-Collins reports that out of 1020 eyes removed in Moorfield Hospital, London, from 1888 to 1892, the diagnosis of glioma had been made in 24 cases, and yet microscopic examination revealed that 7 of these were pseudo-glioma.

Fortunately, neuro-epithelioma of the retina is rare. Even in the largest clinics, six months to a year may pass without a child with glioma being presented. Twenty-two of the great clinics of the world reporting 498,057 patients, record 203 cases of glioma—one twenty-fifth of 1 per cent.—or one case of glioma out of every 2500 cases of diseases of the eye. But after reading the reports of Raab and Treacher-Collins, mentioned above, we are justified in concluding that no doubt many of these were cases of pseudo-glioma.

The disease is absolutely limited to childhood and is often well advanced at birth. The combined results of investigation by leading oculists of the world seem to prove conclusively that when glioma is reported as a primary growth in an individual over 16 years of age it is a mistaken diagnosis. Out of 467 cases, the growth was developed at birth in 34 cases to such an extent as to present the amaurotic cat's eye. Ophthalmoscopic examination would have shown a much larger number. Including these congenital cases, there developed during the first three years of life, 314 out of a total of 467 cases, or 67 per cent.

The percentage of involvement of both eyes is very large; out of 87 cases it occurred 16 times at birth, or in 18.4 per cent. Deducting these congenital cases from the 87 cases, it was found that both eyes were involved 65 times out of 71 cases during the first three years of life.

It is of interest to remember that the second eye appears never to have been found to become involved by an extension of the disease along the optic nerve and through the chiasm from the first eye. Where both eyes are affected, the disease always develops independently in each eye.

The disease may extend backward along the optic nerve to the chiasm, involving adjacent structures and causing death, but it has not been known to travel from the chiasm peripherally along the nerve of the sound eye; blindness of the non-affected eye due to atrophy may, however, result because of the destruction of the nerve fibers in the chiasm.

The influence of heredity has not been demonstrated; as yet we know of no case in which an individual who had an eye removed in childhood for glioma, has transmitted the disease to his offspring. There are, however, many cases on record where several members of one family have been affected, just as at times we find congenital cataract in some or all of the children of one family, where the parents are closely related. I have been unable to find whether there was consanguinity between the parents of the patients about to be cited.

Lerche, St. Petersburg, 1821, observed a family of 7 children, 4 of whom died from glioma; Sichel, in 1852, 4 cases in one family; Calderini, in 1867, 3 cases in one family; Knapp and Thompson, in 1874, 5 cases in one family; MacGregor, in 1885, 3 cases in one family, and Flexner, in 1871, 3 cases in one family. Wilson, in 1872, exhibited before the Pathological Society of Dublin, the photographs of 8 children of one family, four of whom had died from glioma and the remaining four being also afflicted with the same disease.

The disease may be divided into three stages of development:

1. Period of intra-ocular growth, without increased tension or inflammatory symptoms.
2. Glaucomatous or inflammatory period, which ends with rupture of the globe.
3. The period of extra-ocular growth and metastasis.

In some cases there is temporary arrest and even retrograde change, such as phthisis bulbi after rupture or violent inflammatory reaction of the globe, the temporary arrest being probably due to destruction of the vessels of nutrition with degeneration of the glioma cells as a result of the suppurative process.

Death may result from:

1. Involvement of the brain.
2. Cachexia.
3. Pressure of the growth on the medulla oblongata.
4. Suffocation from extension of growth into the pharynx and larynx.
5. Pyemia or septicemia, with metastatic abscesses.

The duration of life when there is no surgical interference varies greatly, but from a few months to three years is the average. A few cases have been reported where the first period lasted five years from the time the disease was first discovered. The average duration of the second stage is from 2 to 21 months, while the third stage from the rupture of the cornea to the fatal termination is the shortest, varying from two weeks to one year, with an average of three months.

If there is no return in two years after enucleation the case may be regarded as cured so far as that side is concerned, but we must remember that the disease may occur in the other eye a considerable period after the first eye becomes affected, and we must then regard it as an independent attack in the same patient and not a recurrence of the primary growth.

The only treatment that can be considered as offering any chance of saving life is removal of the affected eye, with as much as possible of the optic nerve, at the earliest possible moment during the first stage. In operations undertaken during the second stage, before the rupture of the cornea, the chances of success are very slight, since the infection has often extended outside of the globe through the veins or lymph channels. But even then it is our duty to operate, and exenteration of the orbit should be added to the enucleation of the eye, if we hope to arrest the disease. In this stage I regard the use of pastes far superior to the use of cutting instruments, because the liability of opening up new avenues of infection is much greater in the latter method.

When the case has once entered the third stage the rule is that, no matter how thoroughly exenteration is performed, there is always recurrence within a few weeks, and operation in this stage is only justifiable in order to afford temporary relief.

With the advent of serum-therapy it was hoped that this mode of treatment might be of service, and Nieden reported his observations upon this method at the meeting of the Ophthalmological Society at Heidelberg in 1896. The cancer serum was injected in a case of recurrent glioma. At first there appeared to be an arrest of the growth, but it soon broke forth with greater fury than before, and went on speedily to a fatal termination.

Shall we advise enucleation if both eyes are affected? Since cases of undoubted glioma—as proved by the microscope—have been cured after double enucleation, and as the disease springs from a separate and independent focus in each eye, we should answer this question in the affirmative, and urge the operation if the disease has not progressed beyond the first or second stage in either eye. For if life is saved, blindness to a child at this period is not a barrier to its acquiring an education and becoming a useful and independent citizen.

CASE 1.—Baby M., female, white, aged 2 years, was first seen by me Feb. 7, 1894. Child was well-nourished and its general health good. Left eye normal; right pupil dilated, which caused the mother to seek consultation. External appearance of globe normal. The pupil appeared the normal black color. Tension normal. Ophthalmoscopic examination revealed that the dioptric media was clear, but there was a flat, yellowish, nodular mass to the outer side of disc; retina was intact outside of the affected area. A diagnosis of glioma retinæ was made, immediate enucleation advised, and the danger of delay fully explained to the mother. The family physician was informed of my opinion. He examined the eye superficially and said he could see nothing wrong, advised against the operation, and gave the mother little sugar-pills for the child.

May 3, nearly three months later, the mother returned with the child. It was emaciated, exhausted and fretful, frequently crying out in pain. The case was now well advanced into the second stage. Globe injected, tension +2, anterior chamber obliterated, pupillary area filled with a yellowish mass, slightly irregular, with a few fine vessels seen upon the surface. The family physician had now withdrawn his objection to operation. Left eye was still normal.

In order to give the child its only chance, and to relieve the suffering caused by the glaucomatous eye, I enucleated the globe and also removed a considerable piece of the optic nerve. Under similar conditions I should now make exenteration of the orbit. The operation was followed by marked improvement in the child's general condition, but on October 8, about five months after the operation, the mother returned with the child stating that it had vomited frequently during the previous week. Its appetite was poor, but it slept well. No other general symptoms were present. The orbital cavity was filled with a hard mass which did not appear to be attached to the bony walls, but was movable; the new growth appeared to spring from the optic nerve-end, which formed its pedicle. The tumor was removed to the very apex of the orbit and, as surmised, it sprang from that part of the optic nerve which had not been removed at the first operation. As I considered the case beyond hope, I did not wish to cause the child additional and useless suffering by the use of cautery or pastes.

The growth promptly recurred and soon developed into a large protruding mass. The child suffered most terrible agonies unless kept under the influence of opiates, 1½ grs. of morphia being administered hypodermatically every 4 or 6 hours.

The child died on Feb. 26, 1895. (Figs. 1 and 2 are sketches made after death, showing the appearance of the growth.)

Postmortem Notes.—Child greatly emaciated. Tumor 12 inches in circumference at the base, projecting from the right orbit about 4 inches. In shape, the tumor had much the appearance of a small cocoanut, and it was of a dark reddish color. The projecting surface was broken down in places and covered with nodules. The growth involved the bony structure and extended from the roots of the hair almost to the alveolar process. The meninges at the base of the right side and a portion of the brain, together with the optic nerve, were extensively invaded by the cancerous tissue which was partly ne-

Fig. 1.—Case 1. Recurrent growth one year after neoplasm was first discovered ophthalmoscopically. Nine months after enucleation and five months after removing recurrent growth and all of optic nerve to apex of orbit.

crotic. The meninges and brain of the left side, together with the left eye, appeared normal.

Microscopic Report of Globe.—Dr. Louis Stricker reports as follows: Unfortunately, the eye was cut through the equatorial region; hence, no complete sections of the entire globe could be made. Both halves were filled with a new growth, showing on its surface minute red spots—large ves-

Fig. 2.—Side view of Fig. 1.

sels—and around these areas of a greenish color, whereas, at a distance from these the surface was white. The general contour of the globe was retained and at no point had the tumor perforated the sclera. The optic nerve, especially its nasal half, showed decided thickening. The anterior half of the globe was also filled with the tumor mass, and entirely hid from view the lens and ciliary body.

The specimen was carefully hardened in Mueller's fluid for 5 months, then washed out and gradually hardened in alcohol, finally imbedded in celloidin, and then cut in sections.

Without the use of a lens, the sections disclose that the optic nerve is infiltrated with the tumor up to the point of excision, necessarily having left behind some part of the new growth.

A general view of a section of the globe discloses a complete obliteration of the retina, not a vestige of its anatomic structure remaining, except here and there a few retinal pigment cells—a most widespread involvement of the choroid, which in many places is thickened to many times its normal size, and likewise, a complete involvement of the optic nerve, with total obliteration of nerve fibers.

All the sections disclosed a very marked involvement of the choroid. Anteriorly, for a very short distance, the choroid was found normal, but as it was followed around toward the optic nerve, its involvement in the tumor mass at once became apparent, and nodules begin to appear, until large areas are encountered completely infiltrated with round cells containing large nuclei. The stroma pigment cells of the choroid have entirely disappeared, but the vitreous lamella is in many places sharply outlined, giving the line of separation from the retina. In some places, however, the vitreous lamella has been eroded, and thus a point either of entrance or exit has been given for the tumor to invade this space between the choroid and the retinal layer of pigment cells which here and there exist and act as a barrier to invasion. At one point in the tumor the continuity of this vitreous lamella is broken, and here a distinct point of communication between choroid and interior of globe exists. In one section was found an enormous vessel extending directly from the choroid out into the tumor mass. The retinal detachment extended as far as the ora serrata, at this point the cystic degenerated retina can be followed forward for a short space, to be entirely obliterated in lobules of tumor.

The portions of the tumor confined strictly to the choroid are made up of round cells, which take the stain deeply, and to an equal degree, and though this is permeated by blood-vessels, they do not seem particularly more numerous or larger than usually encountered in the normal choroid. As soon, however, as the tumor is followed beyond the strict confines of the choroid, the vessels are much more numerous, widely dilated, some more than twice the size of the normal arteria centralis retinæ, and filled with blood cells. Around each one of the vessels the round cells of the tumor are closely pressed together, so that they often take on a polyhedral shape. They take the stain very deeply, whereas, at a distance, much less so, so that the tumor has a peculiar spotted or lobulated appearance. Nowhere did I find places where the tumor cells formed the walls of the vessels, but everywhere there are large vessels with thickened and distinctive vessel walls, showing the endothelial cells lining the vessel wall, the intima of the vessel, and around these grouped the cells of the tumor.

The choroid is distinctly and sharply demarcated from the optic nerve by connective tissue fibers. The fibers of the lamina cribrosa are especially sharply defined and pushed backward by the tumor, which has encroached on the nerve head, and finally invaded and thoroughly destroyed its fibers. Nevertheless, the line of demarcation between the choroid and nerve head is very sharply defined. The optic nerve itself is greatly thickened, its nerve fibers being entirely obliterated by the extreme infiltration. Both artery and vein intensely dilated and filled with blood cells. To the side of the artery this tissue is one mass of round cells, and all along the nerve sheath are new-formed and widely dilated blood-vessels. The lymph space is obliterated, due in part to the infiltration and swelling of the nerve and in part to the infiltration of the arachnoidal sheath and space, and also of the dural sheath (Figs. 3 and 4). The side nearest the vein is likewise infiltrated with round cells, as is also its dural sheath. These conditions exist to the very end of the nerve. In some of the sections the arteria centralis retinæ can be followed outward directly into the tumor mass, leaving no doubt that many of the large vessels permeating the tumor take their origin from the large central vessels.

The retina has been partly destroyed.

The sections of the anterior half of the globe (Fig. 5) show the retina detached to the ora serrata, from which point it was pushed anteriorly toward the lens, from both sides coming up close to the lens and then going backward toward the nerve head—a typical, total, umbrella detachment. In the triangular space between the lens and receding retinal framework are the connective tissue fibers of the vitreous. All the anterior sections of the choroid show this to be infiltrated. The ciliary body and its processes are atrophied, doubtless from pressure, and they likewise show slight infiltration.

The lens has not been affected and is perfectly normal, although the tumor mass with large blood-vessels is pressed

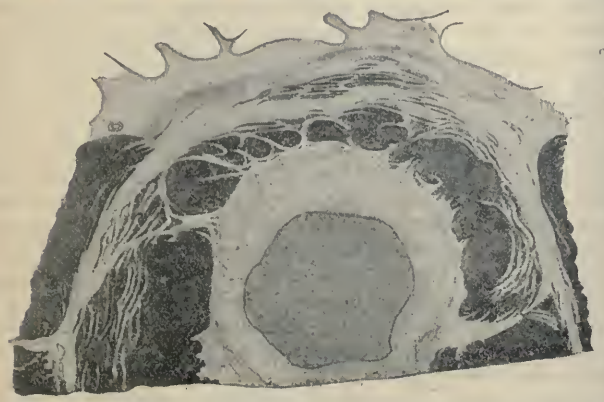

Fig. 3.—Section of optic nerve. The nerve fibers totally destroyed; also notice enormous thickening of the inner sheath, and infiltration of the subdural and subarachnoidal spaces with the tumor mass. (After Wintersteiner.)

up against its posterior surface. The lens shows the peculiar bulged edges always found in cases of tumor in the eyeball. On one side the tumor cells have worked their way through Petit's canal into the posterior chamber and forced the iris forward on that side, so as to produce a wide curvature, and a deepening of the posterior chamber. Some of the cells have found their way into the filtrating angle of the anterior chamber, which is not occluded.

The iris is atrophic, and near its insertion shows some widely dilated vessels. The cornea is normal. The sclera

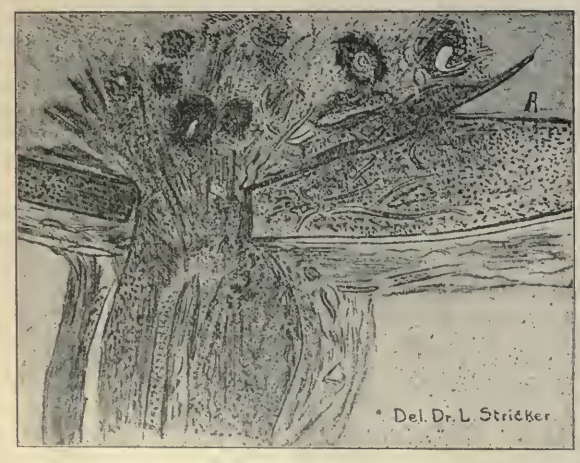

Fig. 4.—Case 1.—Showing new growth and infiltration of optic nerve.

is attenuated owing to long intra-ocular pressure. Posteriorly, near the optic nerve entrance, it is traversed by vessels showing a large increase of nuclei in their vicinity.

This tumor is exceedingly vascular, the large size of the vessels being a prominent factor. Part of the tumor seems to be strictly confined to the choroid, and by a pedicle extends inward into the vitreous space, which is completely filled by the tumor mass. The large mass occupying the vitreous space has a characteristic appearance on section of deeply-stained portions around the vessels, and is less stained at more remote points, this being a result of removal of portions of the tumor from nutrition derived from the vessels. The growth of the tumor is likewise dependent on the growth of the vessels, around which the cells of the tumor arrange themselves, thus producing the alveolar or tubular form of tumor. The cells forming the tumor are all of the round-celled, non-pigmented variety.

The entire retina has been obliterated, save the cystic framework close to the ora serrata. That which originally—taking into consideration the age of the patient, 3 years—may have been a glioma, on spreading to the choroid—either by continuity of tissue or by direct introduction of cells of the tumor through the venous circulation—aroused this to excessive cellular activity, and so introduced the sarcomatous element which has completely masked the original picture, thus producing the glio-sarcoma of Virchow.

From this report the question might arise, whether or not this was a case of glioma, but the age of the patient, the rapidity of the growth, and above all, the early clinical picture, leave not the slightest doubt that the tumor primarily was a glioma, eventually assuming the sarcomatous type.*

Dr. H. J. Whitacre reported as follows upon the recurrent growth springing from the optic nerve: The structure is that of small round cells in definite connection with a fibrous intercellular substance. The blood vessels are poorly formed and pigment granules are

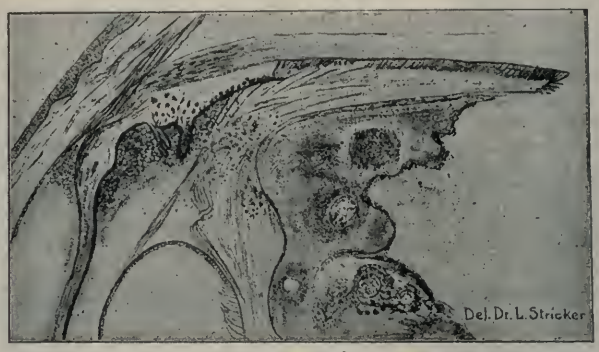

Fig. 5.—Section from anterior half of the globe, showing detached retina, atrophy of ciliary body and new growth pressing on the posterior surface of lens, which had remained perfectly transparent.

found in many parts. The tumor is a small round-celled sarcoma.

CASE 2.—Baby R. E., aged 5 months, was brought to me Dec. 29, 1897. The child was well developed and nourished. Three weeks ago the parents noticed that the pupil of the right eye was dilated, and had a "silvery appearance which made the eye look dull." Dr. W. F. Shepherd was consulted, and promptly referred the case for consultation. The globe was congested; T.=+I; cornea clear; anterior chamber obliterated; lens and iris in contact with cornea; pupillary space filled with a mass of a reddish gray color, the surface being unusually vascular, the disease having advanced to the second stage. The appearance of the growth when examined under a strong light, gives a peculiar reflex not unlike a fire opal. Ophthalmoscopic examination of the left eye under mydriasis was negative. The child was admitted to my hospital; the same day enucleation with extensive resection of the optic nerve performed, and the specimen given to Dr. H. J. Whitacre for microscopic examination. The following is his report:

The specimen received was a complete right eye, which was placed in a 4 per cent. solution of formol for four days, and the hardening completed in 95 per cent. alcohol.

* The report, however, shows how very important it is to pull the globe well forward when enucleating, and to cut the nerve at the very apex of the orbit so that if possible, we may extend beyond that part of the nerve which may be infiltrated with cancer cells. In this case I resected the nerve far back, but the disease had extended further. Still, by subjecting the nerve to extra stretching, I might have secured more.

A sagittal section of the hardened specimen presented the appearance shown by the photograph (Fig. 6), and demonstrates a globular tumor occupying mainly the temporal half of the vitreous chamber. Posteriorly, the nasal half shows a pedicle attached to the point of entrance of the optic nerve. Anteriorly, the tumor presses against the posterior surface of the lens, and on each side of the detached retina can be seen a thin membrane extending from the tumor to the choroid.

The tumor, when half hardened, was very soft, and must have been almost gelatinous in its fresh state. Sections of the tumor were made with difficulty because of the multiple

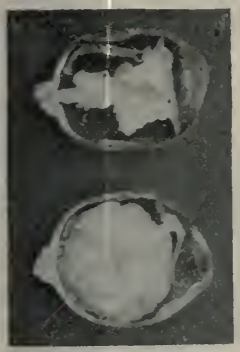

Fig. 6.—Case 2. Right eye, removed first. No recurrence three years and eight months afterwards.

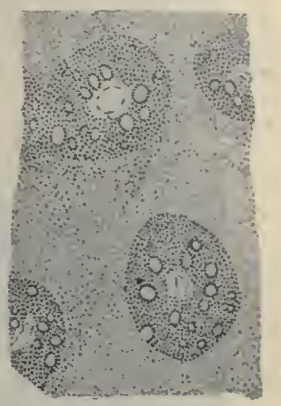

Fig. 7.—Neuroepithelial nests or "rosettes" surrounding a central blood vessel. (After Wintersteiner.)

points of calcareous degeneration which dulled the knife and tore the sections. In general arrangement the tumor is made up of bands and circles of cells arranged regularly about the central opening (Fig. 7). The appearance is that of a vascular tumor with the cells concentrically arranged around the central vessel.

By higher magnification the lumen of this central vessel looks like the acinus of a gland surrounded by high columnar

Fig. 8.—Photomicrograph showing the cells concentrically arranged around central vessels, forming "rosettes."

cells (Fig. 8); the other cells of the area have similar characteristics because of their origin by proliferation from these central cells. These central openings may be either lymph or blood-vessels, and it would be difficult to say which they are. Yet it would seem that they are blood-vessels because of the presence of blood cells within their lumen.

In Fig. 9 is shown a section of the optic nerve removed with the globe.

The manner in which the glioma developed from the inner-nuclear layer is beautifully demonstrated in Fig. 10, taken from Case 2; and also shown in Fig. 11, copied from Wintersteiner; the relative size and location of this nodule is shown in Fig. 12. In this illustration we see three distinct gliomatous nodules in the totally detached retina; the one shown in Fig. 11 is seen as a minute pin-head swelling near the posterior surface of the lens. The second growth is in the upper and posterior

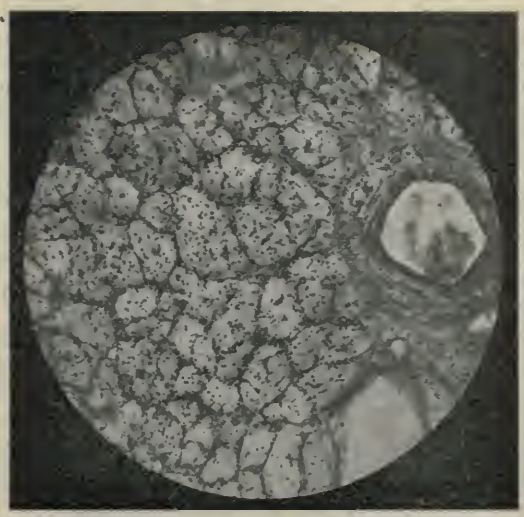

Fig. 9.—Case 2. Section of right optic nerve, removed with the globe. Nerve is normal, and there was no recurrence.

portion, in shape resembling the lens, but smaller. While nearly the whole lower half of the vitreous chamber is filled with the third nodule.

Re-examination.—April 26, 1898. The patient was re-examined and the following note is found in the record: "Right orbital cavity has healed perfectly; no evidence whatever of any return of the growth. Left Eye—Pupil, tension and general appearance, normal. Ophthalmoscopic examination negative." In January, 1900, I sent a communication to the

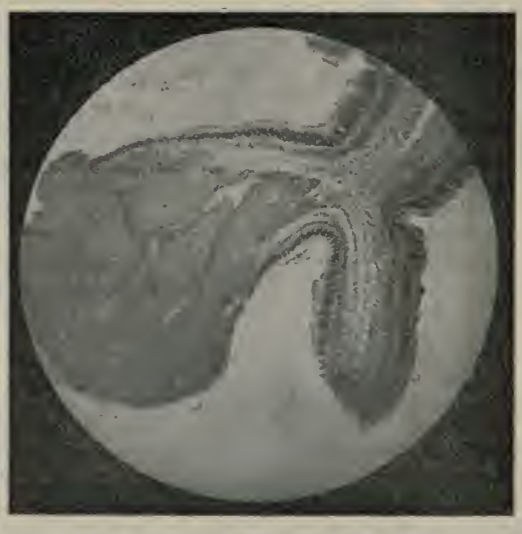

Fig. 10.—Glioma from right eye of Case 2, showing how the new growth sprang from the inner nuclear layer of retina.

parents asking if the child was still living and if so to bring it to the office, which they did February 7. Child in excellent physical condition; the right orbit from which the eye had been removed 2 years and 2 months before, was in perfect condition, the conjunctival sac smooth and pale. The left eye appeared normal; the pupil was dilated with a mydriatic, a careful ophthalmoscopic examination made, and the fundus found normal.

On March 7 the mother returned, bringing another child who had complained of its eyes, as she feared that a similar growth

might be developed in this child; this, however, proved not to be the case. I made another examination of the baby which she had brought with her and found to my great surprise that there was a small, whitish-yellow, irregular patch, appearing as a slight thickening of the retina, its edges not being sharply defined. It had an area of about one-half the diameter of the disc and was located outwards from the same about two diameters. The mother was told to bring the child again in one week, when it was found that the infiltration had

Fig. 11.—Miliary nodule (glioma) springing from the inner nuclear layer of retina, its location beautifully shown in Fig. 12, where a portion of the retina has been pressed against the posterior surface of the lens, the magnified growth shown here appearing as a minute nodule. (After Wintersteiner.)

spread, and near it could be detected a small fresh area of a similar nature.

There could now be no doubt about the diagnosis. The mother was informed that the eye was affected and was requested to return March 21 and bring the father, which she did. The areas of infiltration had increased both in area and thickness, and the parents were informed of the true

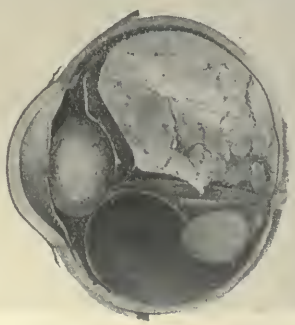

Fig. 12.—Section of globe, showing three gliomatous nodules in the totally detached retina, the third being very minute and seen near the posterior pole of the lens on which a part of the retina has been reflected. This nodule shown much magnified in Fig. 11. (After Wintersteiner.)

state of affairs. To save life enucleation was urged; that was refused, and the patient disappeared. Dr. S. C. Ayres was consulted and confirmed my diagnosis.

The child received no further professional attention till April 17, 1901, when the parents returned, asking that an operation be made, if only to relieve the sufferings of the child, as it now cried or moaned constantly, refused to eat, and was rapidly becoming emaciated. The globe was protruding and had ruptured (Fig. 13). The child was readmitted to the hospital the same day and under chloroform, exenteration of the orbit was performed solely to afford temporary relief from pain. The growth filled the orbit, the optic nerve having become enlarged so that its diameter was almost equal to that of the globe (Figs. 14 and 15). Caustics were not applied on account of the hopelessness of the case.

In three days the child had again become playful and free from pain. June 3 the cavity had healed. The child has gained in flesh and is very bright and happy.

In a recent communication the family physician, Dr. Sheppard, states that in September the patient began to suffer again and was seized with convulsions, which gradually increased in frequency and severity and could be controlled only by the administration of chloroform. The pain was never a "marked feature." The child died Nov. 7, 1901. No autopsy could be obtained..

CASE 3.—H. M., aged 2 years, was brought to me by her parents for a final opinion. I found it to be a typical case of

Fig. 13.—Baby Edwards.—Right eye removed three years before this picture was taken. No recurrence, nor was there any sign of it at the time of death, about eight months later. The left eye protruding and globe ruptured from extension of growth, beginning primarily in this eye.

neuro-epithelioma retinæ of the left eye at the end of the first stage, and advised immediate enucleation. They then informed me that this coincided with the opinion given by Drs. Ayres and Sattler. The operation was performed by them, and with their permission I merely state the condition of the patient as I saw her, and also her present condition as ascertained by a letter from the father, under date of Feb. 6, 1901, wherein he states that the child is in excellent health and attending school. A recent examination by an oculist showed the right eye to be perfect, excepting that it required a glass for correcting a moderate error of refraction, the vision becoming normal.

It is now 9 years since the operation, and as failure to recur after two years means a cure for the operated side, and the present age of the child (11 years) brings it almost absolutely beyond the period of development, we may consider the child's life saved.

CASE 4.—L. L., aged 18 months, was examined Jan. 18, 1897. His parents and grand-parents are all living and well;

no history of cancer, tuberculosis or consanguinity. He had chicken-pox at the age of six months, but no other diseases. About a month previous, the mother first noticed a glistening appearance of the left eye, at first toward the inner part, but it spread quickly, involving almost the whole of the pupil. On bandaging up the well eye, the child acted as if blind, and tried to remove the bandage. He sleeps well, has not lost

Fig. 14.—Baby Edwards. Left eye, showing also enormous infiltration of optic nerve.

any in weight, and apparently suffers no pain. The mother has three children older and in perfect health and has had one still-born.

This case was referred to me by Dr. F. G. Stueber, Lima, Ohio, for an opinion as to the character of the growth. As this was a typical case of glioma retinæ, in the latter part of

Fig. 15.—Baby Edwards. Section of left eye and portion of enormously infiltrated optic nerve. The lens was still clear.

the first stage, I could only confirm the Doctor's diagnosis, and urge, as he had done, the speedy removal of the eye, which was done Jan. 27, 1897, the examination after removal confirming the diagnosis. In answer to my letter of inquiry, sent Feb. 6, 1901, Dr. Stueber stated that the patient resided in an adjoining city. He last saw him June 25, 1897, when there was no evidence of return, and that he has since heard that he is still in perfect health.

In answer to a letter of inquiry, the mother answered, under date of Feb. 19, 1901, that the boy was in perfect health, with no evidence of a return of the growth, 4 years after the operation.

CASE 5.—H. W., aged 2 years. The following notes of this case I have taken from the record of my former associate, Dr. Joseph Aub: "About two weeks ago a yellowish-white reflex was first noticed in the right eye, which has been growing more perceptible daily, with deviation of the eye outwards. June 9, 1887.—The eye was examined to-day under chloroform. The entire inner and lower portion of the anterior half of the eye is taken up by a tumor, irregular in shape, and rich in blood vessels upon its surface. The entire outer half of the retina is detached; tension normal; deviation outwards well marked; no response to light. Dr. S. C. Ayres having been consulted, and agreeing in the diagnosis, assisted in the enucleation of the eye. Removed a liberal piece of optic nerve. Prompt healing."

I examined this patient in November, 1901, more than 14 years after the operation, and found the orbital cavity normal, both in size and appearance, and absolutely no asymmetry of the face, a point of interest in connection with the removal of the globe during infancy. The left eye was normal.

RESUME OF THE CASES.

Counting each eye as a case we have six operations. In speaking of a cure, I refer only to the operated eye.

Case 1.—Right. Third stage. Optic nerve affected beyond point of section. Recurrence and death.

Case 2.—Right. Beginning of second stage. Optic nerve normal beyond point of section. Three years and two months since operation. Cured.

Case 3.—Left. Beginning of third stage. Optic nerve affected beyond point of section. Recurrence and death.

Case 4.—Left. End of first stage. Nine years since operation. Cured.

Case 5.—Left. End of first stage. Four years since operation. Cured.

Case 6.—Right. End of first stage. Fourteen years since operation. Cured.

Three cases, or 50 per cent., were operated on during the first stage and all were cured; one case operated on in the second stage was cured. Two cases operated on in the third stage were fatal.

While the number of cases is very small, yet there can be no doubt that operations during the first stage with extensive resection of the optic nerve will give us a large percentage of recoveries for the operated side. We must also remember that in a great many of these cases the affection will involve the other eye sooner or later; by early removal of the second eye, however, the patient's life may be saved.

DISCUSSION.

DR. HERMAN KNAPP, New York—I had a case in which the eye was removed while still seeing. When I first saw the case the diagnosis was somewhat doubtful, but in three or four months I saw the case again, when the picture of glioma was very distinct and I advised enucleation. The mother consented, the operation was done without accident, and everything went on nicely, but the parents sued me for damages and gave me a great deal of trouble. I had to furnish proof that it was a glioma. I had the specimen and experts testified that it was cancer and that without operation death would have inevitably resulted. Then I had to prove that that specimen was the eye of the patient. Some of my colleagues had seen the patient before the operation and testified that it was his eye. Then I had to prove that this was the boy the witnesses had seen. Then they made the plea that the eye had been removed without knowledge of the parents, although it had been done with their consent, and some of the students who had been present at the examination testified to that fact. The question was raised of what

would have been the result if the boy had been let alone, and the experts all testified, inevitable death. Dr. Henry D. Noyes, as an expert, said that it was the unanimous verdict of the profession that no one with that disease can live without an operation and without an early operation. The judge asked Dr. Noyes: "Are you a friend of Dr. Knapp?" Dr. Noyes said: "We have been competitors in the same field of work, but we have always been on friendly terms." Then the judge said: "The case is clear; the Doctor did his duty: he sacrificed the limb to save life. The jury is dismissed."

DR. JOHN E. WEEKS, New York—I want to speak of one point: the involvement of mesoblastic tissue as these tumors advance. It is not unusual to find mingled with the cells that make up the glioma, cells that are distinctly of mesoblastic origin, so that the term glio-sarcoma is particularly applicable in these cases. Epitheliomata when they recur sometimes present the appearance of epitheliomatous tissue combined with sarcomatous tissue.

DR. S. C. AYRES, Cincinnati—In reference to one of the Doctor's cases, I am familiar with it and it is nine years now since the enucleation and she is in very good health.

DR. A. R. BAKER, Cleveland—Just a word in regard to the difficulties of diagnosis. I enucleated an eye two or three weeks ago in which I had diagnosed glioma and in which several local oculists made the same diagnosis and yet the pathologist says he does not think it is glioma. A few years since we had another case in Cleveland in which we made a diagnosis of glioma and enucleated the eye and when the pathologist opened it up it was a mere cyst with a very thin wall. The only other case in which I have diagnosed glioma was one I met in my first year of practice, in which I enucleated and the child died subsequently from recurrence.

DR. EDWARD JACKSON, Denver—Within a year I have seen and studied, ophthalmoscopically, an eye, regarding which, had it been in a child, I would certainly have made a diagnosis of glioma. It is a blind eye, in a woman nearly forty. It has been blind for many years. I think it is probably of the nature of a case reported by Dr. de Schweinitz last year at the American Ophthalmological Society, in which he enucleated the eye. There was a greatly thickened, degenerated, partially cystic retina. In my case there was a clear vitreous, and the retina markedly thickened and of irregular surface. Without the history of blindness for many years, and the patient being an adult, I think one would be justified in making a diagnosis of glioma.

DR. LUCIEN HOWE, Buffalo, N. Y.—I just want to say that I think we report our cases of pseudo-glioma more promptly now. On looking up the literature I find that there are very many more cases on record than I had any idea of. If such cases were reported oftener we would have less trouble about malpractice suits. When there is reasonable doubt, I am inclined to think the eye should be removed.

DR. WALTER L. PYLE, Philadelphia—I desire to cite a very unusual source of confusion in the diagnosis of retinal glioma, which has not been mentioned. Recently, we had at Wills' Hospital a case which, according to general consensus, was one of advanced retinal glioma, but which after enucleation proved to be subretinal cysticercus.

DR. S. D. RISLEY, Philadelphia—The differential diagnosis between true glioma and pseudo-glioma is in some cases very difficult. I recall one instance where, after consultation with several colleagues of the staff at the Wills' Hospital the consensus of opinion was in favor of pseudo-glioma. Operation was deferred and the child discharged from the hospital, but returned in two weeks with great pain and marked increase of tension. The ball was excised and the growth proved to be a true glioma. It would have been better to have erred on the side of safety and enucleated the eye at once. The disease speedily progressed in the orbit and the child died in a few weeks.

DR. MARK D. STEVENSON, Akron, Ohio—A few years ago I had a case in which a diagnosis of glioma retinæ was made. It was then very small and I advised enucleation; the parents refused an operation after other specialists had claimed it was not glioma. The eye was removed about a year later in another city, and the child has since died from an extension of the tumor to the brain. A blind eye presenting a typical glioma should be immediately removed, as there is little to gain and much to lose by delay.

DR. HOLMES, in closing—In two out of three in the first stage the tumor was quite small, one not filling up more than one-quarter of the globe, so that there was considerable sight left at the time of enucleation. In the double enucleation there was no recurrence in the other eye for two months after the first was removed. The mother brought the child in because she thought its sight was failing, as it was beginning to stumble, and on examination we found the very beginning of a glioma, so small that others who saw it thought it might be acute exudative choroiditis. They came back in one week when it had grown considerably and two weeks later enucleation was advised, but refused. They came back five or six months afterward to have the eye removed for relief of pain.

I think it is very important to secure witnesses and the absolute consent, preferably in writing, from the parents, if you are going to remove an eye that still has considerable sight left. I think the golden rule applies in these cases—when in doubt, take the side of safety. In one case called pseudo-glioma I had to remove the eye afterward on account of inflammatory condition and I deem it best to take the side of safety and remove an eye that you can not prove to be pseudo-glioma.

GASTROINTESTINAL PERFORATIONS AND THEIR DIAGNOSIS.*

F. GREGORY CONNELL, M.D.
SURGEON TO ST. VINCENT'S HOSPITAL.
LEADVILLE, COLO.

INTRODUCTION.

That the most urgent need of the surgeon, when called to a gunshot wound of the abdomen, at the end of the nineteenth century, should be exactly similar to that of the surgeon under the same circumstances during the closing days of the eighteenth century is truly a remarkable circumstance. This painful lack of ingenuity or resourcefulness is a sad commentary on the century, which in many respects has been so brilliant from a surgical point of view.

In support of the accuracy of the above statement, a glance at what might be called ancient history will reveal an instance in which exactly similar circumstances gave rise to exactly the same line of thought with the employment of almost the same methods and materials in an effort to arrive at an early diagnosis in a case of suspected or possible perforation of the gut. In "Hunter on the Blood and Inflammation and Gunshot Wounds"[1] we find the report of a gunshot wound of the abdomen. At that time, as in our own day, the all-important question was as to the perforation or nonperforation of the "tractus alimentarius." In this connection he tells us that "fumes of tobacco by clyster" were prepared, "but fearing that such a procedure would cause an increase of the disease" they were loathe to employ it, and finally decided not to do so, the patient dying in about thirty-six hours.

Here is a suspected perforation occurring over one hundred years ago, and it is worthy of note that practically parallel cases (if the words hydrogen gas or ether vapor be substituted for fumes of tobacco, and with the exception that fear of an increase of the disease did not prevent the later surgeons from carrying the idea into effect) may be found in the literature not far from the close of the last century. This striking similarity shows

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. H. O. Walker, A. J. Ochsner and DeForest Willard.

but a pitiful progress, and it is our earnest desire and sincere hope that the next few decades may present a better showing in this particularly and singularly neglected phase of abdominal surgery.

The sciences of medicine and surgery differ radically in many respects, but in none is the difference so striking as in the character of the advances made in these respective branches during the past few years. In medicine progress has been made in enormous and rapid strides, almost exclusively along the line of diagnosis, resulting in an almost absolute and early diagnosis in many of the more common diseases, such as typhoid, pneumonia or tuberculosis. But, comparatively speaking, medical treatment is far behind the methods of medical diagnosis, and in many instances, despite new modifications and suggestions, the treatment is substantially the same as that practiced years ago.

Osler[2] says, speaking of pneumonia, under diagnosis: "No disease is more readily recognized, in a large majority of cases"; and under treatment says: "Pneumonia is a self-limited disease and runs its course uninfluenced in any way by medicine, and can neither be aborted or cut short by any known means at our command."

William Pepper,[3] speaking of typhoid fever, says: "In this disease it is preëminently true that a good nurse without any doctor is better than the best doctor without a good nurse."

Osler[2] says: "The profession was long in learning that typhoid fever is not a disease to be treated by medicines; careful nursing and a regulated diet are the essentials in a majority of the cases." And speaking of the treatment of tuberculosis: "No medical agents have any special or peculiar action on the tuberculous process." On the other hand, we find wonderful advancement in the diagnosis of these same conditions which defy any specific treatment. Such measures as the diazo and the Widal reaction, while not absolute, are of great aid in doubtful cases of typhoid. The finding of the tubercle bacilli and the tuberculin test aid materially in making the diagnosis of tuberculosis a very simple matter.

Refinements of diagnostic measures, while of the greatest value in many cases and good things in themselves, are of little or no avail unless there is some method of efficient treatment which can be instituted as soon as this early and accurate diagnosis has been arrived at.

In the domain of surgery the most striking improvements have been in the line of treatment, and, exactly opposite to the subject of medicine, diagnosis has not kept apace. For example, carcinoma and other malignant neoplasms and peritonitis can be treated successfully if recognized early, but are rarely diagnosed before treatment is of little avail. This is a most deplorable condition of affairs and should be improved. Of what value is it to physician, patient or relatives to be able to diagnosticate correctly and soon after onset a case of pneumonia, if no remedy or line of treatment is at hand with which to cure the disease? On the other hand, of what value is it to be able to remove a carcinoma of the pylorus, or even to ablate successfully the entire stomach, if we are unable to make a diagnosis till very evident symptoms arise, by which time the size of the tumor or metastasis will have made the removal of the entire growth and ultimate recovery of the patient an absolute impossibility; or again, in perforation of the intestine, if repaired immediately after injury, the result almost invariably will be union of the gut and recovery of the patient. But of what value is this familiarity with the technic of the enterorrhaphy when one does not know whether or not there is present an injury of the gut?

In the coming century the indications to be fulfilled are: in medicine, advancement in treatment, so that the physician will not only know the pathologic condition present, but in addition will be able to initiate some line of treatment which will result in the recovery of the patient. In surgery, on the other hand, treatment has advanced as far as it is practicable, and shall have to progress more slowly while the attention of originators and investigators is devoted to improvements of diagnosis, so that the surgeon will not only be familar with the *modus operandi* of the various operative procedures, but will also be enabled to employ them at a time when he can, at least, hope for more than palliation as a result.

The past century, so productive of exceedingly valuable suggestions and discoveries in all branches of medicine and surgery, has passed by the diagnosis of the gastrointestinal perforation almost without a trace of improvement. To be sure, attempts at an early diagnosis have been made, but the methods employed have been so crude and unscientific that the wonder is, not that they have been relegated to the past, but that they had ever been proposed seriously, even by their originators.

OLDER METHODS OF DIAGNOSIS.

The different attempts in this line may be arranged in a chronologic way, as follows:

1. Hunter: Fumes of tobacco by clyster.
2. Senn: Hydrogen gas per rectum.
3. Sutton: Ether vapor per rectum.
4. Finney: Abdominal incision.
5. Lofton: Intestinal perforation searcher.
6. Exploratory needle and syringe.

The earliest suggestions along this line we find in "Hunter on the Blood and Inflammation and Gunshot Wounds," already referred to, where no other attempt is seen in the available literature till in 1888, when Senn[4] advocated the injection of hydrogen gas per rectum as an "infallible" method of determining whether or not the gastrointestinal tract was intact. If so, the gas made a harmless passage and escaped at mouth. If a perforation existed, then after causing tympanites the gas was found to escape at the abdominal wound, where it was recognized by its being ignited and burning with a characteristic blue flame.

And again in 1898, Senn[5] claimed: "The writer has shown by his experiments on animals, and later by his clinical experiments in the treatment of a number of cases of gunshot wounds of the abdomen, that the rectal insufflations of hydrogen gas can be relied on in demonstrating the existence of perforations of the gastrointestinal canal before opening the abdomen." But despite this claim, the fear of causing fecal extravasation and the unreliability of the method has prevented its adoption.

Floyd McRae[6] says: "As to the gas test of Senn, it is worse than useless; it is dangerous; it is only corroborative; it is not conclusive as to a nonperforation and it greatly enhances the difficulty of the subsequent operation and increases the danger to the patient, because it produces extravasation of the contents of the alimentary canal into the peritoneal cavity."

Thomas Manley[7] says: "Inflation of the alimentary canal, from either above or below, may perhaps aid in deciding upon the diagnosis, but it must be regarded as

an expedient attended with more danger than counterbalances the additional knowledge it may convey."

In 1898 E. M. Sutton[8] reports some experiments in which he injected air, impregnated with ether, into the rectum as an aid in diagnosing gastrointestinal perforations, claiming as advantages over hydrogen gas that the ingredients are always at hand and no special apparatus is necessary and there are no noxious properties. He[9] reports a case of gunshot wound of the abdomen in which the alimentary tract was possibly injured; vapor of ether injected into the rectum was soon belched from the stomach. On which the diagnosis of no perforation was made, which in all probability was correct, because the patient made an uneventful recovery. The objections preventing the adoption of the hydrogen gas method applies with equal force to both of the other methods similar in character, tobacco fumes and ether vapor.

In Keen's[10] article on "Surgical Treatment of Perforation of the Bowel in Typhoid Fever," we find he gives Finney credit for the suggestion "that in any case in which the diagnosis is obscure and there is reason to suspect the existence of a perforation, a small incision be made under cocain anesthesia and that cultures be taken from the abdominal cavity. This exploratory incision would be followed by very little disturbance to the patient and very slight risk. If the presence of a septic peritonitis is determined this incision can be enlarged and the operation for the relief of the perforation and peritonitis can be at once carried out."

The most obvious objection to any such method is that we must await the development of a peritonitis. A diagnosis so early that when reached, the treatment will concern the perforation alone and at a time when there will be present no peritonitis to complicate the prognosis and treatment, is the need, a fulfillment of which we are endeavoring to find.

If we are to rely on this method in cases in which "the diagnosis is obscure," which will be in the great majority of perforations, we must await the increase in growth of the bacteria after their escape from the lumen of the canal in order to find them after making a small abdominal incision; in fact, we must await the development of a peritonitis before we are sure of the diagnosis. Its negative value would certainly be questionable, for cases will occur in which the incision and cultures were made too soon, before the bacteria have had time to multiply, which, if examined later, would give a positive result. Such a method when positive would frequently be too late and when negative could not be relied on universally. A case warranting an opening of the abdomen for possible perforation would certainly warrant, in addition, an exploration of the intestinal tube; to stop short of that after having opened the abdominal cavity, either by a large or a small incision, is insufficient.

The use of the exploring needle as a diagnostic measure in cases of peritonitis, perforative or otherwise, has been recommended. Osler[2] relates a case of ruptured tubal pregnancy which closely simulated peritonitis, in which he withdrew a bloody fluid from the peritoneal cavity with an aspirating syringe. But the question is ably summed up by R. H. Fitz:[11] "With reference to the exploring needle, the needle thrust into the iliac region may draw out a fluid which looks like pus and smells like pus, but which in reality is intestinal contents, so that apparently positive results are not necessarily demonstrative of pus. On the other hand, negative results are so numerous that it is better to place no dependence on the use of the exploring needle."

In 1901 Lucien Lofton[12] described an intestinal perforation searcher, which consists of a smooth glass tube 24 inches long and half an inch in circumference with an enlarged funnel-shaped extremity at one end. After perfect sterilization a small, loosely-fitting piece of dry absorbent cotton is inserted into the enlarged end, and the smaller end now allowed to descend into the abdominal cavity. When by continued application of your nose to the funnel, should perforation exist, you will almost immediately get the aroma of escaping intestinal fluids.

Chemistry, electricity, the *x*-ray, the microscope, spectroscope and the polariscope have performed feats of diagnosis but little short of the miraculous in many branches of medicine and surgery, but in the case of the gastrointestinal perforations these exceedingly important adjuncts to diagnosis have not been called on to contribute to our information. As Chittenden[13] has said: "The time is at hand when the practice of medicine is becoming what it was long ago, but then unjustly called a true science and art. No continuing success can be built on the empiricism or on the proportion of guess-work which is inseparable from the dependence on the experienced eye. Diagnosis is now the pass word in medical science."

PRESENT ACCEPTED METHODS: A. TO WAIT FOR SYMPTOMS.

In the usual cases of penetrating wounds, in all cases of contused wounds of the abdomen, in many cases of typhoid and other ulcerations of the gastrointestinal tract, it is absolutely impossible to arrive at a diagnosis of perforation before: 1, the development of the characteristic signs and symptoms of peritonitis, or 2, unless an exploratory laparotomy is performed. In the unusual cases, such as those which the injured viscus presents at the abdominal wound or in which the contents escape, the diagnosis is, of course, self-evident, but unfortunately such cases are extremely rare, and as regards them sufficient will have been said in their mention.

Maurice Richardson:[14] "The truth is that no exact diagnosis is possible in the early hours of many acute abdominal emergencies."

E. D. Fenner:[15] "I am impressed by the fact that we can never tell from general symptoms, or external appearances, whether the viscera have been wounded or not."

Flagg:[16] "When a man receives a penetrating gunshot wound of the abdomen there is no immediate way of determining without operation if the abdominal viscera are wounded or hemorrhage is taking place."

N. Senn:[17] "A visceral injury of the stomach or intestine seldom gives rise to symptoms on which the surgeon could rely in making a positive diagnosis."

The chief objection to awaiting the development of a peritonitis in a case of suspected perforation (which will be characterized by pain, collapse, vomiting, abdominal tenderness and rigidity, resp. costal, rapid and superficial 30 to 40, temperature 100 to 103 F., or subnormal, pulse rapid, small and weak, 100 to 150 tongue dry and coated, free fluid in abdominal cavity, liver dulness absent, tympanites—and with all these the well-known facies, Hippocratic) is that, if such be the correct suspicion, the diagnosis will not be arrived at till the peritonitis will have become so far advanced that in the majority of cases with our present methods the treatment will be of little or no value. Instead of being called on to repair a simple intestinal perforation, we must treat a case of peritonitis, more or less virulent, complicated with a perforation of the intestinal tube.

Fitz[3] says: "Peritonitis from perforation of the stomach or free portion of the intestine into the normal peritoneal cavity is almost invariably fatal." If this be true it is therefore our plain duty to diagnose and repair the damaged gut before peritonitis has become established, if possible; if not possible, then before it has progressed very far. That leads us to the question: How soon after perforation does peritonitis set in? This, unfortunately, can not be answered directly, because it is dependent on many qualifying circumstances, such as the number and the caliber of the perforation, the locality of the same, the variety, character or virulency of the escaping intestinal contents and, of no little importance, the resistance of the individual against infection. Peritonitis following intestinal perforations is dependent for its characteristics on the bacterial flora of the canal at the site of traumatism.

Cushing[18] has shown that in the upper portion of the intestinal tract the bacterial flora is more scanty than in the lower portion, hence wounds of the duodenum and jejunum are less fatal than wounds of the lower portion of the ileum and large bowel, all other conditions being equal.

In Keen and Tinker's[10] table of 158 cases of typhoid perforations, the shortest space of time elapsing between perforation and operation was one and one-half hours, in which case there was "a marked general peritonitis" present at the time of the operation, and in another case, four hours after perforation, "seropurulent fluid in peritoneal cavity, serosa injected," is noted. In another, after same time, "Considerable cloudy serous fluid was noted in abdominal cavity with some serous flakes on intestine." In none of the 158 cases, the time varying one and one-half hours to several days, is the absence of peritonitis noted.

Briggs,[19] in reviewing six cases of typhoid perforation operated on 8, 5, 4, 3, 1, and an unknown number of hours after perforation, says: "There was a moderate degree of peritonitis at the time of operation in all these cases judging from the amount of free fluid in the abdominal cavity."

In Shattuck, Warren and Cobb's[20] series of 24 cases, at the operation general septic peritonitis was not evident to the eye in Cases 1, 3 or 7. 1. Operated on in 3 hours; death 5 days; internal hemorrhage. 3. Operated on in 2 hours; death in 3 days; general peritonitis. 7. Operated on in 8 hours after pain, 5 hours after collapse; no free fluid; no extensive sign of peritonitis.

Robinson[21] says, in speaking of gunshot wounds of abdomen in military practice: "Generally it is from six to twelve hours or more before these cases can be brought to the operating table, and at that time infection, if it is to occur, has already taken place, or if not the danger is passed."

In Oliver's[22] tables of gunshot wounds of abdomen we find a case operated on one and one-half hours after the accident, and at operation a wound of the stomach with "a beginning general peritonitis" was noted.

Richardson[14] says, in speaking of gastric ulcer perforations: "By the end of twelve hours, and often sooner, the infection of the first few moments has become a peritonitis under full headway."

In Tinker's[14] analysis of 75 cases of perforated gastric ulcers which were operated on, the shortest time elapsing between perforation and operation was two and three-fourths hours, and at operation "a turbid fluid with lymph flakes on omentum and liver" was found.

H. Gage[23] details four cases of traumatic rupture of intestine, the shortest time between accident and operation was twenty-six hours, and at that time peritonitis was fully established.

Cushing[24] says: "In Case 1: An early diagnosis and immediate operation *before peritonitis set in* (italics are ours) led to recovery." In describing the operation, he says: "On opening the peritoneal cavity a considerable amount (perhaps 200 c.c.) of the seropurulent fluid escaped, coming chiefly from the pelvis. Cultures were taken from the fluid and it was immediately examined in cover-slip preparations. It contained a great number of polymorphonuclear leucocytes, but no microörganisms could be found. The serosa of the intestine was everywhere greatly congested, but evidently the greatest reaction was in the right iliac fossa, where the ileum was especially injected and covered with a slight fibrinous deposit. . . . . A few fine, filmy adhesions held the omentum to this part of the bowel," and on page 215 he again repeats: "The picture was complete *before* the onset of peritonitis," and on page 216: "The perforation was closed *before* there was *any evidence* of peritoneal infection, the culture from the free fluid remaining sterile."

In this case there certainly was a peritonitis present at the time of the operation, which accounts for the "seropurulent fluid containing many polymorphonuclear leucocytes (pus), the injection of the serosa of the intestine, especially in the right iliac fossa, with the slight fibrinous deposit and the few fine, filmy adhesions holding the omentum at this part of the bowel," and which gives a picture of beginning peritonitis. The fact that bacteria were not found and cultures from the free fluid remained sterile, does in no way prevent this condition from being properly called an inflammation of the peritoneum—a peritonitis. Had the case not been operated on, in all probability an abscess would have formed, which might have remained circumscribed for a greater or less length of time, and finally ruptured into the free peritoneal cavity, into the bowel, or externally, or not ruptured but lost its virulence and remained as an abscess. The formation of a fecal fistula is a most convincing argument that such was the case.

From these cases it will be seen that there is no exact space of time between perforation and peritonitis; it is long in some and short in others; therefore, as we do not know which will be short and which will be long, we must act as though the time will be short in all. A second reason for not awaiting the appearance of peritonitis in such suspected cases is, that very frequently the complete symptom complex may not appear, one or more of the more important features may be absent, with a peritonitis progressing rapidly.

F. A. Dunham[2] has said: "The more virulent the infection the less marked are the local signs of peritonitis," so casting a shadow of doubt on the diagnosis, even after waiting, and as a result of the waiting nothing at all has been gained. For example, Alex McPhedran[25] cites a case of apyrexial typhoid, a man in fair physical condition, in which perforation occurred without any localizing adhesions and symptoms of only moderate severity, not sufficient to alarm either himself or his friends."

C. A. B. Horsford reported an interesting case of perforated gastric ulcer in which the gastric contents escaped and accumulated in the right iliac fossa, presenting all the symptoms of appendicitis. The patient did not have the physical symptoms accompanying perforation; the pain was not severe, the abdomen was not generally distended, and the symptoms giving rise to a diagnosis of appendicitis did not arise until several days

after the perforation took place. The patient was not operated on, but the condition was discovered postmortem. Again in typhoid, especially where the patient is in the typhoid state and unconscious, the symptoms of pain and tenderness may not be attainable, thus casting a legitimate doubt on the diagnosis.

Cushing[24] has described "a preperforated stage of typhoid ulceration," during which, usually occupying several days, we may notice abdominal pain, tenderness and leucocytosis, with a disappearance of the latter after perforation has actually occurred. This pain he attributes to involvement of the serosa, with possibly the formation of omental adhesions. He includes in this stage the whole period between the first involvement of the serosa with the formation of customary adhesions until these adhesions (which may for a time form the floor of the ulcer after the serosa has given away) have themselves broken down and general peritonitis has taken place.

But Monad and Van Verts,[26] after examining the histories of 27 cases, say that the formation of these adhesions in threatened perforation is exceedingly rare. They also claim that peritoneal infection is not always a rapid fulminating affair; that it may occur by the migration of the bacteria through the damaged and almost necrosed intestinal wall.

Cobb[20] says: "In mild cases of typhoid complaints of abdominal pain should lead to a strong suspicion of beginning peritoneal infection through a preperforative stage, or a slow peritoneal infection through a perforation with or without temporary adhesion, or a beginning infection from some other source than the intestine."

A. Berg,[27] in discussing the preperforative stage, says: "Even granting that the peritoneal symptoms are from an involvement of the serosa, which covers a deep ulceration of the Peyer's patch, does this mean necessarily that the serosa will always give way and permit of extravasation into the free peritoneal cavity? Certainly not. How, then, can we think of interfering surgically for a perforation that does not exist and which may never take place? When our diagnostic acumen will have reached a higher stage of development, so that we can differentiate the signs of local peritonitis as caused by an impending perforation from the peritonitis produced by other pathological conditions, and when we are able to foretell which serosa over a deep ulceration will give way, then the preperforative stage will be a reality."

Keen,[10] in speaking of this preperforative stage, says: "Should it ever prove possible to accurately diagnose the preperforative stage, that unquestionably will be the most favorable time for the operation." And in his conclusion: "If it be possible to determine the existence of a preperforative stage."

Another reason why it is an unsafe practice to await the symptoms of peritonitis in these cases is that such symptoms are in some instances absolutely unreliable; they may be present more or less completely and at operation no perforation, or even peritonitis, may be found.

Shattuck, Warren and Cobb, in their series of 24 cases of operations for perforation, report three cases in which the symptoms lead to operation, but no perforation nor peritonitis was found at the operation. Two of these cases recovered and one died.

Cushing, in eight cases, reports three operated on for perforation, in which no perforation existed; in one no lesion to account for the symptom was found at the operation; recovery was uneventful. In another the symptoms were caused by an iliac thrombosis; the patient subsequently died of pulmonary embolism; and in the third the symptoms of perforation were due to appendicular colic. No perforation was found, but a chronic adherent appendix was removed; recovery.

Briggs, in a series of six cases, reports one in which symptoms of perforation occurred, but the opening of the abdomen under local anesthesia revealed a peritoneal cavity apparently normal and no perforation to be found; convalescence slow; recovery.

G. G. Davis[28] reports three cases of typhoid operated on for perforation; there was no perforation found in one case; recovery.

At the last meeting of the Association of American Physicians, A. H. Smith presented a paper entitled "Two Cases of Supposed Gastric Perforation," in which no explanation of symptoms was found at operation.

So if mistakes are made by these experienced clinicians (1 in 6, 3 in 8, 3 in 24), surely if the less talented men are to follow in their footsteps more mistakes will result. To be sure, in these cases few deaths and little or no inconvenience have resulted, but in those less favored by surroundings and nature, who are to make their diagnosis on these symptoms, will they meet with as fortunate an outcome? Perhaps if all cases were reported we might discover that death will occur oftener than we find in these reports.

Among the many conditions which may resemble peritonitis so closely as to lead to the error, we call attention to acute entero-colitis, intestinal obstruction, acute hemorrhagic pancreatitis, hysterical peritonitis, embolism of mesenteric artery, ruptured tubal pregnancy, intestinal hemorrhage, cholecystitis, suppurative mesenteric glands, diaphragmatic pleurisy, iliac thrombosis, appendicular attacks, etc.

There is no pathognomonic sign or symptom or group of symptoms of doubtful perforation of the gastrointestinal tract, Stewart to the contrary notwithsanding, who says:[29] "Obliteration of dulness in a flat belly or resonance over the posterior and lateral areas of hepatic dulness, in the distended abdomen and cellular emphysema are the only pathognomonic signs of ruptured intestine. They are not due to infection, but are the rare signs of rupture, not ulcerative, perforation of the gut." He then adds: "The occurrence of any of the above signs should make us suspicious, and suspicion should in most cases be synonymous with exploration." Showing that the above signs are not pathognomonic for they should merely make us suspicious, as pathognomonic signs are unmistakable indications of a given disorder, the term suspicious rather than pathognomonic should have been used.

Those cases in which the intestinal contents escape from the abdominal wound, or in which the injured portion of the gut presents at the wound, are not doubtful cases, but instead are plainly evident and have been spoken of above.

In the doubtful or possible perforation the absence of the liver dulness was for a time looked on as a positive indication of this condition, but its value as such has been questioned, since it has been demonstrated that the liver dulness may be diminished or even obliterated by tympanites alone.[15] This is accounted for by a distended coil of intestine insinuating itself between the liver and the abdominal wall, or in the case of extreme distention of the intestine the liver, entire, may be pushed up.

Another fact showing the fallibility of the sign is that in many cases in which the liver dulness was normal, at operation perforations have been found, so rendering it worthless as either a positive or negative sign.

An uncommon symptom is "The Acoustic Phenomenon of Levaschoff." A rushing sound was heard with

the stethoscope synchronous with the descent of the diaphragm, caused by the air or gas passing through the perforation, owing to the increased pressure due to the descent of the diaphragm. But it is rarely noted and is not now generally accepted.

The presence of free fluid in the abdominal cavity, in connection with the other symptoms, may point strongly toward a perforation, but it must be remembered that hemorrhage alone may give rise to the same physical signs, also simple hydroperitoneum must be excluded. On the other hand, in very few cases of perforation is there an escape of sufficient fluid to be detected at an early physical examination, at a later date, when the symptom is of infinitely less value, it may, of course, be found in some cases.

Kinnecutt[30] has been able to detect, early in these cases, before abdominal respirations have ceased, a fine peritoneal crepitation very similar to that heard over an inflamed pleura; a very careful auscultation of the entire abdomen is necessary, and it has as yet not been generally adopted.

Hematemesis after probable perforation of the stomach has been looked on, and is still regarded by many, as a pathognomonic sign of perforation of the stomach, but Rodman[31] quotes a case of Mayo Robson as follows: "I explored the abdomen for a stab wound, and as the patient was vomiting blood I expected to find a wound of the stomach, but discovered no perforation of the stomach wall, though I had to ligate the superior mesenteric vein, the patient making a satisfactory recovery; the hemorrhage was undoubtedly due to the bruising of the mucous membrane without rupture of the peritoneal coat." Thus showing that hematemesis after abdominal injury can not be relied on as a positive sign of perforation. In injury of the intestine the passage of blood per anum might, of course, be explained as above, but usually would occur too late to be of any practical value.

Leucocytosis as an aid to the immediate diagnosis of perforation has not been dwelt on to any great extent except in typhoid perforations.

Bloodgood[32] says: "Examinations of the blood after abdominal contusion, to ascertain the existence of shock, hemorrhage or peritonitis, are not sufficient in number to allow of any conclusions."

Leucocytosis in acute peritonitis has attracted more attention, but in this connection it is not of so much value as the former, for it is our aim to arrive at the diagnosis before the establishment of a peritonitis, and when it is once established we can, as a rule, make a diagnosis without the aid of the leucocyte count.

As regards perforation and leucocytosis during typhoid, to explain the present status of affairs and to show the conflicting opinions among authorities, we may quote from Cabot: "A steadily increasing leucocytosis is always a bad sign and should never be disregarded, even when other bad symptoms are absent"; and from Cushing, who adds: "That a decreasing leucocytosis may be a much worse sign and should never be disregarded." This he explains very rationally as follows: "If there develops a localized peritonitis associated possibly with a preperforative stage of ulceration, or with a circumscribed slow-forming peritonitis, after perforation, it will usually be accompanied by an increase of leucocytes in the peripheral circulation; but if a general septic peritonitis develop the leucocytosis may be but transitory or overlooked, as it will disappear concomitantly with the great outpouring of the leucocytes into the general cavity."

So it seems that an increase of leucocytes signifies some inflammatory complications, such as phlebitis, otitis media, pneumonia, etc., among which may be localized peritonitis.

On the other hand, a fall of the leucocytes conveys to us the information that a diffuse septic peritonitis has already become established, the one thing we do not want to wait for. This drop in the leucocytosis does not occur at the time of the perforation, as we are led to believe, but, if the theory as to its cause is correct, it occurs at the time of the development of the diffuse septic peritonitis.

The so-called wave of leucocytosis, the gradual increase and then a sudden decrease, is considered by Cushing to be particularly characteristic of perforation, but Cabot, Blake and Hubbard[33] made frequent blood counts in normal individuals and patients suffering from typhoid, in which no perforation occurred, and found such a wave as described above, and they conclude: "That leucocytosis usually exists in typhoid perforations, but in order to be of diagnostic value such leucocytosis must be relatively steady and not of the type described by Cushing."

Leucocytosis in most cases must be considered as an ordinary symptom, subject to the various uncertain changes of any such symptom. It may at times be conspiciously prominent and again, for no visible or consistent reason, be entirely absent.

Such variations as perforation and even diffuse peritonitis with no leucocytosis, and in other cases characteristic leucocytosis with other symptoms, leading to an operation, which when performed shows no perforation or peritonitis, place it in the large category of unreliable symptoms.

Concerning the leucocytosis in conditions other than typhoid, most of the study has been in relation to appendicitis. A leucocyte count ranging between 10,000 to 15,000 or 17,000 can not be relied on to reflect the nature of the local lesion, since this degree of increase may be found in various conditions. But counts of 20,000 or more almost invariably indicate the presence of pus, gangrene or general peritonitis, one or all. But, on the other hand, again showing its uncertainty, in some cases of general peritonitis there will be no leucocytosis, because of the individuals being too weak to react against the infection.

J. M. Baldy[34] has recently written an article with the title of "The Examination of the Blood in Relation to Surgery, of Scientific but Often of no Practical Value and May Misguide the Surgeons."

(To be continued.)

The American Medical Association has prospered to such an extent during recent years that it now worthily represents the medical profession of the United States. That this was not the position of the society from ten to fifteen years ago is generally recognized in this country. We in Canada rejoice with the physicians of the American Republic in the growing prosperity of their great national medical association. The present happy condition is due largely to the increased harmony existing among medical men in all parts of the Union, the great executive ability shown by its officers, and the excellence of the official journal of the Association. The next meeting of the Association will be held in New Orleans, May 5 to 8, under the presidency of Dr. Frank Billings of Illinois. Special addresses—called orations—will be delivered as follows: Medicine, Dr. J. M. Anders of Philadelphia; Surgery, Dr. A F. Jonas of Omaha; State Medicine, Dr. Wm. H. Welch of Baltimore. It is quite needless to tell our readers that Canadians who attend this meeting will receive the same sort of kindly and hearty welcome which has invariably been extended to our countrymen in the past.—*Canadian Practitioner and Review.*

THE RESPIRATORY QUOTIENT AS INFLUENCED BY TUBERCULOSIS.*

T. M. ADERHOLD, M.D., AND W. S. HALL, M.D.
Department of Physiology, Northwestern University Medical School.
CHICAGO.

INTRODUCTION.

In 1777 Lavoissier showed that oxygen was absorbed from air during respiration and that it united with carbon in the body, forming carbon dioxid. This discovery caused many observers to determine the amount of oxygen consumed by normal animals and the amount of carbon dioxid given off by them. They also studied the relation of one to the other. When we consider the volume of carbon dioxid exhaled divided by the volume of oxygen consumed, this relation is known as the respiratory quotient. Generally more oxygen is consumed than carbon dioxid given off.

The object of these experiments was to determine the influence of tuberculosis on the respiratory quotient. A number of secondary facts have been established or confirmed, incidentally.

METHODS.

Some of the early experimenters (Black, Priestly and LaPlace) analyzed the air of a chamber before and after an animal had been confined in it. The objection to this method is that the animal is not in normal

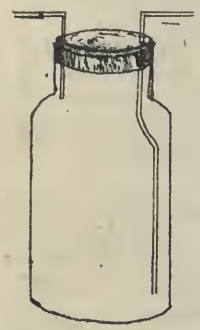

Fig. 1.—Animal cage. 1. A large mouth bottle large enough to hold a rabbit. 2. A piece of glass tubing 6 to 10 mm. in diameter which extends through the cork (air tight) to the bottom of the bottle. This is to secure perfect ventilation as the air which enters by (4) is liberated at the other end of the bottle. 3. The cork should be impregnated with paraffin and fit perfectly air tight. 4. Short piece of glass tubing 6 to 10 mm. in diameter which is connected to the tube extending to the outside of the room.

surroundings because: (1) The amount of oxygen is continually decreasing. (2) The amount of carbon dioxid is continually increasing. (3) The heat of the animal raises the temperature of the chamber. (4) The moisture in the chamber is continually increased by the animal. (5) The poisonous products exhaled by the animal may affect it.

Lavoissier first improved this method by absorbing the carbon dioxid as fast as it was formed and supplying fresh oxygen in its place and later by continually supplying fresh air to the cage and withdrawing the respired air. The majority of workers have followed this plan and have maintained a constant current of air by ventilating apparatus of some form.

Whatever general form of apparatus may be used, the carbon dioxid can be determined by (1) KOH or NaOH solution in an anthracometer (volumetric). (2) By KOH or NaOH solution in a Geissler bulb (gravimetric). (3) By passing the air over pumice stone saturated with the same solution. (4) By precipitation with $Ba(OH)_2$, and then by filtering, drying and weighing the precipitate, or by determining the amount of oxalic acid necessary to neutralize this solution.

The oxygen can be determined by: (1) Absorption with potassium pyrogallate and (a) by use of a large bulb (weighing before and after), (gravimetric), or (b) by taking samples of air in burettes and allowing the solution of potassium pyrogallate to run in from below (volumetric). (2) By exploding with electricity in an endiometer. (3) By oxidation of phosphorus in samples of air.

The moisture can be withdrawn from the air (1) by passing it through flasks or tubes containing concentrated H_2SO_4 or flasks containing pumice stone saturated with the same (weighing before and after). (2) By passing the air through these tubes containing desiccated $CaCl_2$ (weighing before and after).

The constant current of air through any form of apparatus is usually maintained by suction, either by use of water or mercury.

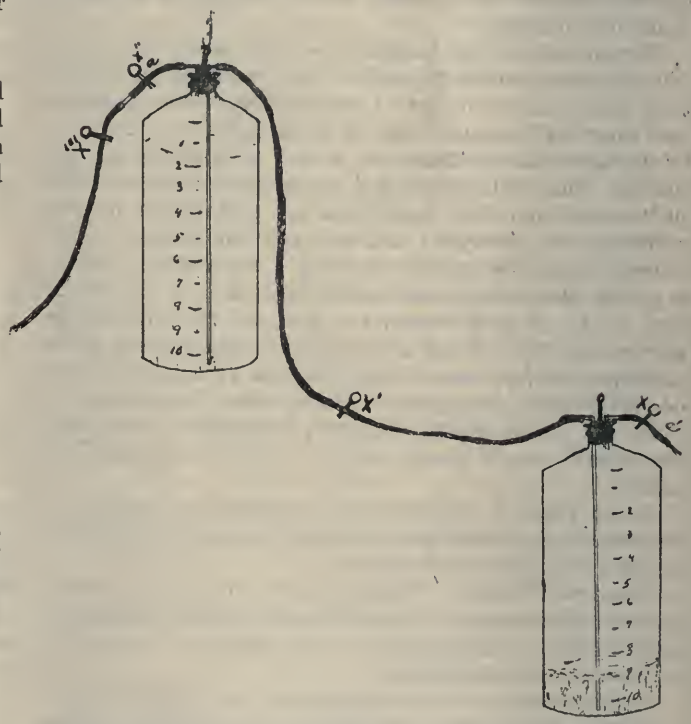

Fig. 2.—Showing the arrangement of the ventilating apparatus. The bottles equipped with air-tight corks and tubes as shown may be alternately raised and lowered by a strong cord running over a pulley attached to the ceiling. The siphon drawing off the water from the upper bottle lowers the pressure in it and draws a current of air through the apparatus. The amount of air supplied to the animal may be measured by noting the amount of water which traverses the siphon and may be varied by varying the height of the bottle. In alternating the position of the bottles one has only to lower the upper bottle and change the hook to the other bottle. The apparatus tube (*a*) should be changed to (*a'*) after clamping (*x'*) (*x''*) (*x'''*). In order to construct (*a*) (*a'*) so the clamps can be easily applied, it is necessary to connect a short piece of glass tubing to the glass tube which perforates the cork. This connection is made with a rubber tube on which the clamps are applied.

After performing a number of experiments we found the following method to be the most accurate and best suited for our work:

(*a*) For an animal cage we used a large mouthed glass jar, prepared for use as shown in Fig. 1.

(*b*) We maintained a constant stream of fresh air from outside of the room by a ventilating apparatus constructed as shown in Fig. 2.

(*c*) The water was collected by passing the air through tubes filled with desiccated $CaCl_2$ (weighing before and after). See Fig. 3.

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Pathology and Physiology, and approved for publicaton by the Executive Committee.

(*d*) The CO_2 was determined by passing the air current through a Geissler bulb containing a strong solution of KOH, to which is attached a small $CaCl_2$ tube for catching the moisture derived from KOH by the air current. This Geissler bulb and its attached $CaCl_2$ tube is placed in the apparatus beyond the large $CaCl_2$ tubes which absorb the moisture from the animal cage. It is weighed before and after the experiment. See Fig. 3.

In order to be certain that all of the CO_2 was absorbed by the KOH a flask containing $Ba(OH)_2$ was attached to the $CaCl_2$ tube of the Geissler bulb so that the $Ba(OH)_2$ would at once show a precipitate should any CO_2 not be absorbed in the Geissler bulb. See Fig. 3.

(*e*) The oxygen is determined by a volumetric method, using two or more gas burettes and a solution of potassium pyrogallate. See Fig. 4.

To determine the amount of oxygen which the animal consumes, samples of air are analyzed from each bottle of air which passed through the animal cage. The amount of oxygen in normal air is determined by analyzing samples of air from the bottles which ventilate the normal air apparatus.

In performing these analyses the greatest caution is necessary. The solution which gives the most accurate results is composed of two parts of 25 per cent. of KOH and one part of 5 per cent. pyrogallic acid. These two constituents should be mixed in the pressure tube (B) Fig. 4, just before the analysis is made. To collect samples of air for analysis one first fills the gas burette with water by suction. Connection is then made, by a

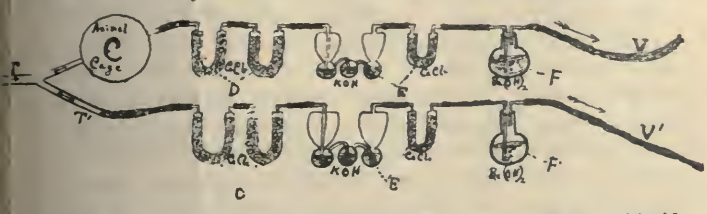

Fig. 3.—C. Animal cage explained in Fig. 1. D. Calcium chlorid tubes for collecting the moisture from animal cage. E. Geissler bulb, the bulbs of which are one-half full of 85 per cent. KOH, and to which is attached a small $CaCl_2$ tube for retaining the moisture derived from the KOH by the air current. F. Containing $Ba(OH)_2$ for detecting CO_2 which might not be absorbed in E. T. Tube which extends through the window to external air. T'. Tube which conducts part of the current to normal air apparatus. V. Connected with ventilating apparatus for animal cage. V'. Connected with ventilating apparatus for normal air.

rubber tube, with á from the top of the gas burette (A Fig. 4 to á Fig. 2). The stopcocks of the burette are turned so that the water in it escapes into the cup, as shown in Fig. 4, its place being taken by the respired air from the ventilating apparatus. The stopcocks are now turned so that no air can escape from the burette. The rubber tube of the pressure tube which has been filled with the potassium pyrogallate solution and previously freed from air is now connected to the lower end of the gas burette. See position 2, Fig. 4. If the three-way stopcock in the lower end of the gas burette (A) has been properly turned the solution from the pressure tube will escape from the end of the stopcock into the cup, as shown in position 2, Fig. 4. A small amount of the solution should be allowed to escape for the purpose of expelling bubbles of air which might have gained entrance to the lower end of the burette while connection was being made with the pressure tube. When all the air has escaped at the end of the three-way stopcock, it is turned one-half a revolution. If this has been properly done the solution will now run into the burette, coming in contact with the air to be analyzed. The pressure tube should now be elevated as high as the connecting rubber tube will admit and the potassium pyrogallate solution allowed to run into the burette (A). The clamp on the correcting tube should now be applied to it close to the lower end of the burette.

This operation made positive pressure in the burette, thereby causing a more rapid absorption of the oxygen. The burette should now be taken by the experimenter and its ends alternately raised and lowered. At frequent intervals he should loosen the clamp on the connecting rubber tube, and raise the pressure tube, thus permitting potassium pyrogallate solution to take the place of the oxygen as it is absorbed. This procedure should continue ten minutes, after which time the clamp on the connecting rubber tube should be loosened. The burette and its pressure tube should be allowed to remain ten minutes longer, at the end of which time the solution in the burette should be brought to a level with the solution in the pressure tube by elevating or lowering the tube. This causes the air in the burette to be under the atmospheric pressure existing at that time. The reading for the amount of oxygen is now taken.

To calculate the amount of oxygen consumed by the animal, one subtracts the amount of oxygen found in the

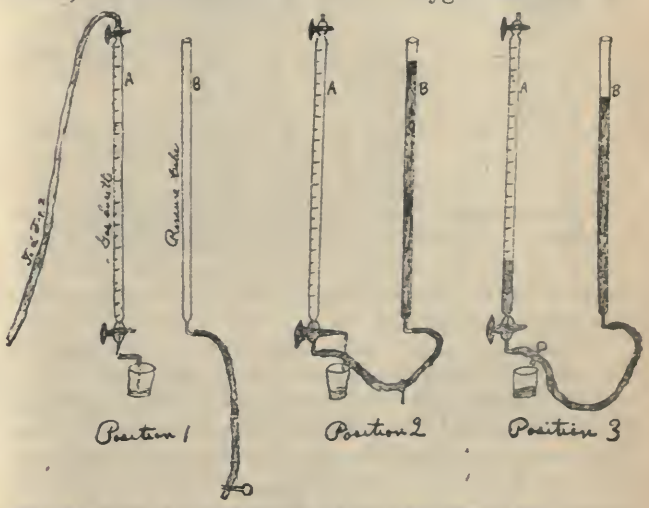

Fig. 4.—Position of gas burettes during analysis of air. Attach a tube from the top of the gas burette (A) to the ventilating apparatus at á (see Fig. 2) to catch air which has passed through the animal cage and which is escaping from á.

respired air from that found in normal air. At least two samples should be analyzed from each ten liters of respired air, the average being used to obtain the result.

In withdrawing samples of respired air, care must be taken not to release the clamp at á until positive pressure exists in that bottle.

In operating the ventilating apparatus care must be taken to clamp x, x', x'' when the position of the bottle is to be changed, so that the respired air will not be contaminated by normal air which would pass into it on account of negative pressure which exists in that bottle. It also prevents the KOH in the Geissler bulb from being forced back into the $CaCl_2$ tubes on account of a slight negative pressure existing in the apparatus between the Geissler bulb and the water in the elevated bottle of the respiratory apparatus. This likewise prevents the water from flowing from one bottle of the respiratory apparatus to the other, causing a change of pressure, which is not desired until all connections are made for the change of position of the bottles.

OBSERVATIONS.

On account of the size of our animal cage, small animals, guinea-pigs, mice, and small rabbits, were used

in the experiments. The guinea-pigs and mice were full grown and well nourished. The rabbits were not full grown, but were in good condition.

In comparing tubercular animals with normal animals care has been taken to secure animals as near as possible of the same age. In this case the rabbits were of the same litter. The guinea-pigs were adults and similar in weight at the time of inoculation. In all cases the most virulent sputum which could be obtained was used and postmortem examination performed on the animals

respiratory quotient for all normal animals experimented on. He will note that the range of variation of the respiratory quotient is very considerable, the lowest being .730 and the highest being .986, thus representing almost the complete recognized range of variation of normal animals as influenced by feeding. Note that the lowest respiratory quotient was shown by the animal experimented on December 27; note also that this animal had had nothing to eat for two days. This result is in harmony with the experiments of others upon fasting animals. A study of the table, with special reference to the time of feeding, will reveal the fact that the lower values of the respiratory quotients uniformly occur when the animal has been fed some time before the experiment. The highest value shown was in the rabbit experimented on June 24. This animal had eaten just before the experiment began, so that the one hour and thirty minutes devoted to the experiment represented the time during which the digestive process was most active. The other higher values shown will be found in those animals that had eaten just before the experiment or in those animals which had access to food constantly.

It is a matter of common knowledge that the character of the food has much to do with the value of the respiratory quotient. In herbivorous animals the respiratory quotient may reach one as its highest limit. The reason for this is evident, if we think of the chemical formula for any typical carbohydrate. The oxygen and hydrogen have to each other quantitive relations shown in water, and will require no further oxygen during the combustion or respiratory process. The carbon will form just as many molecules of carbon dioxid as there are molecules of oxygen required in the combustion or the respiration. It must be evident from this that the respiratory quotient arising from the oxidation of carbohydrate within the tissues of the living animal would be the same as the combustion quotient of the same substance when burned in a retort.

The similar study of typical foods will reveal the fact that the combustion quotient is equal to the respiratory quotient for fats but not for proteids. The reason for this is that fats undergo complete oxidation within the body, but proteids do not. The combustion quotient for proteids will then be higher than the respiratory quotient. The grams calorie represented in a proteid is 5,650 per gram of desiccated proteid. The animal body, however, is able to get from this proteid only about 4,000 grams calorie of energy. The difference (1,650) represents the relative difference between the combustion quotient and the respiratory quotient for proteids. The respiratory quotient in animals nourished wholly by proteids varies between .75 and .85. In fats the respiratory quotient is the same as the combustion quotient. The small proportion of oxygen, as compared with the carbon and hydrogen in the fat molecule, reduces the respiratory quotient for this foodstuff to about .7. It has usually been supposed by physiologists that the character of the nutriment, that is whether carbohydrate, proteid or fat predominated, would control very largely the value of the respiratory quotient.

The animals experimented on in this research were fed on carbohydrates exclusively, the rabbit eating cabbage leaves and carrots, while the guinea-pig and mice lived on cereals. The variation of the respiratory quotient noted in column R. Q., Table 1, depends, then, not on the character of the food, but on some other factor. The attention of the reader has been called above to the fact that this variable factor is nothing else than the variation of time of feeding. It may not be apparent at first how the difference in the time of feeding can thus modify the respiratory quotient, but we have only to remember that the animal begins, after a few hours of fasting, to consume his own fat and the circulating proteid of his blood to realize that within a few hours after each meal the herbivorous animal becomes, in a sense, a consumer of proteid and fat.

In a further examination of the observations it becomes necessary to reduce the data to common standards in order to compare with each other things which are strictly comparable. The first step is to express (Tables 3 and 4) the amount of gas exchange per gram animal per hour, Table 3 showing the normal and Table 4 the tubercular animals. Note that Table 3 gives the standardized data of Table 1, while Table 4 gives the standardized data of Table 2.

2. Relative to the amount of oxygen consumed and the carbon dioxid exhaled by animals under observation,

it is interesting to note (see Tables 3 and 5) that the white mouse consumed nearly or quite three times as much oxygen and exhaled three times as much carbon dioxid as did the other animals. The reason for this seems to be that the small animals, and this is true as well of small birds as of small mammals, present larger surface to the atmosphere in comparison with the bulk of the animal than is the case with larger birds and animals. This seems to account for the fact

TABLE 4.—Showing the amount (cubic centimeters) per gram animal per hour, of oxygen consumed and CO_2 exhaled by tubercular animals.

that the respiratory processes are more rapid in the small than in the larger ones.

Attention has been called above to the fact that the time of feeding is a most important element in determining the respiratory quotient. It becomes necessary, therefore, to eliminate the influence of this factor by comparing with each other only observations which represent practically constant conditions with respect to this factor. Table 5 shows in parallel columns the normal animals, divided into two classes, (1) those which had been fed immediately before the experiment, and (2) those which had been fed long before the experiment. Table 6 shows the same for tubercular animals. Note that the data of these tables represent simply the averages of strictly similar experiments on animals of the same species, as combined from Tables 3 and 4 respectively.

A study of Tables 5 and 6 makes it evident that the respiratory quotient of tubercular rabbits which had just been fed is greater than is the respiratory quotient of normal rabbits under the same conditions. The same is true when we consider the result with guinea-pigs. If we examine the respiratory quotient in those normal and tubercular animals which have been fed long before the experiment we must reach the same conclusion.

4. Let us now examine the result with reference to the amount of oxygen consumed and the amount of

TABLE 5.—Showing the influence of feeding on the amount of oxygen consumed and CO_2 exhaled, per gram animal, per hour, and the respiratory quotient in normal animals.

Animals Fed Two Hours or Less Before Experiments.					Animals Fed Twelve Hours or More Before Experiments.

Rabbit	8	1.046	954	.917	Rabbit	5	1.162	.956	.823
Guinea-pig	1	1.182	1.080	.910	Guinea-pig	2	1.298	.995	.738

carbon dioxid exhaled, leaving out of consideration the respiratory quotient.

While fasting, the tubercular rabbit consumed 60 per cent. as much O and exhaled 71 per cent. as much CO_2 as the normal rabbit under the same circumstances. After the consumption of food it consumed 82 per cent. as much O and exhaled 85 per cent. as much CO_2 as the normal rabbit under the same circumstances. This shows:

(*a*) That during all circumstances as to feeding, the tubercular animal consumes relatively less O and exhales relatively more CO_2 than the normal animal under the same circumstances. Since tuberculosis is a disease in which the animal is continually losing weight, a part of the loss of weight will probably come from the lungs in the form of CO_2 and not so much oxygen will

TABLE 6.—Showing the influence of feeding on the amount of oxygen consumed and CO_2 exhaled, per gram animal, per hour, and respiratory quotient in tubercular animals.

Animals Fed Two Hours or Less Before Experiments.					Animals Fed Twelve Hours or More Before Experiments.				
Animal.	Number of Experiments.	Oxygen Consumed. c.c.	CO_2 Exhaled. c.c.	R. Q.	Animal.	Number of Experiments.	Oxygen Consumed. c.c.	CO_2 Exhaled. c.c.	R. Q.
Rabbit	4	1.002	.930	.926	Rabbit	4	.865	.723	.827
Guinea-pig	1	1.148	1.081	.945	Guinea-pig	2	1.239	.956	.716

be required to support the metabolism of an animal that consumes less food and is less active than a normal animal.

(*b*) During the periods of fasting the tubercular animal consumes less O than the normal animal under the same circumstances. This indicates that the metabolism in the tubercular animal is less than it is in the normal animal. This, from the nature of the effect of the disease, we believe to be true.

(*c*) The rate of consumption of oxygen by the tubercular animal is not as constant as it is by the normal animal.

SUMMARY.

1. Time of feeding causes the greatest fluctuation of the respiratory quotient. Under favorable physical conditions it may rise to nearly 100 after the consumption of food, and may fall to about 70 during periods of fasting.

2. The respiratory interchange of gases is very much greater per gram animal per hour for the very small animals than for the larger ones.

3. Tubercular animals consume relatively less oxygen and exhale relatively more carbon dioxid than do normal animals under similar circumstances.

4. The respiratory quotient is raised under the influence of tuberculosis.

DISCUSSION

ON THE PAPER OF DRS. ADERHOLD AND HALL.

DR. LOUIS C. AGER, Brooklyn, N. Y.—Could the decrease in the volume of oxygen absorbed by a tuberculous rabbit be accounted for by a decrease in the area of absorbing lung tissue? Would a rabbit in the early stages of pulmonary tuberculosis, or with tuberculosis of some other part of the body absorb less oxygen?

DR. CHARLES T. MCCLINTOCK, Detroit—Did Dr. Hall notice any difference in the absorption of oxygen according to the moisture in the air? It is well known that tuberculous patients breathe badly on moist days.

DR. LEO LOEB, Chicago—Did the temperature make any difference in the experiments performed?

DR. F. F. WESBROOK, Minneapolis—I should like to ask Dr. Hall if the infection of his animals was produced by subcutaneous inoculation of the tuberculous sputum and, if so, whether any steps were taken to eliminate possible variations which might result from pyogenic and other bacteria which were in association with the tubercle bacilli. This variation would, of course, be more marked in some cases than in others. For example, if streptococci were present in the sputum inoculated, the effect on rabbits and mice would be much more severe than on guinea-pigs. The site of inoculation might have an influence as well.

I should like to inquire, also, whether concurrent determinations of the nitrogen output were made and whether the loss of body weight mentioned could be accounted for by the changes in the operation of the respiratory mechanism.

I wish to congratulate the authors on their method of employing a second or control tube to gauge the amount of carbonic acid and moisture in the air supplied to the animal, whereby the objectionable feature involved in furnishing them with a perfectly dry air was done away with.

In 1895, in work along the same lines done in collaboration with Dr. Lorrain-Smith, we supplied our animals with air from which both moisture and carbonic acid had been removed. This always seemed to me too artificial and to be the source of possible errors in deductions.

DR. W. S. HALL, Chicago—First, in regard to the amount of oxygen consumed in relation to the amount of lung tissue: these animals only lived a few weeks, and the lungs did not seem to be particularly affected. It was a general tuberculosis, and there seemed to be no decrease in the amount of functional lung tissue.

Second, in answer to Dr. Loeb's question, the temperature was not taken throughout the whole period, but was taken on a number of occasions, and on all of these occasions it was slightly above normal in the tubercular animals.

Third, regarding the humidity: it is a part of the laboratory protocol furnished us weekly by the United States Weather Bureau (Auditorium station) and also determined by our air analysis, but we took no account of this in writing up our experiments. It has, however, not escaped our attention. Dr. Aderhold did not think, from a study of the laboratory notes, that the humidity was of sufficient importance to record it in the published tables. It might, however, add interest to these tables, in excluding humidity as an active factor, in modifying the respiratory quotient, if for no other reason.

Fourth, as to the difference in infection, as spoken of by Dr. Wesbrook: the injection was subcutaneous and, naturally, there was more or less mixed infection, but the little streptococcus infection that followed some of these injections was moderate and did not seem to be the cause of the death of any of the animals used in the series of observations. In these animals the disease seemed to run the usual course of tubercular infection, but in one or two cases Dr. Aderhold reported an animal dying in a shorter time, and evidently of mixed infection, and such animals were not included in the series of observations.

DR. LOUIS C. AGER, Brooklyn—As long as there was only slight destruction of lung tissue, did you form any conclusions as to the cause of lack of oxygen absorption? Was it due to decrease of hemoglobin?

DR. W. S. HALL, Chicago—The relation of the two conditions, loss of weight and decrease of consumption of oxygen, is the puzzling point of the problem. I wish I could answer this question as to how there can be a loss of tissue with a decreased oxygen consumption. If there was as much food taken in during the course of the tubercular infection an increase of oxygen consumption would be necessary to oxidize this food and carry it out of the body. I am inclined to think we could not get a loss of weight and wasting of the tissues, together with a decreased oxygen consumption, unless we had a decreased alimentation. We notice that in tubercular cases this is true, and an evident loss of appetite was observed in these animals. I think this is the only way we can account for it.

THE INTRACELLULAR TOXINS OF SOME OF THE PATHOGENIC BACTERIA.*

VICTOR C. VAUGHAN, M.D.
ANN ARBOR, MICH.

Two years ago, at a meeting of this Association at Atlantic City, and before this Section, I had the privilege of describing some experiments made by some of my students and myself on intracellular toxins. I desire in this paper to make some additional statements on this subject.

By means of the large incubating tanks which I described in a paper read before the Association of American Physicians in 1901, and which are figured in the transactions of that society, I have been able to obtain both pathogenic and non-pathogenic bacteria in large amounts absolutely free from the constituents of the culture medium on which the germs have been grown. In this way I have studied the cell substance of the colon bacillus, the bacilli of diphtheria and anthrax, the *Micrococcus prodigiosus,* and the lemon and orange sarcines. I have found that the cell substance of all of these organisms is more or less toxic to guinea-pigs and rabbits. The toxicity varies with the virulence of the culture employed. The cell substance of the colon bacillus after extraction with alcohol and ether and complete desiccation in vacuo kills guinea-pigs when injected into them either intraperitoneally or subcutaneously in proportions of 1 part of the poison to 45,000 parts of body weight. For rabbits this substance is somewhat more toxic. By heating the cell substance of the colon bacillus for a period not exceeding 30 minutes at a temperature of the water bath with a 1 per cent., by weight, solution of sulphuric acid in water we have been able to split off a soluble toxin which, when injected into animals, causes symptoms and lesions identical with those obtained after injection of the unbroken cell.

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Pathology and Physiology, and approved for publication by the Executive Committee: Drs. Alfred Stengel, L. Hektoen and Frank B. Wynn.

The toxin thus split off seems to be of relatively simple composition compared with that of the whole cell substance, but so far I have not been able to obtain it in a sufficiently pure state to justify an ultimate analysis. The probabilities are that this split product which has this specific toxic action belongs to the class of protomins which were discovered by Miescher and which have been subsequently extensively investigated by Kossel and his students. However, I may note the fact that the toxins obtained in my laboratory by means of dilute sulphuric acid and heat do not give a satisfactory biuret reaction, while protomins of Miescher and Kossel respond promptly to this test. We have also found that the part of the cell substance which remains after hydrolysis with dilute sulphuric acid is still toxic, but much less so than the whole cell substance, or that part split off by the acid. Theoretically I infer from this that the molecule of the colon bacillus contains two or more toxic side chains, only one of which is split off by dilute sulphuric acid, while the other toxic side chain remains unaffected and gives to the residue after extraction with dilute sulphuric acid its poisonous properties.

Probably the most interesting piece of work done in my laboratory during the past two years is that on the toxin of the anthrax bacillus. We have obtained the cell substance of this organism in large quantity and have found that the dead germ substance, when mixed with water and thoroughly sterilized and injected intra-abdominally into guinea-pigs in amounts of from 200 to 300 mg., causes death, and that anthrax lesions are found. By heating the germ substance with 1 per cent., by weight, of sulphuric acid in the autoclave at 110 for 10 minutes, complete sterilization is secured and the acid splits off a substance which, after filtration, is precipitated by pouring the filtrate into three volumes of absolute alcohol. This precipitate when collected, thoroughly washed until every trace of acid has disappeared, dried in vacuo, and pulverized, forms a snow white powder, which is soluble in water rendered feebly alkaline with sodium bicarbonate. This powder, when thus dissolved and injected intra-abdominally into guinea-pigs of from 200 to 300 grams weight, in amounts of 50 mgs. or more, causes death with lesions similar to, if not identical with, those observed after death from typical anthrax. It seems to me that this must be considered the specific toxin of anthrax. All of the theories concerning the modus operandi of germs in causing disease have been applied to anthrax, inasmuch as this has been considered the typical infectious disease. Various attempts have been made to find the specific toxin of this disease.

A review of some of the work that has been done along this line may be of interest in this connection. As early as 1877 Pasteur filtered cultures of anthrax through porcelain and injected the germ-free filtrate into animals without effect, thus showing that this organism does not elaborate a soluble toxin. Some years later Hoffa reported that he had obtained from pure cultures of the anthrax bacillus small quantities of a ptomain which, when injected under the skin of animals, produced the symptoms of the disease and death. At first this substance caused increased respiration and action of the heart. Subsequently the respirations became deep, slow and irregular. The temperature fell below the normal, the pupils were dilated, and a bloody diarrhea set in. On section the heart was found to be contracted, the blood dark, and ecchymoses were observed on the pericardium and peritoneum. Hoffa called this poison anthracin, and later he reported that he had isolated it from the bodies of animals dead with anthrax. These results could not be considered satisfactory. Moreover, several investigators have repeated Hoffa's experiments with negative results.

In 1889 Hankin prepared from cultures of the *Bacillus anthracis* an albumose which, when employed in comparatively large amount, proved fatal to animals, and when used in very small quantity gave immunity against subsequent inoculations of the living germ. Subsequent investigations have failed to confirm Hankin's results. Brieger and Fraenkel reported that they had found a toxalbumin in animals dead from anthrax. In their experiments the liver, spleen, lungs, and kidneys of animals recently dead from this disease were finely divided and rubbed up with water. This emulsion was allowed to stand in a refrigerator for 12 hours, when it was passed through a Chamberland filter and the toxalbumin precipitated from the filtrate with absolute alcohol. Conradi has carefully repeated Brieger and Fraenkel's work with negative results.

Martin grew the anthrax bacillus for from 10 to 15 days in an alkaline albuminate from blood serum, then filtered through porcelain, and obtained from the filtrate the following products: 1. Protoalbumose and deuteroalbumose, and a trace of peptone, all of which substances behave like similar bodies prepared by peptic digestion. 2. An alkaloid. 3. Small quantities of leucin and tyrosin. The most characteristic property of the albumoses obtained by Martin is that their solutions are strongly alkaline, and the alkalinity is not removed by treatment with alcohol, benzol, chloroform, or ether, or by dialysis. The alkaloid was found to be soluble in water, alcohol and amylic alcohol, but insoluble in chloroform, ether and benzol. Its solutions were strongly alkaline and it formed with acids crystalline salts. The mixed albumoses were found to be poisonous only in considerable doses, 0.3 of a gram being required to kill a mouse of 22 grams weight when injected subcutaneously. Smaller doses caused local edema and a somnolent condition, from which the animal recovered. Larger doses produced more extensive edema and the somnolence deepened into coma and terminated in death. The alkaloidal body reported by Martin is apparently not identical with that obtained by Hoffa. Marmier grew the anthrax bacillus in a peptone culture medium and reported that he had obtained a toxin from sterilized cultures of these growths by precipitation with ammonium sulphate.

The most recent work on the anthrax toxin, before that done in my own laboratory, was reported in a very exhaustive paper in the *Zeitschrift für Hygiene* by Conradi. This investigator reviews extensively the literature of the subject, and adds experiments of his own. From all the evidence that he could obtain at that time, Conradi came to the conclusion that the anthrax bacillus does not produce either an extracellular or intracellular toxin. If the work in my laboratory be confirmed, it will show that the anthrax toxin is a constituent of the bacterial cell, from which it can not be removed except by certain chemical disintegrations of the cell substance. A few experiments made in my laboratory indicate that the part of the cell which remains after extracting the above mentioned toxin with dilute sulphuric acid is also toxic. However, the extent to which it is toxic has not yet been determined. Many interesting questions arise in connection with this work, and I am tempted to enter into the discussion of some of them, but will forbear until I have amplified my experimental researches.

Our work with the diphtheria intracellular toxin is exceedingly interesting. From the experiments that we have made we conclude that the intracellular toxin of diphtheria is not identical with the soluble toxin. Commercial diphtheria antitoxin protects animals against the soluble diphtheria toxin, but fails to protect against the intracellular toxin. This offers, apparently, a plausible explanation for the fact which has been observed by others that natural immunity to diphtheria toxin may be possessed by animals which are not immune to diphtheria infection.

The cell substance of the *Micrococcus prodigiosus* and of the lemon and yellow sarcines are toxic in varying amounts, depending largely on the extent to which the cells are purified from the mucilaginous substance surrounding them in the culture medium.

The full paper, of which this is an abstract, has been prepared for the Rockefeller Institute, and will doubtless be published in the reports of that organization.

ANGIOSARCOMA OF THE LIVER.

REPORT OF A CASE.*

J. C. COOK, M.D.
CHICAGO.

NARRATION OF CASE.

A child was presented at my clinic, Aug. 5, 1901, aged 3½ years; female. The first indication to the mother of any trouble was noted five weeks previous, when she observed a small tumor, or hard lump, in the right iliac region and a week later a similar growth was noticed in the corresponding location in the left side. Both grew until they met. About this time the child vomited some, but this did not persist. The bowels became constipated and the abdomen distended, and she began to lose weight.

Examination.—The following clinical findings were noted: temperature normal, pulse 110 to 120. Urinary examination revealed nothing. The child presented a markedly distended abdomen, measuring twenty-five inches at its greatest circumference, which increased to twenty-seven inches August 28. No blood had escaped from any of the cavities; no history of malignant disease could be obtained; white blood corpuscles 12,000, hemoglobin 50 per cent., red blood corpuscles 3,600,000. The child presented an emaciated appearance and wore an anxious expression.

Operation.—August 6 an exploratory incision was made by Dr. Allen B. Kanavel which revealed a tumor filling the entire abdominal cavity, grayish white in appearance, soft and friable, evidently malignant in character, that could not be separated from the ovaries, uterus or kidneys. The latter organ was believed to be its origin because of the relative frequency with which it is attacked. The laparotomy revealed the absence of fluid in the abdominal cavity. Further operative procedures were abandoned, as it was believed they would not increase the chances of recovery. The abdominal wound was closed and united rapidly.

Subsequent History.—The child was sent home, no change occurring worthy of note except that on August 20 the right leg became edematous. She died on August 28 under a diagnosis of inoperable sarcoma. The entire course from the first symptom to the end was two months.

Autopsy.—I am indebted to Drs. Kanavel, Richter and Springer for the following postmortem report: The body was greatly emaciated, the right leg markedly, and the left leg slightly, edematous. About two quarts of clear serous fluid escaped on opening the abdomen.

The tumor appeared to be both extraperitoneal and intraperitoneal, as if it had grown under the peritoneum to both sides, then had extended up through the mesenteric attachment in the median line and on the right side, for here the growth was restricted into a sort of neck. Once well up into the mesentery, it expanded and broke through into the peritoneal cavity, growing for the most part down into the pelvis so as to give on palpation early in the course the suggestion that it originated here, the irregularity of its growth leading the mother to find two nodules, one on each side. The two portions of this dumbbell-shaped mass are about the size of a ten-year-old child's head, and it is soft like a child's brain. On cut section pulpy, whitish or bloody areas arise above the surface, the latter being numerous and due to extravasated blood from the numerous newly-formed blood vessels present. Here and there bands of firmer tissue running in every direction serve to bind the mass together, while numerous peritoneal bands on the surface, stretched tight, increase the verrucosity of the lobulated mass. The aorta and vena cava lie behind. Between the two masses were found the kidneys, connected by a fibrinous band giving the appearance of a horseshoe kidney, connected inferiorly by an isthmus of flattened kidney tissue an inch and a half in width and from an eighth to a quarter of an inch in thickness, gradually thickening and widening at each end to unite imperceptibly with the lower pole of each kidney, coming up as high as the pelvis. The upper poles are free. The capsule of the kidney covers, both anteriorly and posteriorly, all of the left and the upper pole of the right, but inferiorly on this kidney it extends out to include the tumor growth which grows by a prolongation from the lower pole, a neck of kidney tissue changing into tumor tissue so gradually that at no place can one say, macroscopically at least, here is kidney tissue and there adjoining is tumor growth. This neck is about one-half inch in diameter and one-half inch long.

The arteries and veins come in from each side to the upper part of the kidney, the vein being superficial. They bifurcate to go dorsally and ventrally to the pelvis of the kidney; then ramify on the isthmus uniting with the corresponding vessels of the opposite side. The ureters are separate below, lying ventrally to the lower pole, and are connected by a communicating branch lying in the kidney tissue along the upper part of the isthmus. They run down between the intra- and extraperitoneal tumors. The kidneys are of normal size and the pelvis is not dilated.

The omentum was filled with metastatic growths varying in size from a pea to a walnut. The same may be said of the iliac mesentery. No other metastases were found either in the organs of the body or in the lymphatic system, bones not being examined. Spleen, heart, liver and pancreas were entirely negative; slight emphysema of lungs. The tumor mass, with kidneys attached, weighed seven pounds.

Says Ziegler: "A sarcoma is a connective tissue tumor in which cellular elements are much more prominent than the intercellular substance. A typical sarcoma, as the name implies from the Greek, is fleshlike in consistency. In appearance it is generally more or less rounded, often enclosed in a capsule, but may be irregular, infiltrating and unencapsulated. Their consistency is soft or hard, according to the number of cells and amount of intercellular substance composing them."

ETIOLOGY OF SARCOMA.

"The frequent occurrence of sarcomata in young persons," says Conheim, "is among the evidences pointing to a congenital origin." Traumatism and inflammation play some part, either in developing a lesion from which it may have an origin, or stimulating a new growth from a latent sarcoma.

No specific form of bacteria has been demonstrated, yet the parasitic theory has many adherents in recent years. Experiments with implantation of the disease in animals have been unsatisfactory. Some relationship has been traced between sarcoma and syphilis (Stengel). The seat of the sarcoma is from pre-existing connective

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee: Drs. Edwin Rosenthal, H. M. McClanahan and Samuel W. Kelley.

tissues and may arise in nearly any organ or structure of the body.

THE VARIETIES.

It is essentially malignant in character and tends to recur after removal. Metastasis occurs through the circulation. The degree of malignancy varies greatly. The small round cell and melanotic varieties are the most dangerous. The exact influence of sarcoma on metabolism is unknown, yet it is a well-established fact that sarcomatous growth is injurious to the general health, as is shown by the marked emaciation, anemia, leucocytosis and the sometimes existing irregular fever. The structure of sarcoma cells is round, cylindrical and spindle-shaped. The spindle-celled sarcomas are harder than the round cell. The round cell variety may be almost entirely composed of spherical cells, large or small in size. These enter into combinations in various ways and are modified by their combinations and the structure in which they are located.

Stengel, in discussing tumors of the kidneys, says that sarcoma is the most frequent malignant tumor. It may occur congenitally or in later life. The multiform character of sarcoma of the kidney suggests an embryonal origin and it is not unlikely that the primitive Wolffian bodies are the starting point of the disease.

The special variety of sarcoma to which the specimen from this case belongs is known as an angiosarcoma, or more correctly "hæmangio sarcoma." In this variety the sarcomatous proliferation begins in the adventitious coat of blood vessels. The tissue of the tumor in typical cases is almost wholly composed of a tangle of vessels whose walls are surrounded by heavy masses of cells which extend even as far as the endothelium. Such a tumor, therefore, is made up essentially of thick-walled cellular tubes which partly follow an independent course and partly unite with other tubes by an anastomosis which gives rise to a complicated mass of twisted and interwoven cords. However, it should be mentioned here that in both endothelium and angiosarcoma the alveolar and tubular structures may be wholly lost in places through the diffused manner in which proliferation takes place. Angiosarcoma occurs in the brain, kidney, testicles, lymphatic glands, breast, skin, bone, thyroid and liver, although it is a very rare occurrence in the two locations last mentioned.

THE RECOGNITION AND PROMPT REMOVAL OF POSTNASAL ADENOIDS IN CHILDREN.*

LOUIS J. LAUTENBACH, A.M., M.D., Ph.D.

Surgeon-in-Charge of the Philadelphia Eye, Ear, Nose and Throat Institute; Nose and Throat Physician to the Odd Fellows' Home.

PHILADELPHIA.

The importance of the consideration of our subject is evident when we observe the divergent views presented by different authors as to the instruments to be used in operations and the varying ideas as to anesthesia. That the subject is still uppermost in the mind of the specialist is evident from a consideration of this year's programs of the Section on Laryngology and Otology, where three papers out of a total of thirty-three are presented on the growths in the nasopharynx, and of this Section on Diseases of Children, in which three papers out of a total of thirty-nine are devoted to the same subject.

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee: Drs. H. M. McClanahan, Edwin Rosenthal and Samuel W. Kelley.

FREQUENCY AND CAUSES.

As to its frequency, opinions of authors are much at variance. Ingals of Chicago reports but 2 per cent. out of ten thousand private chest, throat and nose patients, while Frankenberg reports 59 per cent. in the 158 inmates of the Deaf and Mute Institute at Prague. Some writers incline to believe that adenoid enlargements are not more common in deaf mutes than in the more normal members of the community, and that when they are present they have no causative effect on the deafness. Yet Arslan and others report cases where they have succeeded in restoring the hearing by proper removal of the growths followed by appropriate after-treatment.

We all know that children are peculiarly prone to these growths; that they are apt to arise in the second, third and fourth years; that occasionally they seem to be congenital; that in adults the tendency to proliferation and closure of the lymphoid tissues appears less often, and the disease is much more rare, but yet exists more frequently than is popularly supposed.

I believe that most authors agree that it occurs more often in boys than in girls. I can not say that this has been impressed on me, but I do know that it is a very frequent disease in children, and while I have not thoroughly analyzed my cases, I am sure that in my work I have observed it in over 10 per cent. of all the children I have treated in my private practice, and during one week of May, 1902, I removed adenoids from five children, while there is rarely a week that I do not remove one or more of these growths in my private work.

In regard to constitutional predisposition, most authors agree that there is an hereditary tendency; there are some who do not concur that the lymphatic or scrofulous diathesis has any bearing on the case. There is no question that they are more frequent in the weak, the poorly nourished; those who give evidence of the strumous diathesis. Children who are the victims of scrofula, syphilis, tuberculosis, anemia, chlorosis and chronic malnutrition are most prone to develop these tumors. In addition a very moist climate is a powerful agency in precipitating the condition. In my own experience I can not say that I have ever found these adenoid growths in a child that, to me, seemed the picture of health. It is, however, to be considered that in some few cases it may have originated from some local disorder in the nasopharynx, the resulting ill health being subsequent to the growth.

A factor in proving that the enlargement is usually not a local condition is that in nine cases out of ten the faucial tonsils also are enlarged and diseased. This fact has been noted by numerous writers, among others William Meyer, Morell Mackenzie, H. Lennox Browne and Joseph Gruber. There appears to be a tendency to disease in various other lymphoid structures.

DIAGNOSIS.

As to the method of making the diagnosis, the symptoms observed are usually sufficient—the difficulty of breathing, the mouth breathing, the open lips, the vacant countenance, the loss of memory, the stammering, the poor hearing, the dead, flat, muffled voice, the cough, the pinched wing and flattened bridge of the nose, the flat chest, the general lack of health and vitality, and the enuresis and indigestion, and numerous nervous reflexes, all go to make up a picture which when present can not be mistaken. When the diagnosis is a probable one, but not certain, it can be made fixed and definite by examining the rhinopharyngeal space by means of the index finger of the right hand inserted through the

mouth back of the soft palate. The nature of these growths is simply that of hypertrophies of the normal lymphoid tissue, and containing varying amounts of fibrous and connective tissue. The masses are sometimes single, lobulated, clustered or stalactitic; sometimes soft, again hard or tough; sometimes very friable, again encapsulated; sometimes occupying the vault only, again extending far over to the sides involving the entire rhinopharynx and completely occupying the fossæ of Rosenmüller as well as the eustachian tube orifices. These growths seem to predispose their subjects to numerous diseases. They are constantly troubled with catarrh, always taking cold in the head; they usually develop tonsillar and other throat diseases. They are peculiarly liable to hay fever, bronchitis and pneumonia. They almost always have some insufficiency in the heart's action. They often develop nervous affections, such as enuresis and asthma and even chorea and epilepsy; paroxysmal sneezing is most common. They are very liable to all the acute fevers, such as diphtheria, scarlet fever, measles, etc.

Diseases of the ear follow in many cases; acute inflammation of the middle ear and mastoid is by no means uncommon, and deafness is often present. Friederich explains this as follows:

> Any and all diseases of the nose and post-nasal space which are followed by obstruction of the nasal passage lead to passive hyperemia in the mucous membrane, which in turn produces occlusion of the eustachian canal. . . .
>
> The obstructions may be situated in the post-nasal space, and may take the form of hypertrophied pharyngeal tonsils, tumors, syphilis, or tuberculosis occluding the posterior nares. Hence the recognition and removal of any obstacle to nasal respiration should constitute an integral part of every examination and treatment of the ears. There can be no hope of curing the ear affection before the causes which are responsible for the congestion of the mucous membrane have been removed and the permeability of the tube has been restored. If I have included hypertrophy of the pharyngeal tonsils or adenoid vegetations among the diseases which produce hyperemia and swelling of the mucous membrane, with occlusion of the tube by interfering with nasal respiration, it is because I believe the occlusion is due to a general "adenoid habit" of the nose and pharynx, rather than to the direct mechanical intrusion of the pharyngeal tonsil. The "adenoid habit" manifests itself in the rhinoscope image as a hyperplasia of the entire lymphatic ring of Waldeyer; the follicles in the posterior pharyngeal walls and in the longitudinal folds on each side of the pharynx are more numerous, and are intensely red and swollen. Hyperplasia of Rosenmüller's crypts and of the anterior fold of the tube may develop as the manifestation of a general hyperplasia of all the lymphatic elements entering into the formation of the so-called pharyngeal lymphatic ring; hyperplasia of these structures necessarily favors the occlusion of the tube by compressing the orifice.

Disorders of the digestive apparatus are quite the rule; the condition is precipitated by the usually profuse discharge which flows down the posterior wall of the pharynx, most of which finds its way, with children, into the stomach, where it sets up irritation through the processes of fermentation. Another factor seems to be the lack of the usual quantity and even the healthy quality of the buccal saliva. In addition such children are apt to bolt their food because of the lack of nasal breathing preventing thorough and comfortable mastication.

The rhinopharyngeal region is subject to much variation. The bones at the base of the skull which serve as the roof of this space vary much in their growth and development; in some the space is narrow and high, again it may be shallow and broad, or it may be flat or well rounded in either of these cases. Its usual appearance is somewhat like a section of a long cone, the apex of the cone being above and arched. Were this invariably so instrumental operations would be much simplified, and would be followed by more uniformly good results. As a matter of fact we never strike two of these cases exactly alike; there are constant variations.

The most serious and the most frequent of these variations is where you find the sides of the rhinopharyngeal walls separated from the central or posterior wall by hard, bony ridges, which in some cases extend up into the extreme upper and anterior terminus of the pharyngeal vault. I should say that in children this peculiarity is observable in perhaps two out of every ten cases, and its presence is a serious interference to instrumental operations, whether by the forceps or the curette, but especially to the former. Not infrequently do we find cases which have been thus operated on where parts of these bony ridges have been torn away, and yet where part of the growth lying down in the hollow between these ridges has not been removed; in other words, necrosis was going on simultaneously with enlargement of the adenoid growth after the operation had been performed and pronounced completed.

These bony ridges are apt to start just above the level of the soft palate and extend usually into the vault, dividing the bony walls into a central and two lateral sections. In other words, there are three sections of a cone arched above.

METHOD OF TREATMENT.

The old, passive, medicinal treatment is nowadays very rarely attempted, but in some measure, of course, it comes into play in every case in the preparation of the patient for operation. The use of cleansing alkaline, antiseptic and astringent washes, and the use of drying and astringent powders, as well as protective or medicinal oils and salves, are all necessary for this purpose, and they may in addition be useful in allaying the symptoms as well as in restoring any lack of confidence the little patient may have in his doctor. It gives each an opportunity to study the other. Such treatment may perhaps occasionally cure a case, but usually it will only improve the symptoms.

Formerly some advised that the only necessity in these cases was to keep the parts clean and give the growth a chance to atrophy and disappear. Now this dependence on faith and cleanliness is not to be advised. It is a relic pure and simple and has no place in present-day treatment. The only conclusion to be reached is to remove the growth at the earliest period practicable, and to do it thoroughly, and to avoid exposing the little patient to any unnecessary risk.

The removal of these growths by electricity has been advised by a number of writers, Burnett and others advising the cautery points, Sajous using the cautery loops or snare, on account of the supposed painlessness and convenience, as well as the almost uniform results. These methods, however, have not been followed by good results and are rarely used.

It is now understood that whatever method is employed it must give assurance of the entire removal of the growth and a reasonable certainty of its non-return.

ANESTHETICS.

Before considering the operations proper, which conform in the main to the foregoing proposition, we should consider for a moment the subject of anesthetics, local and general.

Local anesthetics, such as cocain, holocain and eucain, can be used by application through the nose and throat, and will do much to dull the sensibility of the parts if you can only have the child held perfectly steady; no doubt all the necessary operative procedures could be done without any very serious difficulties. Even the Meyer ring curette or the Gottstein curette, the guillotine, or any of the numerous forceps could be employed without subjecting the child to serious pain if nervous apprehension and fear were not a factor.

As a matter of fact, however, children can not hold well for such serious and menacing operations, and it is because of this lack of control on the part of the child that most of the operators have been driven to use general anesthesia. Now the operators in this field are by no means agreed as to the best and least dangerous anesthetic to use. Many advise chloroform, and as many condemn it. Numerous deaths among these cases have been reported from its use. Ether is advised and used by many, and then once in a while one of our little people takes the long sleep. Bishop uses bromid of ethyl; others find it dangerous. Nitrous oxid and nitrous oxid administered with oxygen is used, but while it is apparently the safest (13 deaths in a record of 750,000 administrations) it has the disadvantages that doctors can not readily administer it, and its effects are so evanescent. The A. C. E. mixture has been employed. It also has numbered its victims in our adenoid operations.

It is a matter of common knowledge that our adenoid tumor patients are peculiarly susceptible in the cardiac region; they are more liable to syncope and death without premonition. It is unfortunately true that while some of these cases are reported, and they are now not an inconsiderable number, yet by far the majority of these results are never put into print, and we have no means of knowing just how serious is the problem that confronts us. I venture to say that if accurate statistics could be obtained general anesthesia in these cases would be almost discarded. Henry Gradle says:

> Narcosis makes the operation more formidable and necessitates more assistance. It does not in any way permit a more thorough operation, as most of the relapses which the writer has seen had been operated previously by others, and by himself under anesthesia. The pain in well-arranged operations is not sufficient to necessitate the superfluous risk of an anesthetic. It is only in cases of unruly children from whom active resistance must be expected that narcosis becomes necessary. Narcosis is also preferable when the faucial tonsils are to be excised at the same sitting, as this triple operation is usually too severe a tax on a child's endurance.

METHODS OF OPERATION.

Coming now to consider the various methods of removing these growths, we have first the method of William Meyer, who worked through the nostril with a ring curette while the index finger of the other hand was in the rhinopharyngeal space, the jaws being kept apart by a gag. This has the advantage of an exploring finger constantly present during the operation, the disadvantage being the employment of a general anesthetic.

The operations by the various curettes, such as the Gottstein, Hartman, Beckman and numerous others, are performed under an anesthetic and have the disadvantage that you do not know exactly what you are doing and what you are not doing. You may take away too much or too little; you usually can not completely clean out the fossæ of Rosenmüller, nor can you easily clean out the vault; and again, you may damage the bone and soft structures, especially should the case be one of the anomalous formation of bony longitudinal lateral ridges. The Gottstein and other curettes are not infrequently broken in these cases. In the *Laryngoscope* (May, 1901) two such cases are reported in the personal work of C. R. Holmes and H. S. Garlick. Unless the parts are examined by the finger after this operation a surgeon can not be certain of having finished the work.

Guillotines, such as those of Schutz and Gradle, have the same disadvantages, except they are not so apt to cause injury, but in most cases they are as ineffective as the curettes, or more so.

Forceps, such as Loewenberg's lateral, or Schutz's anteroposterior, and their numerous modifications, have, in the main, the same objection as the pharyngeal curettes. They, however, have the decided advantage that one can rarely cause quite as much damage with the former. The amount of power which can be, and often is applied to these parts by means of the curette is practically limitless. As above observed, numerous cases are constantly occurring where the curette is broken during the operation. Outside of this advantage all the other disadvantages encountered with the curette pertain in using the various forceps.

THE FINGER NAIL METHOD.

There is another method of which I want to speak more at length; a method which can be used in connection with general anesthesia, or, as I prefer, with local anesthesia. Numerous operators, such as Dalby, Capart, Bezold, Lennox Browne, Guye, Kyle, Newcomb, J. L. Gibson, Beverly Robinson, Pritchard, Baber and others, have used and advised the finger nail, or modification of it, by attaching a sharp steel piece to the index finger, the nail or metal acting in each case as a curette. This method has, of course, the advantage that the operator knows all the time just what he is doing; he can explore all the recesses and remove all the enlarged tissues without injuring any of the normal structures. It has the additional advantage that there is no necessity for the administration of a general anesthetic, and thus the needless jeopardizing of human life is avoided.

According to Sir William Dalby, "The diagnosis of adenoid vegetations can only be made with certainty by digital examination, as this alone gives absolute certainty as to their localization, size, extent, form and resistance." As opposed to this I quote Emil Mayer: "Why should you put your finger up there and simply hurt the child for no reason whatever?" I take it as a self-evident truth that when we have a means of being certain of the presence of such growths and can so readily learn their exact location and their nature, it is wrong to neglect this knowedge and to operate with cutting instruments in the dark, where we can not see what we are doing, and using them with perhaps enough force to do positive damage.

How easy it is, on making this digital examination and learning the condition of this region, to at once, as soon as the pathologic condition is ascertained, to remove the enlarged thickened tissues.

Whenever I suspect the presence of these growths, and have obtained the confidence of my little patient sufficiently, I ask the child to open its mouth, saying that I want to feel something inside, and then, without any display of curettes, forceps, etc., I enter the index finger of the right hand with the nail hardened by dipping it into alcohol or reinforced by my jointed artificial finger nail into the child's mouth and feel the condition of the parts in the nasopharynx and remove at once all diseased and enlarged structures, in many cases finishing the entire operation at once.

METHOD OF OPERATION BY ARTIFICIAL OR NATURAL FINGER NAIL.

In order to indicate to you how quickly and yet how thorough the entire procedure is, I will try and detail to you the various steps in the treatment, examination and operation. Being suspicious of the presence of the thickened adenoid tissues I examine the nares and throat thoroughly but gently, and cleanse both cavities thoroughly with sprays, washes, gargles, etc. When these are thoroughly cleansed I seat the child in a revolving arm chair with a spittoon on patient's left hand, and having thoroughly cleansed my right index finger, and having dipped it in alcohol, I put two or three turns of a one-inch adhesive plaster over the first phalanx of my right index finger, and still further protect it by putting over it two or three turns of a doubled two-inch roller bandage, the end of which is secured by making one turn about the wrist, and as you are about to make a second turn pass the free end under the turn already in position. Standing on the right of the patient I lightly put my left arm about the child's head, holding his head against the lower part of my chest; tilting his head a little forward, I insert the right index finger on the right side of the jaw as far back as possible—not using any gag to keep the jaws apart—and quickly carry it back of the soft palate up into the nasopharyngeal cavity, clearing out all the thickened and overgrown tissues at the vault and posteriorly, in the fossæ of Rosenmüller and at the eustachian tube entrances. While doing this the left arm clasps the child's head more and more firmly while bending it forward over the spittoon. All the thickened tissues found are scraped out until the surfaces feel smooth and natural. In the eustachian region I especially press on the tissues in order to overcome any infiltration or congestion. I do not leave the cavity until I am convinced that all the diseased tissue has been removed, or I am convinced that my own finger nail is not strong enough to cope with the form of tissue present, or there is evidence that the blood and detritus are interfering markedly with the child's breathing—these two latter conditions are very unusual in their occurrence, and should they occur it means that either the same day or the next, if possible, I will again enter the cavity and, if necessary, with a steel finger nail remove every bit of diseased tissue discoverable. The entire operation rarely takes more than a minute, and is usually followed by very little hemorrhage.

AFTER-TREATMENT.

After the operation I clean out the throat and nose carefully, use some soothing ointment in the nose, and advise that liquid albolene or mentholized oil be used in the nose and throat at home. In a few days I examine the region, when, if healing has been perfect, the nasopharynx will feel smooth and soft, and there will be little or no danger of recurrence, and if everything is well I may, perhaps, re-examine after a further period of three or four days, if urged to do so by the parents or the physician, but I do not think this necessary unless there be untoward symptoms.

This operation avoids all dangerous procedures, it causes very little pain and it is done without the dangers of general anesthesia; it requires no gag and no display of instruments. While it is simple it is thorough; it is scientific, inasmuch as we verify each step of our proceedings; it is done with the usual antiseptic precautions, and it does not leave the irregular roughened edges usually present after most operations by other methods. In other words, it removes all the pieces and does not allow shreds to remain here and there.

As for a recurrence, it is comparatively rare when the method has been thoroughly carried out, as it more effectively removes the last vestige of affected tissues than can be done in any other way.

Personally, I have many times performed the operation by the above method where previously one of the other methods had been tried with general anesthetic, and in not a few have found considerable cicatricial obstructive tissue around the eustachian orifices and occasionally exposed bone, and often remnants of the lymphoid growth.

Whatever the operation employed, it is absolutely necessary in every case to know the exact condition of the rhinopharynx after the operation. I fear that too often this is neglected, and this is responsible for many of the cases that recur early after the operation. This digital examination should never be neglected.

The after-treatment of these cases is simply that of the catarrhal conditions invariably present plus the treatment of the open wound of the nasopharyngeal vault. Mentholized oil and camphor preparations with alkaline washes and antiseptics are the most important.

CONSTITUTIONAL TREATMENT.

As to the constitutional measures to be employed, it is my opinion that their use is never to be neglected. If syphilis, tuberculosis, scrofula, chlorosis, anemia or digestive or nervous disturbances exist in connection with this growth they must receive appropriate and constant attention.

Cod-liver oil and syrup of the iodid of iron will, on the whole, be most frequently employed. In rachitis and some other cases, phosphorus will be of special advantage, while the hypophosphites and arsenic and the chlorid of iron will frequently come into play. Many of our patients will need saline, alkaline and lithia waters. They will all require plenty of exercise and fresh dry air and sunshine. Their skin clothing should be pure wool but light in weight, the weight and thickness of the outer garments being regulated according to the weather. They should have frequent baths, warm or cold, or both, as the exigencies of the case require. The avoidance of all heart sedatives, such as coffee and tea, is a necessity. The food should be plain and nutritious and should be ample in quantity.

CONCLUSIONS.

Summing up the conclusions which we have reached we find:

1. That the disease is a very frequent one, especially among children.
2. That it is relatively much more common among the poorly nourished and those suffering from constitutional and nutritive disturbances, and is rarely observed among the apparently well.
3. That it is usually found in connection with enlarged pharyngeal tonsils.
4. That it is most frequent among deaf mutes.
5. That its presence is usually determined by the symptoms, but digital examination is both easy and certain.
6. That its presence causes most serious local and general derangements.
7. That its presence predisposes to numerous diseases.
8. That the treatment must be operative.
9. That the operation should be done without general anesthesia.

10. That the finger-nail operation is the most thorough, as well as the most safe.

11. That the rhinopharynx must be examined after every operation.

12. That the finger-nail operation is less likely to be followed by recurrence than the more serious operations.

13. That constitutional treatment must be thoroughly instituted in all these cases in order to overcome the predisposing cause of the growth.

1723 Walnut Street.

DISCUSSION.

Dr. W. C. Hollopeter, Philadelphia—I have always felt this was a subject which had been slighted by the pediatrist. The operation appears to be a cardinal necessity, especially when the sense of hearing is disturbed and the child sleeps with his mouth open, also when swallowing is followed by rapid and inefficient mastication. The author has covered the ground very admirably, and has simplified the surgical treatment. I think the majority of those following this special line of work are inclined to believe that the operation is more satisfactorily done without anesthesia and with the natural or artificial finger nail The artificial finger nail exhibited by the author seems to me rather large; indeed, it is often rather difficult to introduce one's own finger. I should like to have an expression of opinion concerning the use of bromid of ethyl, as Dr. Bishop uses it, as an anesthetic in these cases.

Dr. S. W. Kelley, Cleveland—I have been pleased with the terse statements of this paper. What has been said by him about the number of instruments being indicative of an operation being either very easy or rather difficult applies also to the question of posture during operation and the use of anesthetics. In one case you may choose one posture for the patient; in another, another. But posture may vary according to the fancy or the habit of the operator, or be determined by the question of anesthetics. You may find it convenient to have the patient held in the lap of an assistant, while another holds the head and, perhaps, the gag. You may lay the patient down, with the head hanging over the end of the table. You may take his head under your left arm, or you may simply stand him up against the wall, and so on, according to the case you have to deal with. With some patients a local anesthetic can be used, and there is no trouble, while others can be operated on easily without any anesthetic. In some cases it seems to be impossible to do this operation without general anesthesia, because of the temperament or lack of training of the child. He may be too unruly, or he may be too timid. In some cases a general anesthetic would be contraindicated. As a rule I do not like to use cocain in children. And, notwithstanding all that has been taught about the safety of chloroform in childhood, I have on four occasions met alarming symptoms from its use (not for this operation). So that I do not resort to chloroform unnecessarily I prefer to do this operation when possible without an anesthetic.

The curette with a handle is a powerful instrument, and I believe a great deal of harm is occasionally done with it. Some operators proceed to use this powerful instrument as if they were about to remove plaster from a wall. Whenever possible I use my finger, and I find it a great deal better than the use of an instrument. Of course there are growths that will yield only to a sharp edge. It is just like the question of using the finger or the curette when it becomes necessary to remove the secundines in a case of miscarriage. I like the artificial finger nail exhibited, but I think the steel blade is too long and must interfere with the turning of the instrument. I prefer to use a narrow artificial finger nail, which slips under the natural finger nail and is guided by the palmar surface of the finger. Any of these instruments will occasionally pull off the finger; hence, I feel safer when a turn of bandage is taken through the last ring of the instrument and is then wrapped a few times around the finger or hand. This also has the advantage of preventing the child from biting the operator's finger.

Dr. H. L. K. Shaw, Albany, N. Y.—I am in favor of general anesthesia for the adenoid operation, and I have witnessed the bloody operations done in England and some other places, to which reference has been made. I also believe that one can do very much better with the curette than with the finger nail. I use ether as often as chloroform, and just as soon as the operation has been done the head of the patient is held downward to allow of the escape of blood.

Dr H. J. Rock, Aberdeen, S. D.—Is it not a general principle that chloroform is the least objectionable anesthetic, particularly in the case of children? In a fairly extensive experience I have used chloroform, taking plenty of time to secure anesthesia by this means, and I have seen no harm from its use in this way. As soon as the operation is done the child is turned on the side, with the head low.

Dr. J. F. Klinedinst, York, Pa.—My work is limited to the treatment of eye, ear, nose and throat diseases, and, hence, I do many of these operations. When the child is so unruly that an anesthetic must be used, I prefer chloroform. My experience has been that of many others, i. e., that chloroform is more dangerous in this operation than in others, though we know, of course, that children stand chloroform well. I have not had any fatal cases, but in some the symptoms have been very alarming, so that I do not like to use it. I have used frequently a combination of cocain and adrenalin chlorid, and it seems to be a good one, because adrenalin is known to be a powerful heart stimulant and will counteract, to a great extent, the depressing action of the cocain. Moreover, the adrenalin, by its astringent hemostatic action, lessens the amount of hemorrhage. Why chloroform is dangerous I can not say, unless it may be that the chloroform is not given to the extent of abolishing all reflexes.

CYCLIC VOMITING IN CHILDREN,

WITH REPORT OF CASES.

THOMAS C. ELY, M.D.
PHILADELPHIA.

All neuroses necessitate an exclusion of organic disease, a most difficult task, and an appreciation of an unusual excitability of the nervous system. Of all the various gastric neuroses, secretory, sensory and motor, with their protean manifestations, none are subjects of greater interest than the motor and, though perhaps of less frequent occurrence, none of the motor of more interest than cyclic vomiting.

MECHANISM.

The mechanism of vomiting includes a vomiting center, situated in the medulla near the respiratory center, from which impulses are sent to the diaphragm by the phrenic nerves, to the stomach and esophagus by the pneumogastric and the abdominal muscles by the intercostal nerves. The complex act consists in an inspiration, the glottis closing, the diaphragm contracting the longitudinal fibers of the stomach opening its cardiac orifice, when contraction of the abdominal muscles completes the act, forcing out the stomach contents. The muscles of the diaphragm, of the abdominal walls of the stomach itself, require simultaneous contraction and must be co-ordinated by a relatively strong nerve center. The process is almost physiologic. Act of the will quite controls eructation, or belching of gas from the stomach and, in some instances, regurgitation or bringing up liquid or solid food from the stomach. Individuals have been able to vomit at will.[1]

In the condition known as merycism or rumination swallowed food is returned and chewed over again. Poorly masticated food may be returned and even enjoyed at will, says one writer.[2]

With these strange exceptions, however, unlike a physiologic process, the nervous and vascular systems are always reduced in power, probably not only by the act, but by the morbid process which produces the condition

acting on other parts of the nervous system than the vomiting center.

CAUSES.

The differentiation of the causes of vomiting in children frequently presents difficulties. The causes are varied; children give little or no history and the practitioner must grope his way much as the veterinarian. Called for the first time, or in the first attack, to a child with excessive vomiting, with little or no history, we wish to call attention to a class of cases to which such vomiting may belong, and the differentiation of such cases from other attacks of vomiting in children.

The attacks which are herein described occur in gouty and neurotic children and are due to toxins from faulty metabolism and faulty kidney elimination. The attacks are distinct neuroses, being due to the action of a toxin on the vomiting center in a predisposed subject.

Such neuroses have been described at length in literature by Holt,[3] Rotch,[4] Pepper,[5] Griffith,[6] Gee[7] and other writers. The distinctive features of this gastric neuroses (cyclic vomiting) is that it occurs in a certain type of children, gouty and neurotic.

SYMPTOMS.

Cyclic vomiting has been likened to migraine in its tendency to recurrence or periodicity. Prostration is extreme. Death has been reported in two instances.[8] One other case of death unreported has been brought to my notice by Dr. C. Seltzer, where all known remedies were of no avail.

The vomiting is excessive, severe, protracted, and nothing can be retained by the stomach. Thirst is likewise excessive and distressing. There is no connection in an attack with diet or indigestion. There is generally a fever of indefinite type.

Abdominal symptoms are quite immaterial and varied. The abdomen is generally about normal in appearance. There may or may not be constipation. The urine seems the most distinctive feature, being loaded with amorphous urates and uric acid crystals entirely out of proportion to the fever and other phenomena. Closer study of the urine in all cases may reveal the true cause, possibly blood examinations assisting.

ILLUSTRATIVE CASES.

The following case histories illustrate the condition:

CASE 1.—Boy of 6, well nourished, whose father is subject to arteriosclerosis, and whose mother suffers with recurrent attacks of migraine. The patient had been subject to attacks generally of no longer intervals than eight months.

The prodromes of the attacks were generally malaise, headache, and disgust for food and soreness of the abdomen, with some rise of temperature. The attacks of vomiting were sudden, severe, occurring every half or 2 or 3 hours, and lasting for several days, till the child was completely exhausted. The fever continued throughout the attack. Convalescence was rapid. The urine was always loaded with excessive amorphous urates and uric acid crystals.

The treatment consisted of calomel 1/10 (plain, i. e., dry) on tongue, 1 every hour till ten doses; cocain ½ gr. in 24 hourse, given in ¼-hour intervals. Later, phosphate soda. He was restored to health.

CASE 2.—Pale, round-shouldered and of sickly appearance. Both parents were near the age of fifty at her birth and both are of marked neuropathic type. Her diet is always carefully regulated. Cold has precipitated an attack.

There has never been a history of indigestion or constipation, no acid eructations, or foul breath, or coated tongue, or bad taste in the mouth preceding an attack. Skin, conjunctiva and stools are about normal, and there is generally no gaseous distension of the bowels. The prodromes were heavy eyes, with dark rings beneath, no disposition to play, but rather to rest, lying down most of the day.

Vomiting began suddenly. The child insisted on the basin constantly at hand, saying every few minutes, "I am going to vomit," and retched violently. The blood was not examined. The urine was loaded with uric acid crystals and amorphous urates.

Cocain, at first in larger doses and gradually decreasing, controlled the attacks with calomel in tenths as before, dry on the tongue. This was followed by phosphate of soda, and later syr. hypo-phosp. comp. established convalescence.

CASE 3.—Girl, aged 9, of gouty family. Attack precipitated by grief over death of her mother. Mother's death caused by chronic interstitial nephritis, revealed at the autopsy, urinary findings being negative till fatal uremia. Child was of very affectionate temperament, pupils filling the eyes, a highly developed and easily irritated sympathetic nervous system.

Attacks began with nausea and slight vomiting for a time, and then attacks which were violent and persistent occurring almost every hour. Temperature ranged from 99 to 101. Vomited material consisted of frothy mucus and serum, very acid. The blood was not examined. The urine was loaded with excessive uric acid crystals and amorphous urates.

At the end of the third day the face was pinched, heavy black rings under the eyes, eyes half closed, body drained of fluids and condition one of prostration and collapse. The pulse was 160 and very weak, requiring digitalis and strych. hypodermically. The tongue was singularly clear and red. The abdomen was neither distended nor flattened, but about normal, although auscultation revealed an absence of peristalsis. There was present distressing thirst and hurried and irregular respiration, though hurried respiration, particularly at the time of vomiting, should have little significance, owing to the proximity of the respiratory and the vomiting center.

The treatment consisted of high enemas of saline solution and a hypodermatic injection of morphin 1/18, and atropin 1/500. The duration of the acute attack was five days. The after-treatment was symptomatic, consisting of sedatives, eliminatives and tonics.

During convalescence itching skin and eczematous rash over the buttocks suggested a blood irritant of the uric acid series.

Thirteen weeks followed of irregular pulse and slightly elevated temperature—90 to 100—with no other explanation than a marked disturbance of metabolism.

This case seems to be properly classified as of the "cyclic vomiting" type, the causative factor in this instance being an emotion from an unusual cause.

DIFFERENTIATIONS FROM OTHER ATTACKS OF VOMITING.

A condition most likely to be confounded with these gastric neuroses is the more ordinary recurrent bilious vomiting.

The points of distinction are these:

IN BILIOUS VOMITING.	IN CYCLIC VOMITING.
1. History, improper feeding.	1. No such history; may occur with most careful diet, with no symptoms of indigestion.
2. Unloading the bowels relieves.	2. No such effect.
3. Tongue coated.	3. May be clean.
4. Breath heavy.	4. Breath late in attacks may have wine odor of acetone, but otherwise normal.
5. Abdomen bloated and distended.	5. Generally about normal.
6. Abdominal pain and colic.	6. As rule, none.
7. Abdominal peristalsis and with colic.	7. Auscultation of abdomen, especially later in the attack, reveals absence of peristalsis.
8. Stools often clayey.	8. Generally normal.

IN BILIOUS VOMITING.	IN CYCLIC VOMITING.
9. Ordinary febrile urine.	9. Urine scanty and loaded uric acid crystals and amorphous urates out of proportion to other symptoms.

In cyclic vomiting, in conclusion, the excessive thirst, cyclic character, severity and persistence of the vomiting are quite pathognomonic. A differentiation of other causes of vomiting requires an examination of all the organs.

1. Vomiting may be due to local disease, irritation of the walls of the stomach itself, as in cases of any irritation, as of medicine or of food in quantity or quality, overdistension with gas, congested mucous membrane, with irritating secretions, which cases reveal themselves by a study of the relation of vomiting to food and a study of the material vomited.

2. Vomiting may be due to intestinal causes of quite the same nature as above or to such other abdominal causes as obstruction, peritonitis, appendicitis, which soon present very distinct physical signs and symptoms of these conditions.

3. It may be, also, reflex from other disturbance, as of the cerebrospinal system or the special organs—from brain disease, from the pharynx, eye or ear, or almost any organ.

4. Vomiting may be central or toxic from an irritating state of the blood acting on the vomiting center, in the same manner as a hypodermatic of apomorphia.

This would include infectious diseases, which soon express themselves by well-known symptoms or rashes, and the vomiting is generally neither prolonged nor excessive, and very frequently consists of but one or two explosive effects.

Among other causes of central vomiting may be included the toxemia incident to kidney disease.

In the vomiting of children it is always wise to follow two rules—to examine carefully the throat, and not to be easily convinced that the cause is local—an irritated or diseased stomach. Very frequently it is not at all of gastric origin.

The stomach, organic brain disease and organic kidney disease may represent the most frequent causes.

G. R. Butler[9] says: "Vomiting is sometimes seen as the only marked symptom of an apparently slight nephritis. In such cases its onset is abrupt, its course intense and its outcome not infrequently fatal."

5. Simple or tuberculous meningitis may present greater difficulties, especially when we consider that vomiting may be rarely the only symptom of such a meningitis till a fatal issue by convulsions. The condition of the pupils, the eye ground, irregular pulse and respiration assist the differentiation.

In the periodical vomiting which occurs in cases of tabes dorsalis in adults, a possible history of syphilis, the symptoms of station and patellar reflex and ocular symptoms are so characteristic that they can not be confounded and are mentioned only because articles on "periodical vomiting" refer to such neuroses, which are in no way related to cases of periodical vomiting now considered.

Other attacks of periodical vomiting, with abdominal pain, in adults, have been described in literature, but have none of the marked features of these attacks. Still other conditions described as periodical attacks of vomiting in children are very plainly recurrent bilious attacks, in children careless of diet and hygiene, which have been described.

That the phenomena of cyclic vomiting is due to some toxic blood state seems certain, the exact nature of the toxin remaining in obscurity. It may be allied to the unknown toxin of uremia. It is probably of the xanthin series, one of the uric acid group. The attacks resemble the so-called "uric acid storms" described so graphically by Haig, in that the extremities are cold, glandular secretions decreased and scanty urine and large excretion of substances regarded as uric acid.

The attacks differ in the fact that there is no headache or mental depression, and in the character of the pulse, which is not usually of high tension, but weak and irritable like the pulse of toxin poisoning. It is a pulse which can in no way be explained by the tension caused by impeded capillary circulation, which a colloid state of uric acid may occasion. The symptoms are not so much of uricacidemia and the clogging of capillaries as of some toxin possibly of the uric acid series acting directly on the vomiting center.

The impressibility of certain nerve centers, and the difference of susceptibility of particular nerve centers in particular individuals help to explain the phenomena. It is well known that toxins of the alloxuric group irritate particularly nerve centers, and that uric acid products are particularly injurious to nerve tissues, and we may be warranted in the assumption that some of these chief products of waste metabolism irritate the vomiting center in these gastric neuroses, though we do not know the steps of the biochemic process or the exact toxin. In all three cases there is a neurotic or gouty, or a neurotic and gouty family history.

In all three cases the presence of amorphous urates and uric acid crystals in excessive proportion to the febrile disturbance point to a toxin of the uric acid series. In each instance the alimentary tract and accessory glands seemed fairly normal and the autointoxication seems not of intestinal origin, but cellular, with perhaps faulty kidneys.

When we consider how little we know of the toxin of uremia—a condition more pronounced, more serious and more frequently at hand for study—we may be less chagrined at our lack of knowledge of the toxin in this gastric neurosis.

TREATMENT.

The treatment is sedative and eliminative. The indications are: First, to lessen the irritability of the vomiting center; and second, to eliminate. The first has been attempted by bromids and chloral by the bowel, which is not satisfactory. Nothing is so effective as hypodermatics of morphin and atropin in severe cases. In less severe cases cocain and Fowler's solution lessen irritability both of the vomiting center and the peripheral nerve endings in the stomach wall.

Elimination is best accomplished by calomel, dry on the tongue in small and frequent doses, in conjunction with high saline enemas.

Gavage has effected good results in young children. No other diet than some of the liquid peptonoids in form should be attempted for several days. In the interval there is indicated abundant fresh air and careful skin activity, exercise short of fatigue, an avoidance of nervous strain and child worry, with an antiuric-acid diet.

CONCLUSIONS.

In conclusion I wish to emphasize:

1. The importance of being watchful, on one's guard for the vomiting of this gastric neurosis, distinguishing it particularly from bilious vomiting and the vomiting of kidney disease and reflex vomiting, as of brain disease.

2. In children of gouty and neurotic history the three cases reported point to a toxin allied to the uric acid series as the possible blood irritant causing the vomiting.

3. The importance in severe cases of hypodermic injection of morphia and atropia in conjunction with elimination, by high saline enema; by gavage; and in extreme cases, hypodermoclysis and even intravenous injections of saline solutions.

Special Article.

THE TYPHOID EPIDEMIC AT ITHACA.

(By Our Special Commissioner.)

II.

THE DIVISIONS OF ITHACA IN RELATION TO TYPHOID INCIDENCE.

Very early in the history of the outbreak it was suspected that the public water supply was in some way implicated. With respect to the sources of the water used for domestic purposes the town may be conveniently divided into five different districts: 1, Receiving water exclusively from Six Mile Creek;[1] 2, receiving a mixture of water from Six Mile Creek and Buttermilk Creek in the proportion of 1:1; 3, receiving mixed water from Six Mile and Buttermilk creeks with an excess of the former in the proportion of about 3:1 or 4:1; 4, receiving water from Fall Creek; 5, dependent on wells, springs or sources outside of the regularly pumped supply.

The distribution of the cases of typhoid fever in the town at once drew attention to the significant incidence of the infection. The main city water supply is derived in part from Six Mile Creek alone, and in part from mixture of this water with that of Buttermilk Creek. The water from these sources (Districts 1 to 3) is furnished by the Ithaca Water Company, a private corporation. The Fall Creek source, which is controlled and managed by the university authorities, supplies the university buildings, some fifty-two houses on or near the campus, including six fraternity houses and about seventeen houses at Cornell Heights to the west of Fall Creek. This section of the town has remained exempt from typhoid fever, except in the cases of a few individuals, who resided on the campus but boarded elsewhere, and one student in Sage College, who is known to have drunk water in other parts of the city. With the one exception noted, the women students of Sage College, numbering over 200, have not been affected. The same is true of the students in the several fraternity houses that are supplied with Fall Creek water. The larger part of the town, however, especially that furnished with water directly from Six Mile Creek, has suffered severely.

It appears from the meager facts that could be learned concerning the distribution of cases within the infected area, that the district receiving exclusively Six Mile Creek water was much more severely affected than the rest of the town. This section, the East Hill district (1), which is thickly dotted with student boarding houses, has borne the brunt of the epidemic. In the district supplied with the mixed water from Six Mile and Buttermilk creeks, the proportion of cases appears to be smaller than on East Hill. In the outlying parts of the town, supplied with well water, the number of cases is said to be relatively small, although it is extraordinarily difficult to obtain precise information on this and all other points that require the consulting of accurate records. I have also found it impossible to obtain definite information concerning the distribution of population within the specified areas. The population supplied from Fall Creek numbers probably at least six hundred; and that supplied with mixed water from Buttermilk and Six Mile creeks is considerably larger than that supplied from Six Mile Creek alone; but beyond these facts there is little to assist the investigator in determining the proportion of cases to population. In view of the compact character of the town, and the opportunities for using infected water throughout most of its territory, it is certainly rather surprising that there have not been more cases of incidental infection among the population supplied by Fall Creek. If the disease had been distributed evenly over the city in proportion to the population this district should have had at least 30 indigenous cases, whereas it is not known to have had one. The fact that the section receiving Six Mile Creek water but no water from Buttermilk Creek (1) has been

1. First pumped to a small reservoir containing less than a day's supply.

seriously attacked, and that the section supplied with the mixed water from these two sources has also suffered, points unmistakably to Six Mile Creek as the source of infection, although the possibility that Buttermilk Creek was simultaneously infected can not be excluded.

As regards the especially heavy incidence of the disease on District 1 there are several ways in which this might be explained. In the first place, the fact that in this district the Six Mile Creek water alone is used would seem to indicate both a more direct and a quantitatively greater infection. A second factor that has undoubtedly played a part is the age distribution of the population in this district. The large number of university students dwelling in the East Hill boarding houses constitutes an

age group possessed of maximum susceptibility to typhoid fever. It is well known that the greatest susceptibility to this disease is between the ages of 15 and 25, and that consequently a population of college students presents a mass of material of peculiarly inflammable nature. A third factor that may possibly be important is that the student population is not composed of permanent residents and hence had been relatively untried by typhoid infection. It is probable that many of the inhabitants of Ithaca, living in the lower town, had at one time or another suffered from mild or unrecognized cases of typhoid fever, the so-called "Ithaca fever," or "typhoidette," to use the term of some of the French epidemiologists (Lorain). There is a certain amount of evidence that exceedingly mild infections, often not recognized as specific, confer immunity to subsequent attacks of typhoid fever. On this ground, it would not be at all remarkable if the disease had raged more severely in the virgin soil of the student boarding houses than among the previously exposed and presumably somewhat seasoned inhabitants of Ithaca. Probably all of the factors mentioned have contributed somewhat to the extraordinary prevalence of the disease among the student population on East Hill.

CHARACTER OF THE WATER SHEDS.

The conditions surrounding the several sources of water supply are particularly significant. Six Mile Creek, which affords the major part of the town's supply, has a watershed with an area of about 48 square miles.

The watershed is slightly more than ten miles in length and is very narrow; the numerous small and rapid feeders of the main stream traverse for the most part short distances. The stream is not a large one; the average daily flow during January and February, 1903, is estimated at five to six million gallons, and during a large part of the year it is much less than this. Without a storage system, it does not alone suffice for the town supply (two to three million gallons daily). The population on this watershed may be roughly estimated at 2,300-2,500. Most of these inhabitants live in scattered farm houses, although two small village communities, Brookton and Slaterville, the latter a summer "health resort" with several small hotels, are within this area. Observation of the conditions prevailing on this water-

shed at the time of the writer's visit showed that many of the houses are situated on the very border of Six Mile Creek or its tributaries, and that, in many instances, there is abundant opportunity for fresh drainage from manure piles, pig pens and outhouses to pass directly into the stream. The accompanying illustrations[2] represent views taken along the banks of Six Mile Creek in the village of Brookton, four miles above the point at which the Ithaca supply is pumped. In certain places the slope of the ground is such that the drainage from outhouses and privies can pass freely into the stream. The current in Six Mile Creek and its tributaries is swift, and at those seasons of the year when the streams are full, it

is possible for drainage from almost any part of the watershed to arrive at the water intake within three or four hours after entering the stream.

Buttermilk Creek, which at present furnishes part of the public supply, was not visited by the writer, but is said to have a watershed of very similar character to that of Six Mile Creek. It is stated to be in somewhat better condition than that of Six Mile Creek, principally because the stream is not so long. A report on Buttermilk Creek, made Feb. 16, 1903, by official inspectors of the local board of health, contains the following suggestive items among many others of a similar character:

The next residence on the right bank of the stream is that of Mr. E., standing on a tributary. The closet is within ten feet of the tributary, and the hen house and hog pen stand about twenty feet from the tributary, with the slope toward the tributary. . . .

At the residence of J. McF. the closet is within fifteen feet of the stream, with the bank sloping steeply into the water; at this place there are five cases of scarlet fever, two of whom are recovering. The barn and pigsty stand on the bank of a short tributary to the stream, and drain directly into the main stream. . . .

At the residence of J. G. the closet is directly on the bank of the stream, with no vault underneath.

The watershed of Fall Creek, from which the water supply of the university campus and some closely con-

tiguous territory is derived, is, if anything, in a less satisfactory condition than that of Six Mile Creek. In proportion to the size of the watershed and length of the stream, the amount of pollution is greater than in either of the other sources. About one mile above the water intake is located the small hamlet of Forest Home, where the opportunities for direct and rapid drainage into the stream are even more conspicuous than at Brookton. If an unwatched or improperly-cared-for case of typhoid fever had developed at Forest Home, infectious material might conceivably have passed into the university supply with great promptitude. No greater safeguards appear to have been thrown around the Fall Creek supply than around that of Six Mile Creek. In fact the general surroundings of Fall Creek are apparently of a much more dangerous character.

2. These views were taken last week especially for THE JOURNAL and to accompany this report. They describe more graphically than words the true conditions. Other photographs were taken but the ones here reproduced are believed to be amply sufficient.

QUALITY OF THE WATER.

It has long been a matter of common knowledge in Ithaca that the town water supply was not above criticism. Many citizens have not used the public supply for years for drinking purposes. The use of boiled water or of spring or artesian well water has been general; such measures of protection have been often resorted to by the advice or on the warning of the Ithaca physicians, many of whom appear to have been alive to the situation. The writer has been told that the use of the raw water for drinking has been known in certain families to bring on attacks of "bowel complaint." These attacks ceased if a different water were used, only to reappear when the drinking of raw water was resumed. More than this,

analyses of the town supply have shown on several occasions that the water contained objectionable or suspicious constituents. A report was made to the Ithaca board of health, March 11, 1902, by Professor Chamot of Cornell University, in which, after a detailed report on the results of examination of the water, the water was pronounced "unfit for drinking purposes." It is stated that analyses of the Fall Creek water have in general shown somewhat greater pollution than the other sources.

Long before the present outbreak, therefore, the facts were at hand concerning (1) the excessive prevalence of typhoid fever in the town, (2) the character of the several watersheds draining into the streams which were the source of the town's supply, and (3) the quality of the water itself and the effect of its use on the health of citizens.

(To be continued.)

Careless Prescribing.—I have been astonished at the original prescriptions of men who, in all branches of their profession except therapeutics, were quite capable. They seemed to have no knowledge of the incompatibility of drugs. A few instances may suffice to illustrate this. Cocain and borax are often ordered in the same mixture, with the result of forming an insoluble precipitate of cocain borate. Ammonium carbonate is frequently ordered by physicians in the same cough mixture with syrup of squills, which contains acetic acid, with the result that a chemical reaction takes place liberating carbon dioxid, and the gas given off startles the patient by forcibly expelling the cork or even bursting the bottle. An acid and an alkali should only be mixed when a new product is desired. How frequently iron is ordered mixed with substances containing tannic acid, with the result of forming iron tannate or ink. —H. R. Purdy, before the N. Y. State Med. Assn.—"Amer. Druggist."

That Decreasing Birth Rate.—Statistics continue to appear on this subject in the press of the country. An editorial in THE JOURNAL, Feb. 21, 1903, page 521, expressed doubt as to the fact of an actually decreased birth rate Apropos are the statistics presented by the "Northwestern Christian Advocate," which seem decidedly at variance with some previously referred to in our columns. The "Advocate" says that the analysis of the statistics on births compiled by the twelfth census does not bear out the contention that the birth-rate in the United States is decreasing. At least the figures, based on what the compilers of part 1 of the vital statistics say are imperfect data, indicate that there was a slight increase in the birth-rate for the decennial period of 1890-1900 over that of 1880-1890. Not the least interesting feature is that the greatest increase occurred in the northeastern or New England group of states, which includes New York (compare with THE JOURNAL, March 14, page 722). In this division the increase was 1.7 per 1,000. An analysis of these figures, including the average annual excess of births over deaths for the period from 1890 to 1900, shows the following results.

	Birth-rate 1890.	Excess births over deaths.	Birth-rate 1900.
United States	26.9	17.7	27.2
Northeastern division	22.1	11.5	23.8
Central and northern division	26.8	18.4	25.9
Southern division	30.1	19.8	31.5
Western division	22.9	18.7	22.8

The Diabetic Flour Swindle.—According to a Massachusetts State Board of Health report, of thirteen samples of diabetic flour, or flour prepared for the use of diabetics and purporting to be free from starch, only three samples, the product of one manufacturer, were found to be free from starch; the other ten, or nearly 80 per cent. of the samples collected, were found not only to contain starch, but that in large quantities, seven being found with 60 per cent. or more of starch. These were in reality but little better than whole wheat flour, and were sold at prices varying from eleven to fifty cents per pound. There are probably few of the better informed of general physicians who would not say, "All the better for the patient, so far as his health is concerned," because bread that does not contain starch doubtless injures him more than the best-made, well-baked "crusty" wheat bread. There seems to be a deal of indefiniteness and a vast deal of difference of opinion among physicians as to these questions of bread and diet for diabetic patients. These differences do not show themselves so much in the text-books, where there is general uniformity of advice. But when it comes to getting his bread the poor diabetic finds that the physician knows little or nothing as to the chemic and digestive qualities of the breads he can buy. The matter is left without oversight to the bakers and commercial agents, precisely where it should not be left, and much to the perplexity of the patient. No wonder that the diabetic's health fails when he tries to digest some of the "bread" he is advised to get! After trying it he can but think, if he does not know that his disease is a modern one, that the origin of the scriptural injunction against giving a stone when bread is asked for arose from the experience of his poor ancient brethren in trying to live while conforming to the scientific diet-list of those days.—"American Medicine."

SATURDAY, MARCH 28, 1903.

THE RESPONSIBILITY AT ITHACA.

There was a time when the epidemic of typhoid fever at Ithaca would have been looked on as a visitation of God; at the present time it must be recognized as a failure on the part of some persons to do their duty. Sometimes there may be an excuse for not recognizing signs of danger; but not in this instance, for they were too apparent; even the pictures obtained by our commissioner and presented in this issue prove this. The situation as depicted in his report is of no uncertain character.

The Ithaca Water Company, which owns and controls the water pipes, pumping stations and their connections, and presumably also certain portions of the drainage area, can hardly be absolved from a share in the responsibility for the disaster. The condition of the watershed furnishing the main supply appears to have been so patently dangerous that the most superficial observation could detect the mischievous possibilities that flaunted themselves along the banks of the stream. A private corporation, although primarily organized, it is to be presumed, for purposes of private or corporate gain, nevertheless incurs certain responsibilities which can not be lightly disregarded in undertaking to distribute a commodity so indispensable as drinking water. It is possible that even if the banks of Six Mile Creek had been carefuly patrolled, and if all nuisances along its banks had been abated just as far as was practicable, the epidemic might still have occurred. The fact, however, that such obvious and elementary precautions appear to have been largely, if not altogether, neglected, throws a heavy weight of responsibility on the water company.

The city authorities of Ithaca must likewise not be surprised if they receive from the world at large their share of the blame for the outbreak. Although spasmodic efforts seem to have been made from time to time to cope with the water situation and plan for its betterment, there appears to have been no concerted and definite plan of action which could result in efficient treatment of the problem. There is unfortunately only too much reason to believe that many American municipalities are in a position very similar to that of Ithaca in respect to an unguarded supply of surface water, and are allowing themselves to drift along from year to year in the easy assurance that nothing serious will happen. In most cases nothing does happen other than an excessive tribute paid each year in the deaths of young men and young women from typhoid fever. Occasionally, however, some unusual occurrence, like the one at Ithaca, will cause an amount of illness and death so great as to focus the eyes of the whole country for a time on the afflicted community. It would perhaps be unjust to condemn too severely the negligence or indifference which has the supreme misfortune to be punished by a particularly violent outburst of disease, so long as it is known that a very large number of municipalities are taking similar risks, and, safe in the happy doctrine of chances, are likely to escape similar retribution.

In turning to the possible responsibility of the authorities of Cornell University, the matter assumes a somewhat serious aspect. The influence possessed by the University in the councils of the town, its financial and moral prestige and the fact that it possessed, or might easily have secured, expert evidence as to the character of the town water supply, are all factors that can not be ignored in forming a judgment. Not only was it notorious that the town water supply was bad, but it was known that typhoid fever had for some years prevailed excessively; and the dangers to a community largely composed of college students, from the deplorable situation portrayed by our commissioner, ought to have been clearly foreseen. The university housed within its own walls many men who would have informed it without ambiguity or hesitation as to the existing situation and the catastrophe which might some day not unreasonably be expected if nothing were done.

It has been urged in defense that Cornell University incurred no more responsibility by allowing such conditions to exist than Columbia University or the University of Pennsylvania assumes for the water supply of New York or Philadelphia. The cases, however, are by no means parallel. Apart from the fact that public opinion generally will hold that the universities named would be unquestionably to a large extent morally liable for an outbreak of typhoid fever among their students, unless the authorities do all in their power to provide a pure water supply, it can not be said that the responsibility of a university in a great city is at all in the same category with the responsibility of a university in a small town, which it can largely influence or even, if necessary, dominate. The apparent neglect by the Cornell authorities of their responsibilities is further shown by the facts given regarding the university's own water supply, which, although not incriminated in the present outbreak, does not appear to have been surrounded by any substantial protection. We are reluctantly forced to believe that the Ithaca epidemic will always be looked on as an instance of oversight and neglect on the part of those in control of a great educational institution. Instances of amazing indifference and ignorance on the part of private water companies and municipal officials are not as uncommon as they should be, but that the

authorities of a great university should fail to realize their responsibilities in such an important matter may well give rise to more than passing wonderment.

THE SANITARY PROBLEMS OF THE PANAMA CANAL.

There is no great enterprise which tends to revolutionize the commercial channels of the world that has not its important sanitary aspects. Just at this time the Panama Canal seems a reasonable certainty in the not very distant future and the water route to Eastern Asia will be largely diverted from its present channels. The possibilities of this fact as regards health and sanitary matters are really serious and important.

In a discussion at the London Epidemiological Society, February 25, Dr. Patrick Manson took up this subject, calling attention to the diffusion of disease by insects, especially the mosquito as the intermediary host of the specific hematozoa, with special reference to the question of yellow fever as it concerns the Panama Canal. At the present time yellow fever is a disease confined particularly to the east coast of America and a part of the west coast of Africa, occasionally, however, passing across the isthmus routes to the Pacific ports of Central America. Thus far the Orient has escaped. With the building of the canal there will be many thousands of oriental laborers employed. They will come by the shiploads from Japan and China and return with whatever infections and diseases they have acquired in their more or less prolonged residence along the unsanitary isthmus. Yellow fever is a disease which, while not constant or indigenous on the isthmus, is yet comparatively frequent there on both sides, and its prophylaxis will be hardly less important than that of malaria, which in its pernicious form has there cost so many lives in the construction of transportation works, railroads, etc., in years past. The stegomyia is almost a universally distributed mosquito throughout the tropical and subtropical regions of the earth; the means for the diffusibility of the disease, therefore, are supplied. This mosquito can live as long as 75 days, and a voyage of eight or ten weeks across the tropical Pacific would be no surety against its transmission. There have been cases reported where ships have carried yellow fever without having any cases of it aboard. The only security is in thorough fumigation of vessels and destruction of any mosquitoes that may be secreted in their recesses. Dr. Manson suggests an international commission of all the civilized powers to act on this matter. Inasmuch as this would imply a certain amount of police power, it is doubtful whether the proposition is a thoroughly digested one. But certainly something should be done to prevent the spreading of this pest into regions where it has not before existed. He also suggests a clearing and absolute drainage of the country within half a mile of the canal on each side as a necessary item of prophylaxis. It is doubtful whether all this could be done at once, but much can be done, and with wideawake port sanitary authorities it does not seem that transmission of the disease can not be prevented even without the complete and most thorough methods he suggests.

There is still another point to be considered in connection with the rapid and frequent transit between Asia and tropical America which the canal insures. There is an equal chance for the introduction of Asiatic pests and scourges to this continent. The plague is almost endemic in some of the eastern countries, and cholera is still more so. We know what plague can do on the west coast of Mexico from the little epidemic that occurred at Mazatlan and one or two other places. Any wholesale introduction of this disease, which is just as possible as the introduction of yellow fever into Asia, might produce consequences which would be worse than anything we have yet seen or imagined.

The building of the canal itself involves sanitary problems of a serious character. In some respects the Nicaragua route would seem to have been a less pestilential one, though its inconveniences in other respects seem to have decided the matter against it. The west coast of Central America at least is comparatively healthy. On the east coast the severer forms of malaria are more or less prevalent. The subject is a timely one for us to consider.

It is not out of place also to reiterate what we have said before in regard to having a well-qualified medical man among the commissioners, who shall have full and complete charge of all sanitary arrangements and work. There is no doubt that there will be a physician in charge of this branch, but unless special effort be made to have such full powers allowed him, this position will be a vexatious one, and his views will be carried out or not as it pleases those who may be above him. Now is the time for action, as those men who are to have charge of the work will soon be appointed by President Roosevelt.

CYTOTOXINS AND THE PATHOLOGY OF PREGNANCY.

Among the most interesting of the researches on cell toxins is that in which the exciting substance is placental tissue. It is of special interest, first, because there is a possibility that some features of the pathology of pregnancy may be explained by the results obtained, and, second, because the practical use of the serum so obtained seems nearer than is the case of many of the other cytotoxic serums. A reason for this hope lies in the fact that placental tissue is the tissue, par excellence, that can be obtained from human beings in fit condition for use in immunizing animals. With the exception of the blood the placenta is practically the only human substance available for this work. W. Liepmann[1] has already made a number of experiments showing that the serum of rabbits immunized with human placenta will produce a precipitate when added to clear human serum that has stood for a time in contact with placental tissue. As he was able to produce a similar precipitate with blood serum from the umbilical cord of infants, and also

1. Deutsche med. Wochenschr., 1903, xxix, No. 5.

with retroplacental blood serum, he concludes that certain constituents of the placenta enter the blood stream. The practical bearing of this lies in the possibility that here is discovered a new method for diagnosing pregnancy. It is well known that placental cells enter the blood of the mother during pregnancy, for they have been found as emboli in the lungs, kidney and elsewhere. Liepmann promises to investigate this subject further.

In connection with the pathology of pregnancy we have the old theory that eclampsia is due to products of placental disintegration, either soluble substances or the cellular emboli above mentioned. Some of the earlier investigators of placental toxins stated that they found injections of human placenta toxic to animals, but Liepmann, who carefully excluded bacteria, did not get any such results. Albuminuria had been noticed in many of the animals and considered of significance in relation to eclampsia, but he considers this a simple physiologic albuminuria, such as is found when foreign proteids are introduced in large amounts into the circulation. However, if there is any basis for the placental origin of eclampsia, the use of serum of animals immunized with placental tissue may prove of therapeutic benefit. Hence, a study of the effect of placental serum on pregnant animals will be of interest, but let us hope that a new abortifacient has not been discovered.

Ascoli[2] has studied particularly the relation of cytotoxins to eclampsia. Rabbits were immunized with guinea-pig placenta, and their serum, although not toxic to pregnant guinea-pigs when injected subcutaneously or into the veins, caused symptoms that seemed to him much like those of eclampsia when injected under the dura. Controls showed that normal serum had no such effect, and rabbits did not suffer any symptoms from such injections. He suggests that the placental cells that are swept into the circulation during pregnancy may cause the production of cytotoxins leading to eclampsia. This reasoning from animal experiment to human disease is open to the objection so often advanced in cytotoxic work, that the serum used in the guinea-pig was from the rabbit, and was shown to have no effect on rabbits. In the case of eclampsia there is no question of foreign serums, and there is a wide gap between "autocytotoxins" and "heterocytotoxins." Of course, we must bear in mind that in eclampsia it is not at all impossible that the fetus plays some part.

To us the most suggestive feature of all this work has yet to be pointed out; that is, the use of this particular serum in the treatment of tumors. The proposition that tumors might be influenced by cytotoxic serum was the first outcome of cytotoxic work, but the development of this very important application has been prevented by the impossibility of procuring sufficient tumor tissue with which to immunize the animals that should furnish the serum. With the placenta it is different, for, first, this tissue can be readily obtained, and secondly, tumors of placental tissue differ from ordinary tumors in resembling more the parasite as it attacks the host. Syncytioma malignum is fortunately rare, but extremely malignant. It is often diagnosed from scrapings or operation before great inroads have been made. The tumor develops from a tissue that is practically foreign to the host, and in this way resembles a parasite. The parent tissue is not of vital importance; if we could prepare a serum for hypernephroma, for example, we should fear its attacking the normal adrenal structure as well as the tumor, with disastrous results, but there could be no such difficulty in the case of the placenta. For these reasons it seems that placental cytotoxins offer a particularly practical field for study, and that syncytioma may be a good point at which to attack the problem of serum therapy of cancer.

2. Centralblatt f. Gynækol., 1902, xxvii, No. 49.

MEDICAL JOURNALS AND WEEKLY EDITIONS.

The *Allg. Med. Ct.-Ztg.* of Berlin is now in its seventy-first year, and has been published heretofore two or three times a week. It now announces that a single weekly edition will be issued henceforth. The *Archives Gén. de Médecine* has changed from a monthly to a weekly with the new year, the eightieth of its existence. The Italian *Riforma Medica* has long proudly boasted that it was the only medical daily published in the world. It, too, has fallen into line with the weeklies, and the nineteenth volume, commencing with the current year, brings it as an enlarged weekly journal. The *Bulletin Médical* of Paris is about the only one of our exchanges that still clings to two editions a week. The *Gazette Hebdomadaire,* which belied its title by publishing two numbers a week, ceased publication with the close of 1902, its forty-ninth year. One of its features will be much missed unless inaugurated in some other journal. We refer to the lists with abstracts which it published of the medical theses presented at the French universities. The Paris *Gazette des Hopitaux* has three editions a week, and also the Italian *Gazzetta degli Ospedali,* but in the latter the original communications are restricted to the Sunday issue, which appears with a colored cover. The journal is thus practically a weekly with two supplements for abstracts. One of the changes brought by 1903 in our exchanges is that the letter C is being tabooed to a certain extent in Germany. Our familiar friends, the weekly *Centralblatts,* are *Zentralblatts* now, *Medicin* is *Medizin,* and so on. This seems to be merely another evidence of the tendency displayed by the Germans to refrain from using the terms which are current in science the world over and which are gradually developing an international scientific language. The Germans are serene in their consciousness that no scientist can work without a knowledge of what is being done in Germany in his line, and consequently he is obliged to put up with whatever home terms they may choose to use. They care nothing for the expense of dictionaries and waste of time which they impose on the scientist with the word *Wurmfortsatz,* for example, where all the rest of the world says *appendix, angeboren* instead of *congenital,* or *Speiseroehre* for *esophagus,* etc. In fact, we suspect they are inclined to chuckle over the

difficulties they place in the path of the scientist of another nationality. It serves him right for not having been born a German.

CÆLUM, NON ANIMUM MUTAT.

Change of locality seems to have little effect on the ill luck of a noted biologist recently transferred from Chicago to California. He is, it is said, greatly troubled by the fact that his utterances are still picked up by reporters in the most sensational way from time to time. In fact, there is a very short interval between them. One day it is announced in the newspapers that the actual secret of life has been found in cyanid of potash, again it is calcium salts that have an importance which has never been before attributed to them in the vital processes. The last announcement is that the revelation of the nature of life itself is probably within our reach. All that we have to do to understand it completely—and he seems to think this will be done—is "to control it unequivocally by physical and chemical means, or to repeat it in all detail on inanimate matter." This is a large contract. There is a sort of wisdom which consists in appreciating our limitations. A wisdom that is lacked by the antivitalist who can not willingly believe that anything mysterious exists or that it is beyond his intellect. Our modern would-be Prometheus says:

> We can not allow, however, that there is any obstacle to our complete control, and, in consequence, to our knowledge, of life phenomena. Every one, I believe, who recognizes the control of life phenomena to be the greatest problem of scientific investigation will come to the same conclusion. Authors who have come to the opposite pessimistic view have placed too great faith in some hypothesis or have fallen victims to a poor or wrong interpretation of the facts. It is self-evident that the pessimistic view can only hinder, but never further, the progress of science.

What hindrance is it to research for one to believe that thus far nothing has been done to actually or satisfactorily solve the mystery of life and that it is possible that it is beyond our reach? There are such things as infinity and eternity which have to be considered—absolute ideas that can not be dispensed with, and yet absolutely ungraspable by the human intellect. The phenomena of life itself seem in some respects to be among those of which we may be unable to fully obtain the secret. It would be more discouraging to think that we can solve all questions and research thus come to an end, than to believe that there is always to be something ahead of us. The so-called optimism that claims that the whole universe is to be included within the horizon of our senses seems to us little less than irrational, and what is here called pessimism seems altogether more becoming to our limited intellect. It is not pessimism, however, to believe that with our better developed intellects of one thousand years from now there will be as much prospect of future discovery as at the present time.

HYDROPHOBIA.

The recent death of the eight-year-old child of a prominent physician in New York ought to be sufficient to convince the most rabid oppositionist of the existence of the disease that it is really a formidable entity. The case was seen by some of the best specialists in New York, the diagnosis confirmed and the history of the case thoroughly reviewed. Of course, those who believe that dogs should suffer no inconvenience though human beings may die, as we see in the tone of the antivivisectionist publications, would be satisfied with nothing, but at least such physicians as have criticised the views of those who believed in hydrophobia ought to accept this evidence. The important thing about it, however, is not the mere question of the existence of hydrophobia, but the increasing prevalence of the disorder. There seems good reason to believe that there are more cases in late years than there formerly were. This is not difficult to explain when we remember that hardly anything has been done to check it; that mad dogs have existed from year to year, biting others; that restrictive measures like muzzling are in most cases neglected, and that the public has been criminally indifferent on the subject. In England up to a year or two ago the dog-muzzling law was enforced, and as a consequence hydrophobia is almost unknown in that country. We have a larger territory to guard, and it would be more difficult to keep the disease out of any one single section than it is to keep it out of an island where all commercial routes are by water, through well-known channels, custom houses, ports, etc. But still much can be done, not only in our cities, but also in the rural districts, if the popular notions about dogs were only somewhat modified. They are not the friends of humanity in the long run that they are said to be, and there is a vastly greater number of them in existence than is justified by any requirement or good policy. The poorer the family the more dogs, as a rule, in the rural districts, and the greater the risk when rabies occurs among them. In the far north where dogs are useful domestic animals rabies or something so similar that it is practically identical, decimates the packs annually, and is recognized by the natives and duly feared. There are no records, of course, among the Eskimos, of any human beings having suffered there, but there is little doubt that such has been the case. In some countries, like Australia, it seems never to have been introduced. There is ample proof that it is a preventable disease and it would be well to bear in mind this fact, and insist on greater care in enforcing the taxing and muzzling of dogs, even to the extent of appreciably diminishing their number. The loss of a single human life from hydrophobia is of more importance than the death of thousands of canine quadrupeds.

Medical News.

CALIFORNIA.

Personal.—Dr. Elliott H. Woolsey, Oakland, and wife sailed on a trip to Japan, China and the Philippine Islands, March 11. He expects to return in about six months.

Quarantine Lifted.—As no new cases of scarlet fever had been reported at Marysville for ten days, the regulations prohibiting public gatherings were suspended March 11, and the schools reopened March 16.

Hospital Election.—The Sequoia Hospital Association (Eureka) has elected the following officers: President, Dr. Jay L. McLaren; vice-president, Dr. William H. Wallace; treasurer, Dr. Rae Felt, and secretary, Dr. Charles C. Falk.

Savage Amendment Fails.—The senate, by a vote of 18 to 17, defeated Senator Savage's bill to amend the medical practice act by taking the power of appointing the State Board of Medical Examiners from the state medical societies and vesting it in the governor.

"Divine Healer" Arrested.—John Miller, calling himself "Dr. Miller, the Divine Healer," of Bakersfield, was arrested, March 4, charged with practicing medicine without a license and released under a bond of $50. He failed to appear March 6, his bond was forfeited and he was arrested and placed in jail.

ILLINOIS.

Beverly Farm Improvements.—Dr. William H. C. Smith, superintendent of the Beverly Farm Home and School for Nervous and Backward Children at Godfrey, is building a log cabin as a rendezvous for his boys, and also a schoolhouse, gymnasium and dormitory for the children under ten, to cost about $4,000.

Keeley Company Sued.—The Memphis Keeley Institute has brought suit against the Leslie E. Keeley Company of Dwight, for $100,000 for violation of contract. The plaintiffs paid $50,000 for the sole and exclusive use of the so-called chlorid gold treatment in Tennessee, and was to be furnished the medicine at a discount of 40 per cent. The plaintiffs also allege that the defendant sold double chlorid of gold remedies, which were different in their constituent and component parts from chlorid of gold remedies. The drugs "are deleterious and dangerous to health of the patient," says the bill, "bringing about great physical weakness, dilation of the eyes, dryness of the throat, full feeling in the head, often confusion of ideas, impairment of memory and weakness of mental capacity."

Chicago.

Lorenz's Assistant to Locate.—Dr. Friedreich Mueller, former assistant to Dr. Lorenz, has returned to Chicago, and the daily press announces that he will locate permanently here and practice his specialty of orthopedic surgery.

The Worst Over.—Although eleven cases of smallpox were discovered during the week, the belief is expressed by the chief medical inspector, Dr. Heman Spalding, that the "worst is over for this season." The usual features of never vaccinated, disproportionate excess of colored and of children under the school age still obtain. Of the 24 fatal cases during the year, 19 were of children under 6 years of age, while there has not been a single fatal case for years among the vaccinated school population.

The Dead.—During the week ended March 31, 612 deaths were reported, 19 less than for the previous week and 75 more than for the corresponding week of 1902. The 19 fewer deaths are equivalent to a reduction of not quite 3 per cent (2.98) from the rate of the previous week, but the total, 612, represents an excess of 10 per cent. over that of the corresponding week of last year. Pneumonia heads the death-list with 133, and tuberculosis comes next with 62. Heart disease caused 44 deaths; Bright's disease, 34; typhoid fever, 13; influenza, 13, and violence, 40.

Improvement in Public Health.—Indications from the laboratory and reports from physicians and hospitals point to a general improvement of the public health. Influenza is still rampant and is largely responsible for the higher death rate of the winter. It continues to be reported as a fatal complication of consumption, Bright's disease, pneumonia and heart disease among the aged and of the acute contagious diseases of childhood. Measles and whooping cough are still very prevalent and of unusual malignancy, while diphtheria and scarlet fever are decreasing.

Increase in Pulmonary Disease Mortality.—In the report of the Department of Health for the week ended March 21, the following reference is made to the increase in mortality from pneumonia and tuberculosis:

> March 21, there had been registered a total of 679 deaths from consumption and of 1,455 deaths from pneumonia since the first of the year. During the corresponding period of 1902 the respective totals were 619 consumption and 1,095 pneumonia.
>
> These figures show increases of 9.6 per cent. of consumption mortality and 32.8 per cent. of pneumonia mortality. And they also show that the excess of pneumonia mortality over consumption mortality—which was 76 per cent. in 1902—has risen to 114 per cent. this year.

INDIANA.

Alexander Again Indicted.—On March 13 the grand jury returned a new indictment against Dr. Joseph Alexander, at whose previous trial on the charge of grave-robbing, the jury disagreed.

School Children Must Be Vaccinated.—The decision of the Appellate Court, March 18, upholding the power of school boards to compel the vaccination of children, will be followed by rigid enforcement of vaccination throughout the state. Dr. Hurty, secretary of the State Board of Health, has detailed his reasons for the belief that the state will be scourged with smallpox unless radical measures are enforced.

The State Morbidity.—The regular monthly reports to the State Board of Health show that influenza prevailed very extensively in February. The type was severe and seemed most frequently to leave an impression on the nervous system. Smallpox was very slightly less prevalent than in the preceding month, there being 889 cases in 59 counties. Bronchitis and tonsillitis were widely spread, and diphtheria increased slightly.

License Revoked.—The State Board of Medical Examination and Registration has revoked the license of Daniel D. Weiser, Bourbon, who failed to appear and show cause why his license should not be revoked. Weiser had an old license, procured prior to the establishment of the present board, by displaying a diploma which he claimed was granted by a reputable college, when in fact it was bought from a diploma mill, and was not a result of study. He applied to the present board at the time of its establishment for a new license and was refused for these reasons. He then went to Michigan. He returned, recently, took the old license to the county clerk and received a new one.

Deaths in the State.—The total number of deaths was 2,677, an annual rate of 13.8 per 1,000. This is a decrease as compared with the same month of last year. Pneumonia caused 339 deaths; tuberculosis, 342; cancer, 92; influenza, 56; diphtheria, 53; smallpox, 50; and typhoid fever, 49. The city death rate was 17.3, which is 3.5 higher than the average rate for the whole state. Exactly the same rate existed in February, 1902. The country death rate was 11.9, which is 1.9 less than the state average, and 1.7 less than in the same month last year. Consumption prevailed more extensively in the cities than in the country, the rate being respectively 195.4 and 137.8 per 100,000. Pneumonia also prevailed more extensively in the cities, with rate of 236.4, and country 190.4. Of the smallpox deaths 43 occurred in the cities, 38 of which were in Indianapolis and 7 in the country. Of the 92 deaths from cancer 44 occurred in the cities and 48 in the country.

Laboratory Bill Vetoed.—The action of Governor Durbin, according to the newspapers, in vetoing the Ogborn state laboratory bill, is receiving severe criticism by members of the medical profession. Some charge, it is said, that personal matters influenced the action of the governor for there was no serious opposition to the bill from any quarter. The bill passed the house by a vote of 77 to 13 and the senate by a vote of 44 to 6. It had the endorsement of the Marion County Medical Society and the State Medical and the State Pharmaceutical Associations. The bill carried an annual appropriation of $10,000 for maintenance. The laboratory was to have been used to enforce the state's pure food law, which at present lies dead on the statute books, while the people of Indiana pay probably not less than $5,000,000 a year for adulterated foods. It was expected that the laboratory, which was to be conducted under the direction of the State Board of Health, would also be used in the early discovery of diphtheria, consumption and other similar diseases.

MARYLAND.

Baltimore.

Alumni Elect.—Mr. B. Howard Haman, LL.B., has been elected President of the General Alumni Association of the University of Maryland, and Dr. Eugene F. Cordell, secretary-treasurer.

Woman Gets High Mark.—At the recent examinations before the State Board of Medical Examiners, the highest honors were carried off for the second time by a graduate of the Woman's Medical College.

Left to Hospitals.—The will of the late Mrs. Lavinia E. Frey leaves $500 each to the Union Protestant Infirmary, the Nursery and Child's Hospital, and the Presbyterian Eye, Ear and Throat Charity Hospital.

Deaths of Last Week.—The number of deaths last week was lower than for several years past, being only 184, an annual mortality rate of 17.66 per 1,000, viz., for the white 14.87, and for the colored 32.97. Eight deaths were from grip, 28 from pneumonia, and 3 from measles.

Medical History.—At the Johns Hopkins Hospital Historical Club, Prof. Henry E. Shepherd delivered an address on "Medi-

cine in Shakespeare," and Dr. Julius Friedenwald brought out the fact that Dr. Philip Syng Physick of Philadelphia discovered and was the first to make use of the stomach tube. Dr. Thomas McCrae spoke on "George Cheyne—An Old London and Bath Physician (1671-1743.)"

The Book and Journal Club of the Medical and Chirurgical Faculty.—At the first meeting for the season, March 26, Dr. Alfred Stengel of Philadelphia, read a paper on "Some Old Instruments and Methods for Treatment of the Stomach. Gastric Sensations Interpreted as Live Animals in the Stomach." Dr. William Osler presented the library with 123 theses of American students at the University of Edinburgh between 1760 and 1810, and Dr. Henry B. Jacobs made a few remarks on "A Century of the Faculty of Medicine of Paris, 1794-1894."

MINNESOTA.

Personal.—Dr. Oscar A. Burton, Albert Lea, will leave in May for several months of study in Vienna.——Dr. Carl J. Ringnell, Minneapolis, has been reappointed a member of the State Board of Medical Examiners.

The Open Door.—A bill introduced in the legislature March 4 allows the State Board of Medical Examiners to grant licenses without any examination to physicians already licensed in some other state which has a standard equal to that of Minnesota. Each applicant for a license must pay a fee of $10, which the board may retain, regardless of the results of examination. It is made the duty of every county attorney to prosecute cases of practice without license whenever requested so to do by the board of examiners or any five of its members.

MISSOURI.

Library to Society.—The widow of Dr Marcus A. Bogie, Kansas City, has given his valuable medical library to the Jackson County Medical Society.

Personal.—Dr. Harry E. Ferrel, St. Louis. has been commissioned first lieutenant and assistant surgeon, N. G. M.——Dr. Moritz F. Weymann, in compliance with a request made by the board of directors of the Central Medical College, St. Joseph, has resigned as president and from the teaching force of the institution. Dr. O. Beverly Campbell was elected president for the unexpired term.

Testimonial Banquet.—The St. Louis Medical Society will give a banquet, April 14, in honor of Drs Simon Pollak, William Johnston, William M. McPheeters and J. B. Johnson, all ex-presidents of the society, and all over 80 years old. Dr. Simon Pollak is the oldest, the banquet being given on his eighty-ninth birthday. A large attendance is assured and the occasion is expected to be a most enjoyable one. Tickets to the banquet will cost $5 each and can be secured by addressing Dr. Frank L. Henderson, Century Building, St. Louis.

Damage Suits.—Dr Charles M. Coe, Kansas City, has been sued for $10,000 damages by Miss Minnie Bell of Saline County, who alleges permanent impairment of health and aggravation of disease by reason of the defendant's carelessness, negligence, etc.——University Medical College, University College Training School, Dr. Flavel B. Tiffany and Louis C. James, Kansas City, are made defendants in a damage suit for $5,000, filed by Mrs. Josephine Duzan, who claims that her husband's death was due to lack of proper treatment on the part of his attendants.

Street-Car Colds.—At a meeting of the St. Louis Medical Society, February 28, Dr. Fayette C. Ewing read a paper on "Street-Car Colds," and offered the following resolutions, which were unanimously adopted by the society:

Recognizing the fact that many colds and diseases of the respiratory organs are acquired by riding in draughty, ill-ventilated, cold and crowded street cars, wherein the element of time conspires to produce a prolonged chilling of the body, terminating in localized congestion and consequent respiratory catarrhal affections, it is hereby declared to be the sense of the St. Louis Medical Society that street car officials should take measures for a more uniform and equable temperature in their cars, with protection against draughts, and especially in such cars as run far out into the suburbs, where passengers must sit still for an extended period of time.

And it is further declared that such lines of cars as make long runs, compelling long-distance passengers to endure a temperature under 60°, be condemned as dangerous and a menace to the health of their passengers and their patrons, who are hereby warned to seek other means of conveyance.

NEW YORK.

Carnegie's Gift to Ithaca.—The offer of Andrew Carnegie to defray the expense of the new filtration plant at Cornell University, Ithaca, which will amount to about $150,000, has been accepted by the university.

Elsberg Bill Passes Senate.—The bill providing for the abolition of the coroner's office in New York, Kings, Queens and Richmond counties was passed by the senate, March 18, by a vote of 29 to 17. Senator Elsberg, who introduced the bill, was openly charged with having been actuated in this matter solely by personal spite.

Preventable Disease Mortality.—The mortality from preventable diseases during the year 1902 was 14 per cent. of the total, which was above the average of the last few years. This increase was largely attributed to the prevalence of smallpox, 442 of the deaths being from this cause. Typhoid fever caused 1,318 deaths, or 300 less than the average, and pulmonary tuberculosis 12,582, as against 13,270, the average for the past five years. The work of the Bureau of Pathology and Bacteriology seems to be appreciated, for the report states that applications for examinations of samples of water are becoming more and more numerous. The calls for the examination of foods and drugs can not be met without a greater appropriation from the legislature.

New York City.

The will of Dr. T. Gaillard Thomas has been filed for probate. It is believed that the value of the estate is about one million dollars. It is to be divided into thirds, one-third going to the widow and one to each of the sons.

Fighting Glanders.—The health commissioner has asked for an appropriation of $5,000 to enable the department to stamp out glanders, which is prevalent among the horses in the city. The disease was first discovered in an uptown boarding stable, and it was then learned that horses had been dying there of glanders for months, but no report had been made. It is said that from five to ten cases are reported daily in this city at the present time, and that the disease is also prevalent in the outlying districts. One man, a cigar maker, who is not known to have had any communication with horses, died of the disease at the Metropolitan Hospital.

Rabies Prevalent.—The recent death from rabies of Dr. Henry P. Loomis' son has directed attention to the prevalence of this disease not only among dogs but horses. Several well-known veterinary surgeons are responsible for the statement that several cases of rabies among horses had recently come to their notice. According to Dr. William H. Park of the health department, two physicians practicing on the West Side lost their horses on the same day from rabies. There have been four deaths from hydrophobia in this city in the past twelve months, and within the past few weeks no less than 13 persons have received the Pasteur treatment from the board of health.

Gifts to Hospitals.—The Manhattan Eye and Ear Hospital has received from the widow and children of Gen. Samuel Thomas a gift of $50,000, thus raising the new building fund to $100,000. The institution has outgrown its present quarters and desires to have a new building in the vicinity of Second Avenue and Fifty-ninth Street.——J. Rogers Maxwell has just offered to build, at his own expense, the two central sections of the proposed new building of the Long Island College Hospital as a memorial to his brother, Henry W. Maxwell, who was for a long time closely identified with the interests of the hospital. These two sections will form the main building on Henry Street. The buildings, when completed, will cost about one million dollars.

Buffalo.

Money for General Hospital.—William E. Brown has donated $10,000 for the Buffalo General Hospital.

The February Report.—The monthly report of the department of health for February shows a death-rate of 14.96 per 1,000 a year. The principal causes of death were as follows: Consumption, 43; diphtheria, 8; typhoid fever, 14; debility, 45; cancer, 21; apoplexy, 19; meningitis, 11; valvular heart disease, 29; pneumonia, 53; appendicitis, 6; cirrhosis of the liver, 7; gastroenteritis, 7; diabetes, 3; nephritis, 32, and violence, 24. The total deaths for February were 474, as compared to 392 for February, 1902.

PENNSYLVANIA.

Philadelphia.

Bills Defeated.—The Blumle bill to reward mothers of large families with gold medals and cash prizes and the Keppler antimiscegenation bill were both recently defeated in the lower branch of the legislature.

Resigns After Long Service.—Miss Marion A. Smith has resigned as directress of the Philadelphia Hospital Training School for Nurses after sixteen years' service to accept the superintendency in the University of Pennsylvania Hospital.

Contract Awarded.—At a recent meeting of the board of trustees of the Jefferson Medical College Hospital, the contract for the foundation and the structural steel work, as far as the first floor, was awarded for $99,485. The work will soon begin.

Homeopathic Hospital Postponed.—City councils have decided to postpone further consideration of the proposition to establish a city homeopathic hospital at the site of the present Municipal Hospital when the latter is removed to its new site in the Thirty-third ward.

Vital Statistics.—Typhoid fever showed a decrease for the week ended March 21, there being 74 fewer cases than in the preceding week. The total number of deaths from all causes was 535, as compared with 577 for the previous week, and 476 for the corresponding week of 1902.

Bequests.—The recent adjudication of the estate of William McClary shows a large number of charitable bequests, among them $5,000 to each of the following hospitals for the endowment of free beds: Protestant Episcopal, Presbyterian, German, St. Joseph's and Samaritan hospitals.——From a balance in the estate of J. Alfred Kay the following legacies were allowed: $5,000 each to the Pennsylvania, Germantown, Jefferson, University of Pennsylvania, Orthopedic and Polyclinic hospitals; to the German, St. Agnes', St. Joseph's, Gynecean, Howard, Medico-Chirurgical, Jewish, Hahnemann and Presbyterian hospitals, $1,000 each; a like amount went to the Philadelphia Dispensary and to the Howard Hospital and Infirmary for Incurables. One-sixth of the residuary estate not named is divided among the Pennsylvania, Jefferson, Germantown, University of Pennsylvania, Orthopedic, and Polyclinic hospitals.

UTAH.

Smallpox in State School.—Several cases of smallpox have been discovered in the Utah State School for the Deaf and Dumb and the institution has been placed under strict quarantine.

Want Medical School.—Physicians of Salt Lake City propose a medical college in connection with the state university. They have asked the board of regents of the university to co-operate and, if a favorable reply is received, the legislature will be asked to make an appropriation to establish this department.

Alleged X-Ray Injuries.—A. K. Hicks has brought suit for $20,000 damages against Dr. Samuel H. Pinkerton, Salt Lake City, alleging "negligent, careless and unskilful treatment of a gunshot wound with *x*-rays" whereby the flesh and bone of plaintiff's left leg is said to have been "burned, injured and destroyed."

Salt Lake City's Deaths.—The mortality of Salt Lake City for 1902 was 849, corresponding to an annual death rate per 1,000, of 11.32. The birth-rate for the same period was 16.98 per 1,000. Pneumonia caused 74 deaths; tuberculosis, 43; bronchitis, 24; Bright's disease, 40; heart disease, 49; meningitis, 36; paralysis, 38; diarrhea and enteritis, 45; appendicitis and peritonitis, 21; cancer, 29; diphtheria, 39; scarlet fever, 36 and typhoid fever, 28.

Contagious Diseases in Salt Lake City.—During 1902, 1,573 cases of contagious and infectious disease were reported, the mortality from which made up nearly 13 per cent. of the total mortality. There were 443 cases of scarlet fever with 36 deaths; 251 of diphtheria with 39 deaths; 97 of smallpox with one death; 167 of typhoid fever with 28 deaths; 507 of measles with 4 deaths; 101 of chickenpox without a death, and 7 cases of whooping cough with one death.

Mental Hospital Bill Progresses.—Mr. Spry's mental hospital bill passed the house. It provides for an assistant physician and other additional help, for daily visits by a physician to each patient; it changes the form of examination, provides for the limitation of commitment, allows no special care to be given to any inmate for extra pay and incorporates the most modern ideas of hospital treatment, regarding the insane as sick. The words "arrest" and "conviction" are no longer used.

WASHINGTON.

Physician's Office Robbed.—Burglars recently entered the office of Dr. Guy S. Peterkin, Seattle, and secured $184 from his desk.

Forfeited His Bond.—F. C. Goodale, Spokane, charged with practicing medicine without a license, failed to appear, March 5, for trial, and his bond was forfeited.

Grip Epidemic in Tacoma.—Influenza is said to be epidemic in Tacoma. The rules for its prevention as summarized there are: Nourishing food; plenty of sleep; cleanliness of person and avoidance of stimulants.

Smallpox at Colfax.—Colfax has 16 cases of smallpox, not 31, as was reported. Schools have been closed, public gatherings interdicted and children are not allowed on the streets. It is noted that the disease is confined to boys between 16 and 19 years of age.

WISCONSIN.

Diploma Stolen.—The diploma of Dr. Adolph Roos, Oshkosh, was recently stolen from his office.

Schools Closed.—On account of the prevalence of varioloid, diphtheria and scarlet fever in Baraboo, the local schools have been closed.

Emergency Hospital's Work.—The report of Emergency Hospital, Milwaukee, for the past year shows that 910 cases were treated, 819 of the patients being males, and 655 of the cases surgical. In 9 cases the patient died before reaching the hospital.

Personal.—Dr. Richard Schorse, Milwaukee, has been appointed resident physician at the University of Pennsylvania Hospital, Philadelphia.——Dr. Richard Dewey, Wauwatosa, has been elected president of the honorary medical staff of the Milwaukee County Hospital for the Chronic Insane.——Dr. Arthur J. Patek has been selected as chief of the attending staff, and Dr. Alfred H. Levings, chief of the consulting staff of the Jewish Hospital.——Dr. B. C. Gudden has associated with him in the management of the Oshkosh Clinic, Dr. J. A. Crum.

In the Hands of the Law.—C. B. Savnac, an itinerant corn doctor, has been arrested at Green Bay, charged with practicing medicine without a license.——Dr. George G. Gregory is held in jail at Madison, awaiting the extradition papers from Michigan, where he is wanted on a charge of perjury.——Dr. B. Fowler Baker, Milwaukee, charged with violating the health law, was arraigned in the District Court, March 5, and his case continued until March 14.——Louis Tauvar, an Italian dentist of Marinette, was arrested recently, charged with practicing medicine without a license.

GENERAL.

American Beds in French Hospital.—Victoria Hospital, Nice, France, has received $2,500 from Mrs. Robert Goelet, New York, to endow an American bed. Another was endowed by Andrew Carnegie five years ago.

A Merited Promotion.—By a special act of congress Major William C. Gorgas, surgeon U. S. Army, who made so brilliant a record by his sanitary work in Havana, has been promoted to colonel and assistant surgeon-general.

New Red Cross Head.—Rear Admiral William K. Van Reypen, U. S. N., retired, former surgeon general of the Navy, has been named as the successor of Miss Clara Barton as president of the American National Red Cross Society.

Promotions Prior to Retirement.—The Army papers announce that preliminary to retirement Colonels Charles Smart, Peter J. A. Cleary, Henry Lippincott and Calvin De Witt, assistant surgeons-general, are to be promoted to the rank of brigadier-general.

Plague Continues to Decrease.—The use of the Haffkine, and especially the Yersin, serum, in Mazatlan are putting a decided check on the fatality of the plague. Deaths average only from one to three a day now. Some days there are none. Up to March 13 the total number of cases was 313 and the deaths 255. About $130,000 has been thus far spent in relief of the needy. Without the money contributions it would have been impossible to proceed with the wholesale destruction of infected houses and other measures that fall heavily on the poorer classes. Plague now exists at Villa Union, Siquieros and Rosario.

FOREIGN.

Smallpox in Trinidad.—This island is suffering from an epidemic of smallpox, widespread and rapidly extending.

Russian Medical Students at Berne.—The Russian medical students at Berne, both male and female, far outnumber those of Swiss and other nationalities. The Swiss claim that they are crowded out and demand measures to regulate this afflux of Russians.

Changes in the German Universities.—Dr. Hackenbruch has been invited to take charge of St. Joseph Hospital at Wiesbaden in the place of the late Professor Cramer.——Kreibich of Vienna has been appointed professor of dermatology, and von Hacker of Innsbruck, professor of surgery at Graz.

Trachoma Prevents Visitors' Return.—Some travelers in Italy are refused transportation back to America because they

are afflicted with trachoma and the authorities fear that others on shipboard might take the disease. They are said to be American citizens and to take their detainment in ill humor.

Honors for Koch.—The Paris Académie des Sciences recently voted for a foreign associate member in the place of Virchow. The names proposed were: Robert Koch of Berlin, Agassiz of Harvard, Langley of Washington, and Van der Vals of Amsterdam. Koch was chosen, having received 26 and Agassiz 18 votes.

Russian Isolation Houses.—St. Petersburg will soon celebrate its two hundredth anniversary by the erection of a stone building to serve as a temporary home for the healthy inmates of infected houses while the latter are being disinfected. It will accommodate 100. There are already three such buildings, with a capacity of forty each.

Responsibility for Erysipelas in a Hospital.—Our Russian exchanges mention that the widow of an Odessa architect has sued Dr. Jansen and the managers of a hospital at Berlin for nearly $50,000. The architect entered the hospital for an operation, which was successful, but he contracted erysipelas, to which he rapidly succumbed The widow claims that the erysipelas might have been prevented by due care.

Institute for Post-Graduate Courses at Berlin.—The organization of the free post-graduate courses which are now being held each year in twenty-three large cities in Germany owes its inception to the late Empress Frederick. It is now proposed to found a special institute in Berlin as a memorial to the empress, which will serve as a center for the movement and for housing the collections, etc., which can thence be dispatched as needed.

Baudouin at the St. Louis Exposition.—Dr. Marcel Baudouin of Paris has been made a member of the committee on admissions to the St. Louis Exposition and expects to remain in this country several months. He is the founder of the unique "Institut de Bibliographie," also the editor of the "Gazette Med. de Paris" and the "Bibliographia Medica." He is the moving spirit in the "Agence de la Presse Scientifique Internationale" and has published several important works alone or in collaboration with others. He visited this country at the time of the Columbian Exposition.

Burlesque Number of the "Munich Med. Wochenschrift."—This interesting "Scherznummer" is equal to its five annual predecessors. Recent occurrences in Germany afford apt subjects for satire. One communication, purporting to be from Nardenkötter's clinic, is entitled "The Bath Tub in the Pharmacopeia." It refers to the fact established at the trial of this charlatan that he compounded his medicines in the family bath tub. "A Rare Case of Pneumonia" is described in detail, exidently copied verbatim from the latest text-book. Its rarity was due to the slimness of the writer's practice. "Progress in Homeopathy" describes the limitations hitherto imposed on homeopathists by the difficulty of writing figures with as many ciphers as are necessary to express their dilutions. This has been remedied now by substituting for the figures the figure representing the quantity of ink required to write them. Further progress has also been realized by the results obtained with river water, to which one drop of the mother dilution of croton oil was added several miles above. After drinking six quarts of this river water in twenty minutes, diuresis was promoted to a remarkable extent, thus establishing the hitherto unsuspected value of croton oil as a diuretic when administered on the Hahnemannian principles. "Metallodiscotherapy in Nervous Affections," portrays the remarkable benefit to be derived in inanition and nervous depression, by application of a silver or gold disc, bearing the impress of the mint, and applied to the chest in a leather bag like the "mercolint aprons." One article announces that the sick-benefit societies will soon be able to dispense with nearly all their professional medical assistance, as they are planning to introduce the plan of treating all the sick by streets. All in the first street will be treated by sun baths; on the second by hypnosis; on the third by bromids and opium; on the fourth by mercurial inunctions, and so on. A new infallible remedy for constipation is announced. The patient swallows a silver ball fastened to a celluloid thread wound on a spool. The course of the ball is traced by radiography, and when it emerges the length of the alimentary canal can be estimated by the thread. It is left in the body, the upper end tied to the ear, and the permeability of the intestinal canal can be maintained by sawing it back and forth It is possible also to clean out the alimentary canal by tying a brush to the thread and pulling it through. The idea of the thread is patented under the name "Entero-cathartor." Among the advertisements we note that of the new prepared food "Sana," said to be recommended by Hippocrates where he wrote: "Mens sanus in corpore sana," viz., "That man alone is healthy who has sana in his body."

LONDON LETTER.

The Regulation of Cremation.

A report has been issued by a departmental committee appointed by the home secretary to prepare regulations to be made under the Cremation Act passed last year. The object was to frame regulations which, while avoiding unnecessary restrictions such as might discourage cremation, would reduce to a minimum the risk of cremation being used to destroy the evidence of murder. The committee studied the records of cases of murder in which evidence had been obtained by the exhumation of the remains, and directed special attention to the certificates or other evidence of the cause of death that had been produced before the burial. They disclaim the idea that any possible restrictions can guard completely against the risk of cremation being used for the concealment of crime. But they think that regulations can be framed which will so far reduce the risk as to make cremation at least as safe as burial. The committee has come to the conclusion that the person to decide on the cremation should be a medical referee, specially qualified for the work and appointed by the cremation authority. Before cremation is permitted there should in every case be a personal inquiry by someone beside the medical attendant of the deceased. If the medical referee can not make the actual inquiry there ought to be a second certificate by an independent person, who should be a medical man, either nominated for the purpose by the cremation authority or holding one or other of the following appointments: Medical officer of health, police surgeon, certifying factory surgeon, medical referee under the workmen's compensation act, or physician or surgeon to a large public general hospital. In every case there should be required either (1) two certificates, one given by the medical attendant, the other by an independent person—the medical referee, or a doctor nominated by the cremation authority, or a person holding one of the public appointments mentioned above; or (2) a certificate given after a postmortem by a pathologist named by the cremation authority, who may or may not be the medical referee; or (3) a certificate by a coroner given after an inquest. If the certificates under heading 1 do not show the cause of death definitely and in such terms as to exclude the possibility of poison or violence as the cause of death, the cremation should not be allowed unless a postmortem has been held and a certificate given as under 2. If this does not sufficiently reveal the cause of death, and if the relatives still desire cremation, there must be an inquest. The postmortem should be made by a pathologist, nominated by the cremation authority, who should be a person accustomed to make postmortem examinations. The medical attendant of the deceased, or some other medical representative of the applicant for cremation should be allowed to be present. If, though the cause of death be definitely ascertained, there still remain any suspicious circumstances in the case, the coroner should be referred to, and where a case has been referred to the coroner, cremation should not take place unless, after holding an inquest, he can give a certificate stating definitely that no circumstance exists which could render necessary any further examination of the remains.

Mistakes in the Diagnosis of Infectious Diseases.

The committee of the Metropolitan Asylums Board has issued a most interesting report showing the cases of mistaken diagnosis sent to their board's hospitals during the last three years. In 1899 1,583 cases were sent which were not notifiable diseases—a percentage of mistakes of 6.3. In 1900 the number was 1,706, a percentage of 7.9; and in 1901 the number was 2,365—a percentage of 9.2. The percentage on the total cases for scarlet fever, 5.6; diphtheria 12.8, and typhoid fever 25.5. Among the diseases diagnosed as scarlet fever were measles, rubella, tonsillitis and erythema. Measles was returned as diphtheria in 47 cases, and tonsillitis as diphtheria in 880 cases. Among the cases wrongly certified as typhoid fever were 13 of influenza, 22 of febricula, 9 of bronchitis, and 86 of pneumonia Of notified cases of smallpox the diagnosis was mistaken in 13 per cent. of the cases.

Poisoning by Illuminating Gas.

The modern method of mixing coal gas with "water gas" greatly increases the amount of carbon monoxid in the gas supplied for illumination. Hence an alarming increase in the number of cases of carbon monoxid poisoning has recently

taken place. The latest fatality has been reported from Dublin where a man and his wife were found asphyxiated in their room—the former in a dying state, the latter dead. Prof. E. J. McWeeney examined the blood and found it was saturated with carbon monoxid and gave the spectroscopic indication. Within a short period 6 deaths from this cause have occurred in Dublin. In this particular case the bedroom was insufficiently ventilated and the deceased came from a remote town in Ireland where gas had not been introduced. No doubt their want of familiarity with its use was a source of danger.

Typhoid Fever from Sewage Contaminated Shell Fish.

We have already briefly referred to this subject in THE JOURNAL. As long as twenty-three years ago Sir Charles Cameron, health officer of the City of Dublin, read a paper at the British Medical Association on "Typhoid from Oysters," but the subject attracted no attention until 1895, when it was revived by Sir William Broadbent, who recorded a number of cases of typhoid fever which he attributed to contaminated oysters. In 1896 Dr. Bulstrode, Dr. Klein and the late Sir R. Thorne Thorne reported to the government on the question and, as a result, a bill to regulate the oyster trade was introduced into parliament. But it was withdrawn owing to certain administrative difficulties. Interest in the subject again languished until the recent outbreaks of typhoid fever in several parts of England, attributed to shell fish. In London a scare has been produced and the oyster trade almost completely paralyzed by the publication of the medical officer of health's report. Four cases of typhoid fever were brought under his notice which appeared to be due to cockles bought at the great fish market of Billingsgate. In samples of these cockles Dr. Klein, the bacteriologist, found evidence of sewage contamination—the *Bacillus coli communis*, and spores of the virulent *Bacillus enteritidis sporogenes* in abundance. From one cockle he isolated the typhoid bacillus. Even "cooked" cockles contained numerous living organisms. These mollusks are not boiled sufficiently long to raise their interior to 160 F. —at which the typhoid bacillus and all the bacilli of the colon group perish—because they would be rendered tough and unsaleable. It appears that the whole estuary of the Thames is polluted by sewage. Hence, not only shell fish but sprats, whitebait and smelts, which are eaten "uncleaned," must be a source of danger. Numerous other outbreaks of typhoid fever have been traced to cockles. In 1902 twenty-six cases occurred in Westminster. An outbreak of typhoid fever, due to oysters, occurred at Winchester. After a banquet on November 10 ten persons were attacked on the same evening with violent diarrhea and the illness developed into typhoid fever. As it was not thought possible for the disease to have been conveyed by cooked food suspicion fell on the oysters. All the ten patients had eaten them, though several other persons had also done so with impunity. Investigation showed that the sewage of the town of Emsworth entered the river only fifty yards from the oyster pits and practically flowed over them. Dr. Klein found excrementitious matter, but not the typhoid bacillus, in the oysters and in the water taken from the pits. About the same time an outbreak of thirteen cases of typhoid occurred at Portsmouth, and several of the patients had eaten oysters from the same pits. Subsequently Dr. Klein examined eighteen samples of oysters taken from five different fisheries and found eleven contaminated with sewage. The medical officer of health of London strongly urges the necessity for legislation to prevent the contamination of shellfish by sewage.

The Liverpool School of Tropical Medicine and the Prevention of Malaria.

The energetic Liverpool School of Tropical Medicine has drawn up a set of simple instructions for the prevention of malaria to serve as a guide to Europeans living in tropical countries. They are advised to invariably sleep within mosquito curtains of a mesh of not less than ten holes to the inch and to tack on a piece of material all around the net above the level of the mattress, so as to protect the limbs from bites through the net during sleep. Mosquito boots to protect the ankles during sleep are also recommended. At least 15 gr. of quinin should be taken weekly. The quarters provided for the European members of a firm should possess at least one sitting room or portion of a veranda securely protected by screens of wire gauze against the entry of mosquitos. This should be the room commonly used by the inmates from sunset to bedtime. The office and dining room should be provided with punkahs or electric fans, to be used during office hours and during meals. The premises of the firm should be provided with at least one rubbish bin (with a cover). All cisterns and other vessels for the storage of water should be furnished with accurately fitting covers and wire-gauze caps to the pipes for the purpose of excluding mosquitos. All open and permanent collections of water really required for irrigation, washing or other purposes should be treated once a week with kerosene oil for the destruction of larvæ. The school also intends to arrange a course of lectures on the prevention of tropical diseases for clerks, missionaries and others proceeding to the tropics. Each course will consist of five lectures, extending over two weeks in the months of January, May and November.

Smallpox in England.

Cases of smallpox continue to occur in various parts of the north of England. Over 300 cases are under treatment in Liverpool, and the disease is also rife in Salford and Leeds. It has also broken out in a jail at Birmingham. In the south of England six cases have occurred in one family in Devonshire. In London a man was found by the police in a dying condition in the streets. He was taken to an infirmary, where the cause of disease was found to be hemorrhagic smallpox.

Correspondence.

Tropical Medicine.

PHILADELPHIA, March 21, 1903.

To the Editor:—I am extremely glad to see your editorial on Tropical Medicine in the last issue of THE JOURNAL. I have been much pleased with the interest which has been shown in the study of tropical medicine and surgery of late in the United States. This winter, the Jefferson Medical College founded a lectureship, which was purely voluntary for the senior class, no examinations were held on it, nor was attendance essential to graduation. I expected, perhaps, that a dozen men would attend the lectures of Captain Kieffer of the Army, who gave the lectures for us. Instead of a dozen about 150 men (nearly the entire senior class) attended and showed the greatest possible interest in the subject. The junior class also requested the privilege of attending. The Washington Post-Graduate Medical School opened a similar course the following week, and I believe in Chicago a third course has been established.

This movement has been followed also by the organization of a Society for the Study of Tropical Medicine and Surgery in Philadelphia. Your suggestion that the American Medical Association can not overlook this subject in any future program is certainly wise. Not only is the profession in the subtropical portions of America interested in the subject most vitally, but our new possessions in Hawaii, the Philippines and Porto Rico, our very intimate affiliations with Cuba, and the very early establishment of the Panama Canal with a large population of Americans in Central America make it imperative that the Association should give considerable attention to this subject.

I trust that it will be brought before the Association at the New Orleans meeting by the proper authorities, and, as seems to me best, that a Section on Tropical Medicine and Surgery shall be established. It would be, I fear, an inefficient way to deal with a large subject to have it divided among a number of sections, medicine, surgery, pathology, ophthalmology, etc. This, however, is for the Association itself to decide. The main thing is that the subject shall be properly considered.

W. W. KEEN.

Michigan Students Protest.

ANN ARBOR, March 21, 1903.

To the Editor:—On behalf of the faculty and students of the Department of Medicine and Surgery of the University of Michigan I wish to enter a most vigorous protest against your editorial on page 787. [THE JOURNAL, March 21.] You endeavor to apparently keep within the bounds of truth and at the same time you give a wholly false impression. You start by saying that the students of "certain medical colleges of that state" (Michigan) have protested against the passage of the proposed medical act, and after very properly condemning the position of such students, you wind up with the following: "We hope the students of the Michigan medical colleges will

see the unwisdom of their action and assist, rather than oppose, those who are fighting for the elevation of the standard of the profession which they are about to enter." This statement implies that the protest against the passage of the act has been made by a large number of medical students in the schools of Michigan, and such an implication is not only unjust, but is absolutely false. The students of the Department of Medicine and Surgery of the University of Michigan are not politicians and have never attempted in any way to influence legislation. They are otherwise engaged and have no time to send delegations to Lansing. Moreover, both the student body and the faculty of this school are in favor of the proposed amendment, and the graduates of this school are perfectly willing that their record before the examining boards of this country should be compared with the records of any other medical school in the country. So far as I know the protest has come from only one medical school, and it is unfair for you to condemn the medical students in the schools of Michigan as a whole on account of the action taken by students from one school. When you make charges of the kind made in your editorial you should be more specific and exact.

Yours respectfully, Victor C. Vaughan.

[Dr. Vaughan evidently has not kept in touch with what is going on in his state or he would not say that "the protest has come from only one medical school." We have positive information as regards four, and indirect regarding the other. (There are five colleges in the state aside from the University of Michigan.) As a rule the senior students, as those graduating this year would probably be exempt, are taking no action; and the faculties are generally against the students' actions. We are glad to know that the students of the Department of Medicine and Surgery of the University of Michigan are not among those who are protesting.—Editor.]

May We Not Secure Immunity from Fatal Chloroform Narcosis?

Indianapolis, March 19, 1903.

To the Editor:—Chloroform, pleasant to take, quickly producing thorough muscular relaxation and complete insensibility to pain, would be the ideal anesthetic were it not for the dangers attending its use. These dangers arise so quickly that the system is overwhelmed before the anesthetist realizes that death is impending. Fatalities occur, not necessarily when large amounts of chloroform are used, but when gasps and deep inspirations fill the innermost alveoli with the concentrated vapor. Various apparatuses have been devised to properly dilute the vapor, but none has been altogether satisfactory.

Parturient and pregnant women seldom, if ever, succumb to chloroform narcosis, for the following reasons:

1. In the parturient the central nervous system is in a state of congestion.

2. In both the pregnant and the parturient movement of the diaphragm is greatly restricted because of abdominal distension; therefore, breathing is necessarily shallow. As a consequence, chloroform would have to be given in very concentrated vapor, indeed, to prove dangerous to the patient, for it must be greatly diluted by admixtures with the residual air of the lungs previous to absorption and, in such cases, the shallow respiration would make it practically impossible to overwhelm the patient with an overdose in a few respirations.

In view of these facts, would it not be wise before the administration of chloroform to artificially restrict the movements of the diaphragm? An abdominal bandage, preferably an elastic bandage, would assure shallow breathing, and it would appear, secure at least the immunity from "drowning" in chloroform which belongs to the pregnant and the parturient. H. W. Dudley, M.D.

Eye-Strain and the General Practitioner.

Chicago, March 23, 1903.

To the Editor:—Referring to your review in The Journal of March 14 of Dr. Gould's book, "Biographic Clinics," dealing with the question of eye-strain and its effects, I can not but think it unfortunate that you should adopt such a critical attitude, because the general impression left in the mind of the reader will be that oculists are very prone to exaggerate the importance of eye-strain, and that in the absence of very direct indications the counsel of an oculist will be deemed superfluous and be dispensed with.

It may be that Dr. Gould's claims are excessive, but as a general practitioner I do most certainly know that not nearly enough of our patients are referred to the oculist. Provided that a conscientious and skilled refractionist be employed, the fee and time spent in the examination are the only losses to the patient, yet many patients who could well afford these if it were only to exclude the possible culpability of the eye, are allowed to suffer needless tortures for years because of the ignorance or thoughtlessness of the general practitioner, or sometimes his jealousy of the specialist.

As a general practitioner I have seen so much relief afforded patients by the wearing of properly-fitted glasses, and in such very unexpected ways, that I feel very keenly on this subject, and for this reason am inclined to resent anything that tends to relieve the physician of his responsibility to his patient or encourages him to undervalue the exceeding importance of eye-strain in causing disturbances anatomically remote from the eye and very various in kind. The judicious employment of the services of an expert refractionist—and competency of the highest order is a sine qua non in refraction work—will rob the practitioner of many of his chronic cases, and in place of fees he will have to be content with gratitude—if the oculist does not get all of that. Our duty, however, is none the less clear. Very truly yours, James W. Walker, M.D.

Newspaper Reputation.

Chicago, March 24, 1903.

In view of the surprising and, to some of us, painful newspaper publicity that characterized the now famous visit of Professor Lorenz to this country, the following clippings from the daily papers are of interest:

"DR. MUELLER PERFORMS FOUR OPERATIONS.

Dr. Frederick Mueller, the pupil of Dr. Lorenz, performed four of the most difficult operations for congenital dislocation of the hip, in Beth Israel Hospital to-day," etc., etc.—New York Letter, the *Chicago Tribune,* March 15, 1903.

"LORENZ MACHINE IS USED SUCCESSFULLY.

For the first time in this country the Lorenz machine has been used in an operation for hip disease. The operation was performed by Dr. Frederick Mueller, a pupil of Dr. Lorenz," etc., etc., etc.—New York Letter, *Chicago Record-Herald,* March 17, 1903.

"DR. MUELLER IS BACK. ASSOCIATE OF DR. LORENZ WILL PRACTICE ORTHOPEDIC SURGERY HERE.

TO REMAIN PERMANENTLY.

NOTED VIENNA SURGEON WILL BECOME A CITIZEN AS SOON AS LAWS PERMIT."

—*Chicago Record-Herald,* March 23, 1903.

And then follows a third of a column, including what purports to be an interview with Dr. Mueller, the substance of which is that he likes this country so much that he couldn't stay away; that "There is a great field here for orthopedic surgery. Chicago is centrally located, and people will flock here for treatment from all over the country."

These are but samples taken from the public press. Each of them contains what purports to be some interview with Dr. Mueller.

How long will it be before it is learned that such newspaper attentions, however profitable from a business standpoint, are not accepted by medical gentlemen in this country?

W. A. Pusey.

Marriages.

Deyo L. Ramsdell, M.D., Lincoln, Neb., to Miss Gertrude Musser of Orangeville, Ill, March 9.

Samuel Craig Plummer, M.D., Chicago, to Miss Mary Louisa Middleton, daughter of the late Dr. W. D. Middleton of Davenport, Iowa, March 18.

Carlton Lee Starkweather, M.D., Occoquan, Va., to Miss Jennie Atkinson Jones, daughter of the late Elias Jones, M.D., of Fairfax Courthouse, Va., at Trinity Church, Washington, D. C., March 12.

Deaths.

Edward Watrous Jenks, M.D., of Detroit, died suddenly, March 19, on a Wabash train between Chicago and Detroit, after an illness of five days, from pneumonia, aged 69. Accompanied by his daughter he had been taking a pleasure trip through Mexico. While visiting the Grand Canyon he took cold, and when he reached El Paso, pneumonia developed. Despite the advice of his physicians he persisted in returning to Detroit, but died on the train two hours after leaving Chicago. He was born March 31, 1833, in Victor, N. Y., and was graduated from Castleton (Vt.) Medical College in 1855; he also received a degree in medicine from Bellevue Hospital Medical College, New York, in 1864. The degree of LL.D. was conferred on him by Albion (Mich.) College in 1879. He established himself in practice in Detroit, and in 1864-65 was assistant surgeon in the military hospital, Detroit. He was one of the founders of Detroit Medical College, its president in 1868-69 and professor of obstetrics and diseases of women. From 1871 to 1875 he occupied this chair in the Medical School of Maine, Bowdoin College, and in 1879 was appointed professor of gynecology in Chicago Medical College, succeeding Dr. William H. Byford. He was a fellow of the London Obstetrical Society; one of the founders of the American Gynecological Association; a member of the American Medical Association; member and formerly president of the Michigan State Medical Society, and of the Detroit Academy of Medicine; member of the Detroit Gynecological Society; member of the Detroit Medical and Library Association, and of the Wayne County Medical Society. He was also an honorary member of the Maine Medical Association, Ohio State Medical Society, Cincinnati Obstetrical Society, and Upper Peninsula (Mich.) Medical Society. He was at one time a member of the State Board of Charities and Corrections. He was for several years surgeon-in-chief of the Michigan Central Railroad. He was one of the founders, and for four years editor of the "Detroit Review of Medicine." Dr. Jenks was one of the eminent gynecologists of his time, and made a special study of the history of gynecology. The "Detroit Free Press," in its issue of March 20, pays the following tribute to the memory of Dr. Jenks:

> Michigan and Detroit have suffered a distinct loss in the death of Dr. Edward W. Jenks. In the widened relations of life, he was the old-school gentleman, courteous, considerate and charitable at all times. He carried his ideals into his professional and public life. In the sociological circles of the state Dr. Jenks will be specially missed. He had given much time to the work of correction and charities. He was a careful student of pauperism and crime. He was deeply interested in penology, and had accomplished much towards sustaining interest in the charities and corrections of the state.
>
> To the children of Michigan Dr. Jenks was a firm, faithful and intelligent friend, and particularly was he the friend of the children of the poor and the unfortunate. Much of the energy of his later life was given to the effort to establish a home for crippled and dependent children. All his theories of organized charity and corrections were based on the belief that reform must begin with the child; that unfortunate children of all kinds should be the object of the state's tenderest solicitude; that those who could be trained into useful members of society should be so trained; that those who could not, should be isolated in such a manner that they would present the least possible menace to the physical and moral health of future generations. All this was a labor of love with Dr. Jenks, who contributed lavishly of his money, his time and his energy to the service of society, and it is not extravagant to say that the state of Michigan is far poorer by reason of his death.

Samuel W. McJunken, M.D. Medical College of the State of South Carolina, Charleston, 1875, assistant physician at the North Texas Hospital for the Insane, and previously a medical officer in the Navy, died from erysipelas at his home in Terrell, Texas, Mach 8, after an illness of one week, aged 48. He was a member of the Dallas Medical and Surgical Society, which passed appropriate resolutions at a special meeting held March 9.

Peter Klein, M.D. Geneva (N. Y.) Medical College, 1846, one of the oldest physicians in Detroit; county physician in 1847 for six years; in the United States' service during the Civil War, twice city physician, and twice a representative of Wayne County in the legislature, died at his home in Detroit from paralysis, after an invalidism of five years, March 15, aged 89. He had relinquished active practice ten years before.

John G. Giles, M.D. Faculty of Medicine of Queen's University and Royal College of Physicians and Surgeons, Kingston, Ont., 1860, of Athens, Ont., died in the General Hospital, Brockville, Ont., March 12, from kidney disease, aged 69. He was a member of the Provincial Legislature in 1876.

George Washington Le Cato, M.D. University of Maryland, Baltimore, 1860, of Wachapreague, Accomac County, Va., for many years a practitioner of New York City, and since 1893 a member of the Virginia senate, died at Richmond, Va., March 12, aged 61.

Charles A. McCall, M.D. University of Pennsylvania, Philadelphia, 1855, died from influenza at his home in West Philadelphia, after a brief illness, aged 65. He served through the Civil War and had charge of the Mount Pleasant Hospital, near Washington.

Clayton T. Hall, M.D. Medical College of Ohio, Cincinnati, 1889, died at his home in Mason, Ohio, March 11, from septicemia from an infected wound received while incising a carbuncle, aged 36. He was a member of the American Medical Association.

Samuel H. McLean, M. D. Eclectic Medical Institute, Cincinnati, 1874, superintendent of the Illinois Asylum for Feeble-Minded Children, Lincoln, Ill., died at that institution, March 18, after an illness of two years, aged 53.

Nathan Udell, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1855, for many years a practitioner of Centerville, Iowa, and twice state senator, died at the home of his son in Denver, March 6, aged 86.

Frank Fontelle Brigham, M. D. Harvard Medical School, Boston, 1885, a member of the staff of the Lynn Hospital, died from heart disease at his home in Lynn, Mass., after a brief illness, March 10, aged 40.

Alvin Jayne Cole, M.D. University of Michigan, Ann Arbor, 1860, surgeon of the Fourteenth Michigan Volunteer Infantry throughout the Civil War, died at his home in Fort Madison, Iowa, March 6, aged 65.

Albert E. Gangloff, M.D. Cleveland Homeopathic College, 1900, of Pittsburg, Pa., died from pneumonia, March 12, after a short illness, at the home of his brother in Mount Washington, Pa., aged 25.

Noyes Barstow, M.D. Vermont Medical College, Woodstock, died at his home in Springfield, Mass., March 16, from pneumonia, after an illness of five weeks, aged 82. He retired from practice in 1885.

Liberty M. Chilton, M.D. St. Louis Medical College, 1877, died at his home in Stanberry, Mo., March 9, from paralysis, after an illness of three days, aged 63. He retired from active practice in 1898

Walter W. Bunyan, M.D. Northwestern University Medical School, Chicago, 1901, an interne at Cook County Hospital, died from pneumonia at Wesley Hospital, Chicago, March 16, aged 26.

Almer M. Collins, M.D. Medical College of Ohio, Cincinnati, 1874, clergyman, mathematician and physician, died at his home in Shelbyville, Ill., March 10, from Bright's disease, aged 58.

John G. McPherson, M.D. University of Edinburgh, Scotland, 1848, of Manistee, Mich., died in a hospital in Milwaukee, March 10, aged 77. He served as surgeon during the Civil War.

Rolla W. Selby, M.D. Rush Medical College, Chicago, 1885, of Odebolt, Iowa, died in St. Joseph's Hospital, Sioux City, Iowa, February 15, after an operation for appendicitis, aged 42.

Braxton Banks, M.D. Jefferson Medical College, Philadelphia, 1889, died from pneumonia, after an illness of two weeks, March 12, at his home in Garner, Wake County, N. C., aged 50.

T. Harper Rice, M.D., M.R.C.S. London, 1901; M.R.C.P. London, 1902, died at the home of his parents in Pottstown, Pa., March 14, from tuberculosis, after a long illness, aged 29.

De Forest Hunt, M.D. New York University, 1864, died at his home in Grand Rapids, Mich., March 10, from cancer of the stomach, after an illness of two years, aged 61.

Kinsman D. Broga, M.D., an eclectic physician of Oneida, N. Y., died at his home in that city, March 11, from angina pectoris, after a short illness, aged 73.

Chauncey M. Skinner, M.D. Rush Medical College, Chicago, 1876, of Hartland, Wis., died suddenly from heart disease at Oconomowoc, Wis., March 14, aged 65.

Albert B. McKee, M. D. Rush Medical College, Chicago, 1893, died at his home in Edwardsville, Ill., March 17, from morphin taken with suicidal intent, aged 40.

Lavoisier H. Gratigny, M.D. Starling Medical College, Columbus, Ohio, 1864, died at his home in Cincinnati, March 7, from congestion of the brain, aged 62.

Fastus A. Snear, M.D. Cincinnati College of Medicine and Surgery, 1872, died at his home in Bryan, Ohio, March 10, after a lingering illness, aged 53.

Alfred D. F. Donkle, M.D. University of Illinois, 1901, interne at Augustana Hospital, Chicago, died from empyema at Augustana Hospital March 13.

Patrick N. Kelly, M.D. McGill University, Montreal, 1884, of Wabasha, Minn., died at the home of his parents, Pine Island, Minn., March 14, aged 46.

Julian H. Jones, M.D. Hahnemann Medical College, Philadelphia, 1860, died at his home in Bradford, Vt., March 3, from Bright's disease, aged 64.

Beverly P. Morriss, M.D. University of Pennsylvania, Philadelphia, 1849, died at his home near Ebenezer Church, Amherst, Va., March 7, aged 80.

G. A. Rebman, M.D. University of Maryland, Baltimore, 1875, died at his home in Wrightsville, Pa., March 9, from consumption, aged 50

Sherburne R. Merrill, M.D. Jefferson Medical College, Philadelphia, 1854, died at his home in Paterson, N. J., March 16, aged 81.

Norman H. Getman, M.D. Homeopathic Hospital College, Cleveland, 1854, died recently at his home in Richfield Springs, N. Y.

John Oscar Lewright, M.D. Missouri Medical College, St. Louis, 1887, died recently at his home in St. Louis, aged 36.

William Hunter, M.D. Homeopathic Hospital College, Cleveland, 1864, died at his home in Blairsville, Pa., March 13.

Levi C. Hubbard, M.D. Albany Medical College, 1882, died recently at his home in Carthage, N. Y., aged 66.

Deaths Abroad.

Manuel Barros Borgono, M.D., the eminent Chilean surgeon and rector of the University of Santiago, Chile, died recently in that city.

Mateo Gonzalez, M.D., dean of the medical profession of Morelia, state of Michoacan, Mexico, and for many years director of the school of medicine in that city, died March 5, after a protracted illness.

M. Crisafulli, M.D., who graduated at Messina and after several years of study in Paris and London at the expense of the municipality of Messina, returned to be professor of medicine, died there, February 19, after a brief illness, aged 77.

Dr. Ferdinand Weyert, senior physician and chief of the directorate of the St. Petersburg Eye Institute, an eminent ophthalmologist, died at his home in St. Petersburg, February 3, after a brief illness, aged 66. He was graduated from the University of Dorpat, pursued post-graduate studies in Vienna, Paris and Berlin, where he was a student of Albrecht v. Graefe, and on his return to St. Petersburg became connected with the Eye Institute, of which he was an honored official for more than forty years.

Dr. Adolf. Gessner, professor and director of the Frauenklinik at Erlangen, died recently, aged 39. In 1890 he was assistant to Prof. Dr. Frommel, from 1893 to 1897 was assistant physician in Olshausen's clinic, and then established himself in Erlangen, where he again became assistant and associate professor. In 1901 he was made director of the gynecologic clinic and professor of obstetrics. He was a thorough student, a clear and entertaining teacher, and a worthy and lovable man of great promise. He wrote the section on sarcoma of the uterus in Veit's Lehrbuch, and also was the author of a well-written and well-known treatise on asepsis and antisepsis in obstetrics.

Queries and Minor Notes.

Anonymous Communications will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

TREATMENT OF POISONING BY FORMALIN.

Billings, Mont., March 17, 1903.

To the Editor:—Will you please inform me what is the best antidote for formalin? The reason I ask is I had a case of a little boy a few days ago that drank about one ounce. Cliff Lindsey.

Ans.—Acetate of ammonia is reported beneficial, as well as dilute ammonia water cautiously administered. Beyond this follow the treatment of acute alcoholic poisoning; if necessary, maintain the body temperature with external heat, the respiration by atropin, the heart by strychnin. Of course, remove all the drug remaining in the stomach. If the vapor of formaldehyd has been inhaled, cautious inhalation of ammonia is recommended by authorities, as it destroys the formaldehyd.

Miscellany.

Clippings from Lay Exchanges.

NO CONSPIRACY ALLEGED.

"Dr. B———, of Atlantic City, is about to locate at Wycombe for the practice of his profession. The doctor has secured rooms in the home of Mrs. G——— P——— and will put up his shingle the beginning of next week. An undertaker located in Wycombe a week or so ago."—*Jenkintown (Pa.) Spirit.*

THE NEW SYMPTOM—CONSCIOUS DELIRIUM.

Under the heading: "Delirious All Evening. Members of Family were at Bedside, but He Did Not Know Them," the *Johnstown (Pa.) Democrat* says: "He was conscious to the end, but was delirious the greater part of the evening."

COLLES FRACTURE OF THE SHOULDER.

"An *x*-ray examination of the injured shoulder of W—— K——, the ball player, . . . reveals the fact that he is suffering from what is known to the medical profession as a Colles fracture."—*Norwich (Conn.) Bulletin.*

DEATH WAS NOT SURPRISING.

Under the headlines "Doctor Not Surprised at — — ———'s Death," the *Boston Morning Journal* contains these lines: "The cause of death was found to be calcification of the althe romotus tissue, just above the aortic valve."

SLICK'S FEMALE HYDRO-EMETICS.

"Dr. —— Slick of ——— has moved to ——— to practice female therapeutics, metaphysics and hydro-emetics. Dr. Slick ought to be finer than silk."—*Adrian (Mich.) Press.*

POSTMORTEM TO BE POSTMORTEM.

"The medical fraternity . . . have obtained the consent of the young woman and her parents to hold a postmortem after her death."—*Bowling Green (Ohio) Sentinel.*

THE NEW DISEASE—LAPEROTOMY.

"The patient was suffering with laperotomy and after an examination last night an immediate operation was found to be necessary."—*Muscatine (Iowa) Journal.*

Medical Courts of Honor in Prussia.—Prussia has long had a professional court of honor for the army and for law, and in 1901 a similar tribunal was established for the medical profession in every district where there is a medical organization. The court consists of the president and three members of the local organization and a judge of a local court. There is a central supreme court of appeals, consisting of the director of the Prussian ministerial medical department, four members of the central committee of the "Aerztekammer," and two physicians appointed by the crown. The penalties which the court can impose are warning, reprimand, a fine not exceeding 3,000 marks (about $750) and the temporary or permanent withdrawal of the right to membership in the local medical organization. The "Allg. Med. Ct.-Ztg." has recently been publishing the decisions of the supreme court. Its findings do not always meet with the approbation of the profession as a whole. In a recent decision, for instance, it condemned the efforts of a physician who was endeavoring to secure the introduction of the free choice of a medical attendant by the members of the sick benefit societies. This is considered by the profession a much-needed reform and is generally known as "the American plan." Among the decisions is one that imposed a fine of $50 and costs on a physician who had associated himself with a notorious magnetic healer, confirming the decree of the local court of honor. Another imposed a fine of $25 on a physician who had applied to an insurance company for a position, threatening that he would induce certain families to withdraw from the society unless he were appointed to a position in it. In one decision the supreme court reversed the action of the lower court, which had imposed a fine of $75 on a physician because he had opposed the organization of a children's ward in the city hospital, on the ground that the existing medical staff would be inadequate for the enlarged responsibilities and the

children would receive merely secondary consideration. He urged the establishment of a separate children's hospital. The charge against him was dismissed. Another physician was also acquitted who had been fined by his local court of honor. He had been called to a child with the measles, but was dismissed by the father in a few days, before the disease had terminated. He sent in his bill for his services eleven days later, and the local court of honor reprimanded and fined him. One decree states that a physician who deviates from the customs of his colleagues is not unethical so long as the deviation is not derogatory to the honor of the profession. The court of honor expressly states that its power is not limited to contemporaneous occurrences, but that all unethical acts by any living Prussian physician, since his "approbation," come within its jurisdiction. It therefore imposed a fine of $25 on a physician who had forced his professional services on a certain patient previous to the organization of the professional court. Another decision condemned as unethical "control" visits under instructions from a third party without the knowledge of the attending physician, and also derogatory remarks in regard to the professional services of any other physician in the presence of the patient. Seventeen decisions have been handed down since last May, but most of them relate to merely technical legal points.

Book Notices.

VON DER NERVENZELLE UND DER ZELLE IM ALLGEMEINEN. Von Paul Kronthal. Mit 6 chromolithographischen, 3 heliographischen Tafeln und 27 Figuren im Text. Pp. 274. Jena: G. Fischer. 1902.

When this book of nearly 300 pages, dealing with one of the most absorbing topics of the period and illustrated liberally with heliographic and chromolithographic plates, came to us we hoped much from it and, on opening it, began its perusal with a certain degree of eagerness. An appetite already keen was further whetted by a caviar which the author provides, an introductory essay on methods, in which the theories of tissue-fixation and staining are discussed. The writer's apparent familiarity with some of the more recent theories of the structure of protoplasm, including that which looks on it as essentially a colloidal solution, his acquaintance with the fundamental researches of A. Fischer concerning the effects of the fixation-agents in common employ, his references to Gierke's views on the chemistry of staining processes and to O. N. Witts' hypothesis concerning the relation of the staining to the formation of so-called "solid solutions"—all gave us the impression that our author approached his problem armed with the most modern weapons for histologic attack. There seemed every reason to believe that in a research so auspiciously undertaken, leading to results requiring nearly 300 pages for their record, and published at great cost, something of more than ordinary interest would be found. A further study of the book, however, brings disappointment.

An examination of Kronthal's monograph shows it to be divided into two parts: (1) On the biology of the nerve-cell, and (2) on the cell in general and the nerve-cell in particular. The former part includes the introductory essay on methods, a description of the figures in his plates, a review of his personal observations and the conclusions drawn from them. The latter part assumes more the nature of a philosophic treatise.

The title given to Part 1 is "The Biology of the Nerve Cell." It consists of four chapters: 1. On Methods (referred to above). 2. Description of Figures. 3. Résumé of Personal Observations. 4. Inferences Drawn from Observations. In the chapter describing the figures the author gives only a series of legends for the various figures in the colored plates. The description of the first figure is fundamental, for on this a large part of the author's other work and his inferences are based. The figure purports to be a small blood vessel from the anterior horn of a rabbit five days old, under a magnification of 500. Besides the red blood corpuscles within the lumen of the vessel there is a mononuclear cell, filling the whole lumen at its level. This cell is designated a leucocyte, though it is certainly not a polymorphonuclear leucocyte, nor a lymphocyte, nor does it resemble any large mononuclear element one ever sees in the blood. It looks more like an endothelial cell than like a leucocyte, though it is very difficult to say from the drawing what the author has seen. Outside the vessel are two nuclei without visible protoplasm. What these were drawn from is doubtful, though it seems probable that the artist really had glia cells before him. The author calls them "two bodies just like leucocytes in their internal structure and staining behavior" (*Zwei in ihrem innerem Bau und tinctoriellen Verhalten den Leukocyten ganz gleiche Koerper*). As a matter of fact, they do not look at all like his suppositious leucocyte in the adjacent blood-vessel; much less do they resemble the real leucocytes one sees in the blood. The description of this first figure is followed by those of forty other figures in the colored plates and of seven photograms.

In chapter 3, in which Kronthal gives a résumé of his observations, he states that he finds everywhere in the central nervous system, in both white and gray substances, small cells which, in their form and behavior towards staining reagents, agree with leucocytes. They are usually irregularly distributed, but are often in rows. Often no protoplasm is to be seen about them. Fusions of two or more such nuclei are often met with. Various transition stages to the large cells of the anterior horns are described. Especial stress is laid on the occasional presence of a small cell inside the protoplasm of a large cell. The author states that an examination of the good illustrations in archives and monographs reveals "the lymph cells here described in the central nervous system, their relations to one another, to the similar but larger cells, as well as to the large cells in the gray matter" entirely correctly and sharply depicted. Anatomists call the smaller cells "free nuclei" (*freie Kerne*); pathologists and psychiatrists regard the relation of the smaller cells to the larger cells as evidence of degeneration. If they had used his alcohol-glacial-acetic-fixation method, Kronthal thinks they would have seen something entirely different in these structures.

In chapter 4, Kronthal gives his own ideas as to the interpretation of the observations. He decides that he finds leucocytes all through the normal central nervous system. A great many lymphoid cells come into the nervous system from the cerebrospinal fluid. All these "leucocytes," once inside, find themselves in a totally different environment from that to which they have been accustomed. The "nomadic" cell is compelled to "settle down." Again, the wandering cell here meets with chemical substances unknown to it—cerebrin, lecithin, protagon, neurokeratin, keratin, xanthin, hypoxanthin and inosit. As a result the leucocytes lose the properties they had in the blood and take on other characters. They fuse with one another and make larger cells. Gradually the large "cells" of the gray matter are built up out of them. A nerve cell never divides, not even in the embryo. But nerve cells are present throughout life, though they are constantly degenerating. "How then," asks the author, "is the nerve-cell supply maintained?" And his answer is "in the same way that it arose originally, viz., by slightly differentiated cells coming into connection with fibers and so becoming nerve cells." Kronthal believes, then, that nerve cells differ from all other cells and that their nuclei are different from all other nuclei, for the nuclei have not arisen by mitosis, but are the result of fusion of nuclear substances of other cells. The reason there are more leucocytes in the gray matter than in the white matter is that the nerve fibers are medullated and packed together like cables in the white matter, while in the gray matter the fibers are naked; the leucocytes easily wend their way through the relatively thick cables, but are caught and held fast when they reach the extremely fine fibers of the gray matter. The nerve cells are continuously dying and continuously arising anew through the fusion of leucocytes.

The first part of the book contains all the author's observations and the inferences drawn therefrom and occupies forty pages of the volume; the second part, in which he writes a philosophical treatise on "the cell in general and the nerve cell in particular" based on the theory just outlined of the origin of nerve cells from leucocytes, occupies two hundred and twenty-two pages. It seems to the reviewer not worth the while of

American readers to be burdened with even an epitome of this part, though it has been conscientiously waded through. Kronthal introduces in the various chapters the majority of the complex names that have been given to the different parts of the protoplasm and nucleus, and most of the theories that have gradually, at one time or another, been developed in cytology; he cites references from more than 200 writers, and tries to weave all into connection with the "nerve cells derived from fused leucocytes"; he coins, unnecessarily, a certain number of new names, which add to a nomenclature already overburdened.

Kronthal's reading seems to have been encyclopedic, but he appears to be devoid of sound judgment and the power of legitimate interpretation. How his book could have secured a publisher at all, much less the imprint of the celebrated house of Gustav Fischer of Jena, is difficult for American neurologists to understand. America has more than its share of worthless publications; but a few more such volumes from Germany and she will be outrivaled. If anyone thinks the verdict here pronounced unwarranted, let him but turn to chapter xiv of the second part of the book and read Kronthal's discussion of the origin of tumors, where he develops the view that tumors arise as a result of a fertilization process, the cell of one human being, perhaps an epithelial cell or a leucocyte, entering another human being and fertilizing some cell of the host; or let him read the last two pages in the book, of which the following is a translation of the first paragraph: "The bioids in the cell are alive, the trophomigma is dead. But the bioids can not live without the trophomigma. Hence, the 'living' is the whole cell. But this again can not live, if its trophomigma is not regularly supplemented, its nutrition maintained. Hence the 'living' is the cell with its nourishment. Nourishment for the cell consists of all kinds of substances, which, for the most part, constitute the earth. So the 'living' is the whole earth, and, since this, according to the Kant-Laplace hypothesis, is a product of the same forces as is every body in space and can not exist . . . without the other bodies, so the 'living' is the whole universe. Nature is the 'living,' not this or that body." To such levels may one soar, riding on the back of a supposititious leucocyte in a spinal capillary!

Toxicology. The Nature, Effects and Detection of Poisons, with the Diagnosis and Treatment of Poisoning. By Cassius M. Riley, M.D., Professor of Chemistry and Toxicology in Barnes Medical College. Cloth. Pp. 132 Price, $1.50. St. Louis: Lewis S. Matthews & Co.

This little work is a second edition, though not so stated on the title page. It is a convenient, handy manual of the principal facts in regard to poisons and their antidotes. It is neatly gotten up and seems, in the main, to cover its subject very satisfactorily. An addition which will probably be appreciated is the series of good illustrations of some of the more important poisonous plants. One or two inaccuracies are noticed, such, for example, as the description of the poisonous serpents which is not reliable, since it only describes the viperine type. This, however, is the only type represented in this country that is really dangerous; the coral snake, which is mentioned as being comparatively rare and not vicious and hardly considered poisonous. The statement that chloroform is the principal anesthetic used in this country strikes us as incorrect. We had supposed that ether was used more at the present time for general anesthesia.

Where and How to Amputate. By Lowell E. Jepson, M.S. Paper. Pp. 13. Minneapolis: Jepson Bros.

One of the most important things to consider in making an amputation is where and how this shall be done so that the patient can with the most comfort and satisfaction wear an artificial limb. This booklet concisely states the principal points to be considered and this information will be of practical help.

Farmacoterapia con Formulario. Dr. Prassitele Piccinini. Un volume di pag. viii-382, elegantemente legato in tela. Ulrico Hoepli. Milano. (L. 3,50.)

This is one of the neat and convenient little Hoepli pocket handbooks which will be of use to those who understand Italian and almost anyone can pick up enough of that language to utilize it in a short time. The numerous formulas are easily transposed to accord with the United States pharmacopeia.

State Boards of Registration.

Missouri Examination Dates.—The regular spring examination of candidates for the practice of medicine in Missouri will be held at the University Medical College, Kansas City, Mo., April 1 to 3 instead of April 3 to 5, which was the date previously set. At St. Louis examination will be made April 13 to 15.

Confederation Meeting.—The National Confederation of State Medical Examining and Licensing Boards will hold its next meeting at New Orleans, May 4, and urges every unaffiliated state or territorial board, whose duty it is to examine or license physicians intending to practice, to affiliate with the confederation. The secretary is Dr. A. Walter Suiter, Herkimer, N. Y. An invitation is extended to physicians and educators who are interested in the cause of higher medical education to attend.

Association News.

THE NEW ORLEANS NUMBER.

A Request for Information Concerning Trains, Excursions, Etc.

The issue of The Journal of April 11 will be the New Orleans Number, and will contain the preliminary programs of each of the sections and an illustrated article descriptive of New Orleans. There will also be given railroad rates and a list of special trains, etc. All information concerning such matters should be sent us in time for publication in that issue. Special excursions have been arranged from New York, Chicago, Omaha and other points. We desire full particulars of all such trains. It is hoped that announcements may be made of the water-route excursions, one by the Mississippi River and one by the Atlantic Ocean. Any one desiring to have information on any particular point given in the New Orleans Number should write to The Journal making the request.

Stereopticon for Section on Ophthalmology.

The officers of the Section on Ophthalmology announce that Mr. Earl J. Brown has offered his services and the use of the Geneva Optical Co.'s stereopticon, with or without microscopic adjustment, for the use of such members of the Section on Ophthalmology as desire to have their papers illustrated thereby.

ACCOMMODATIONS AT NEW ORLEANS.

Important Announcement from the Hotel Committee.

We are in receipt of a letter from Dr. E. D. Martin, 810 Common street, New Orleans, chairman of the Hotel Committee, asking us to publish a notice and urge on those who expect to attend the New Orleans meeting the importance of writing him at once regarding reservation of rooms. This is of special interest to those who will be accompanied by ladies. He states that New Orleans is amply able to give comfortable accommodations to all at reasonable rates, although the space in some of the hotels will be taken up early. Those having the responsibility of this matter in New Orleans desire to emphasize the necessity of early action so that all may be accommodated, and that without any complications, on arrival.

Dr. Martin closes by saying: "The Information Bureau has a list of houses that we have visited and inspected and can vouch for, of over three thousand rooms, and there is no alarm necessary, as every one will be cared for at reasonable prices."

The New Orleans illustrated number of The Journal will be issued April 11, giving a full description of New Orleans and its accommodations.

NATIONAL BUREAU OF MEDICINES AND FOODS.

The President of the American Medical Association has appointed the following as a committee to represent the Association to investigate the proposed National Bureau of Medicines and Foods, this committee to report at the New Orleans meeting: Dr. E. Eliot Harris, New York; Dr. Solomon Solis-Cohen, Pennsylvania; Dr. H. Bert Ellis, California; Dr. N. S. Davis, Jr., Illinois; Dr. Philip Mills Jones, California.

Societies.

COMING MEETINGS.

AMERICAN MEDICAL ASSOCIATION, FIFTY-FOURTH ANNUAL MEETING, NEW ORLEANS, MAY 5-8.

New Mexico Medical Society, E. Las Vegas, April 7.
Florida Medical Association, St. Augustine, April 8.
Western Ophthalmological and Oto-Laryngological Association, Indianapolis, April 9-11.
Tennessee State Medical Society, Nashville, April 14-16.
Medical Association of Georgia, Columbus, April 15.
South Carolina Medical Association, Sumter, April 15-16.
Iowa State Medical Society, Sioux City, April 15-17.
Medical Association of the State of Alabama, Talladega, April 21.
Medical Society of the State of California, Santa Barbara, April 21.
Mississippi State Medical Association, Greenville, April 21-23.
Medical Association of the State of Missouri, Excelsior Springs, April 21-23.
Kentucky State Medical Society, Louisville, April 22-24, 1903.
Texas State Medical Association, San Antonio, April 28.
Louisiana State Medical Society, New Orleans, April 28-30.
Medical and Chirurgical Faculty of Maryland, Baltimore, April 28-30.
Nebraska State Medical Society, Lincoln, April 28-30.
Illinois State Medical Society, Chicago, April 29-May 2.
Arkansas Medical Society, Jonesboro, April 30-May 2.

Kentucky State Medical Association.—The forty-eighth annual meeting will be held in Scottish Rite Temple, Louisville, April 22, 23 and 24.

Polk County (Iowa) Medical Society.—At its March 3 meeting this society decided so to change its by-laws as to admit any non-sectarian practitioner of medicine.

Medical Woman's Club of Chicago.—This club was recently organized, with Dr. Sarah Hackett Stevenson as president, and Dr. Henrietta Johnston, secretary and treasurer.

Sangamon County (Ill.) Medical Society.—At its monthly meeting, March 9, the constitution and by-laws of the society were amended to conform to those of the Illinois State Medical Society.

Hamilton County (Neb.) Medical Society.—The physicians of Hamilton County recently met at Aurora and organized a county society, with Dr. Edmund A. Steenburg president and Dr. Isaiah W. Haughey secretary, both of Aurora.

Louisville Practitioners' Club.—The annual meeting and banquet was held March 10. Dr. Oscar E. Bloch was elected president; Dr. Hugh N. Leavell, vice-president; Dr. John J. Moren, secretary and treasurer, and Dr. John K. Freeman, historian.

Vernon Parish (La.) Medical Society.—This society was organized at Leesville, March 4, with Dr. Mark R. McAlpin, Leesville, president; Dr. C. C. Self, Hornbeck, vice-president; Dr. F. W. Dortch, Barham, secretary, and Dr. J. H. Word, Leesville, treasurer.

Holt County (Neb.) Medical Society.—The physicians of Holt County recently met at Atkinson and organized a county society, with Dr. Joseph L. McDonald, president; Dr. B. T. Trueblood, O'Neill, vice-president, and Dr. P. J. Flynn, O'Neill, secretary and treasurer.

Steele County (Minn.) Medical Society.—At the annual meeting, March 10, the following officers were elected: President, Dr. George Shulze; vice-president, Dr. John H. Adair; secretary, Dr. Allan B. Stewart, and treasurer, Dr. Warren C. Eustis, all of Owatonna.

Johnson County (Texas) Medical Society.—At the March 13 meeting, at Cleburne, the following officers were elected: President, Dr. W. P. Alexander, Cleburne; vice-presidents, Drs. Larkin L. Harris, Cuba, and R. H. Roark, Cleburne, and secretary, Dr John M. Huddleston, Cleburne.

Philadelphia Society of Tropical Medicine.—This society, whose object is the study of tropical diseases, has been formed, with the following officers: President, Dr. Thomas H. Fenton; vice-presidents, Drs. James C. Wilson and James M Anders; secretary, Dr. Joseph McFarland; treasurer, Dr. Edward B. Gleason, and executive committee, Drs. John V. Shoemaker, James Fenton, Judson Daland, Roland G. Curtin, Orville Horwitz and Hobart A. Hare.

Mercer County (Ohio) Medical Society.—On March 10, with the assistance of Dr. Horace Bonner of Dayton, Ohio, councillor for that district, the Mercer County Medical Society was reorganized at Celina, Ohio, in affiliation with the Ohio State Medical Association. These officers were elected: Dr. D. J. C. Wintermute, Celina, president; Dr. C. F. Bohnan, Coldwater, vice-president; Dr. D Herbert, Richardson, Celina, secretary; Dr. J. E Hattery, Celina, treasurer, and Drs. Joseph Sager and Stephen R. Wilson, Celina, and Philip F. Weamer, Coldwater, censors.

Erie County (N. Y.) Medical Association.—At the annual meeting, March 9, the resolutions prepared by Drs. Julius Ullman, De Lancey Rochester and Charles S. Jewett, the committee of public health, were unanimously adopted. They state that, because of an epidemic of typhoid fever at West Seneca, and because the drainage therefrom into Lake Erie is close to the intake of the water supply of Buffalo, that Buffalo's water supply is now a menace to the public health and that the authorities of West Seneca, Buffalo and New York state should take immediate action. Officers for the ensuing year were elected, as follows: President, Dr. Allen A. Jones; vice-president, Dr Carlton C. Frederick; secretary, Dr. Jacob S. Otto; treasurer, Dr. William I. T. Lornton, and member of executive committee, Dr. Joseph W. Grosvenor.

NEW YORK COUNTY MEDICAL ASSOCIATION.

Stated Meeting, Dec. 15, 1902.

The President, Alexander Lambert, M.D., in the Chair.

The Rational Treatment of Tetanus.

DR. WILLIAM H. LUCKETT made a brief report covering his experience in three cases successfully treated by intraspinal injections of tetanus antitoxin. One case received eight injections of from 8 to 15 c.c., or a total of 92 c.c., 159 minims of cerebrospinal fluid being withdrawn. Another case received five injections, a total of 59 c.c., and 532 minims of cerebrospinal fluid were withdrawn.

Modern Treatment of Urethral Stricture—Dilatation.

DR. J. W. S. GOULEY opened the symposium on the modern treatment of urethral strictures with a paper on their treatment by dilatation, laying down the following propositions: 1, Strictures at the meatus, being ordinarily dense, require incision; 2, strictures in the scrotal region which are narrow, indurated, resilient and refractory to treatment require internal incision; 3, strictures which render catheterism difficult or dangerous ordinarily require internal incision if in the scrotal region, and external incision if in the perineal region; 4, strictures in the perineal region which are narrow and complicated with fistulæ, and accompanied by masses, require external incision; 5, strictures in the perineal region complicated by abscess or extravasation of urine require immediate external incision; 6, traumatic strictures in the perineal region require early external incision, and 7, other urethral strictures are generally amenable to dilatation, or, at least, divulsion. In the early stages of strictures due to urethritis a permanent cure could be effected in a few months by simple dilatation, but in the long-standing ones months or even years of dilatation would be required. Continuous dilatation or the retention of an instrument for a few hours or even for one or two days, was indicated in narrow strictures, which failed to yield to ordinary dilatation or were complicated by retention of urine. Rapid dilatation, or the increase of the caliber of the urethra by three or four numbers at a sitting, was indicated in narrow strictures which threatened to produce retention of urine.

Urethrotomy.

"Internal Urethrotomy" was discussed by DR. L. W. HOTCHKISS, and "External Perineal Urethrotomy" by DR. PARKER SYMS. These two papers were given in abstract in THE JOURNAL, February 28, p. 608, ¶78 and ¶79.

Discussion.

DR. JOSEPH D. BRYANT said he had always been averse to very free division of the meatus urinarius. Continuous dilatation was a useful method, if proper judgment were exercised as to the length of time it is to kept up.

DR. JOHN F. ERDMANN spoke in favor of the Oberlander and Kollmann dilating instruments, and recommended dilating to the extent of from 2 to 4 mm. at each sitting, the treatment being repeated at intervals of four or five days. The continuous method was, no doubt, a useful one, but in many

of the cases in which it had seemed to be indicated he had succeeded by giving the patient a warm bath for fifteen to thirty minutes. In performing external urethrotomy without a guide he preferred to do the operation as advised by Dr. Bolton. In this method, the patient is placed in the reversed Trendelenburg posture, and an incision is made from one tuberosity of the ischium to the other in the form of an arc. This gives ready access to the apex of the prostate and, when this is found, puncture is made and then a dissection is made towards the membranous portion of the urethra. So far, this method had been invariably successful.

DR. E. L. KEYES, JR., said that it was certainly desirable to have a large incision, but the one recommended by the last speaker appeared to him to be an unnecessarily free dissection. If the dissection were carried down to the face of the stricture it would be comparatively easy to find the opening of the latter.

DR. FERD C. VALENTINE expressed himself as strongly in favor of the treatment of urethral strictures by dilatation, as opposed to operative measures, and condemned the too common plan of leaving this dilatation treatment to the patient himself.

DR. WILLIAM A. SHUFELT spoke in favor of an early resort to perineal section rather than indulging in much experimentation.

DR. ROBERT NEWMAN said that up to seven years ago he had successfully treated by electrolysis over 2,000 strictures of the urethra, and that number was now increased by probably 400 or 500. Relapses never took place, a statement regarding the permanency of the cure effected by this method of treatment which could be substantiated by patients in this city who had remained well for long periods of time—even as long as 26 years. This treatment by electrolysis of urethral strictures had been the subject of an investigation by a committee of his peers appointed by the American Electrotherapeutic Association in 1892. This committee, after long and careful investigation, reported that Dr. Newman's conclusions appeared to be well sustained by the statistics placed at its disposal, and that the experience of the committee also tended to confirm the value of the continuous current in resolving a large class of urethral strictures. The trouble with internal urethrotomy was that it would not restore the caliber of the urethra if the incisions healed by first intention, and if these incisions were kept apart and were made to fill up by granulation, a cicatrix would be formed, which would make the last state worse than the first. It was worthy of note that many authorities had in recent years declared themselves as opposed to internal urethrotomy.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and. in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Symposium on Colic.—I. In Infants.

Dr. Robert Hutchison, in *The Clin. Jour.*, states that the chief symptom of infantile colic is pain, expressed by crying. However, the cries of the infant should cause one to consider the possibility of earache, teething, renal colic (which is as frequent as in older people), phimosis causing straining on passing water and tenderness of the bones resulting from rickets, congenital specific disease, also mental deficiency causes the infant to cry without apparent cause. The signs of colic are: hardness of the abdomen, palpation of little coils of intestine, the tendency of the infant to draw up the legs, and perhaps convulsions. The passage of flatus with cessation of crying is a splendid sign of the proper diagnosis.

The first thing in the treatment is to apply warmth to the abdomen. This can be done by friction with warm oil, by warm fomentations or by poultices of linseed or mustard, and if necessary by the mustard bath. Warmth may be employed internally by means of enemas of hot water, injecting two or three ounces of water as hot as can be borne. Carminatives by the mouth, according to the author, aid in the expulsion of flatus, as peppermint water or dill water or small doses (ten drops) of sweet spirits of niter.

CORRECTION OF FEEDING AND OF CONSTIPATION.

If the infant is breast-fed inquiry may show that it is being fed irregularly and too frequently. Constipation must also be corrected. Massage to the abdomen is indicated in such cases following the course of the colon, applying it morning and evening for five or ten minutes. As to the medicines to be administered, they should consist of such preparations as have a tonic action on the bowel such as aloes combined with a little nux vomica as follows:

℞.	Tinct. aloes	gtt. iii-v	20-.30
	Tinct. nucis vom.	gtt. ss	03
	Tinct. belladonnæ	gtt. ii	12
	Syr. sennæ	gtt. xx	1 30
	Inf. gent. co. q. s. ad	3i	4

M. Sig.: To be taken at one dose night and morning or in severe cases once in six hours.

The foregoing should be varied according to the age, remembering that children bear belladonna very well and strychnia badly. In case children should object to this mixture or are unable to retain it on the stomach the following may be given:

℞.	Confectionis sulphuris	℥ss	15

Sig.: One half teaspoonful at night or morning and night.

This is very agreeable for infants to take, but not so effective as the first combination.

In bottle-fed infants the frequent cause of colic is lack of cleanliness. The feedings are also given irregularly, and the food probably indigestible, owing to excess of casein products. In any case carminatives frequently give relief when given between meals. It should be alkaline on account of the extreme acidity present in the stomach and should be pleasant to take. The following combination serves the purpose:

℞.	Sodii bicarb.	gr. iiss	15
	Spts. ammon. arom.	m. iiss	15
	Glycerini	m. ii	12
	Aq. menth. pip. q. s. ad	3i	4

M. Sig.: At one dose, to be given between the feedings.

In all such cases the abdomen must be kept warm. Binders should be used, if necessary, and the feet should be well protected.

If the child is gaining weight, even though there are attacks of colic, no great alteration in the food should be made. Some preparation of opium may be administered as follows:

℞.	Codeinæ	gr. 1/40 to 1/30	0015-.0020
	Glycerini	m. ii	03
	Aq. menth. pip. q. s. ad	3i	4

M. Sig.: At one dose to relieve the colic.

If acute vomiting is present the infant should be starved for two, three or more days, if necessary. During this period water (boiled) must be given in abundance.

VOMITING.

Lavage is of great service in cases of acute or chronic vomiting. It is not so unpleasant as in adults, and is simple and harmless. If the eyelet of the tube becomes clogged with clots of casein they may be dislodged by blowing into the top of the funnel. If the contents of the stomach are sour sodium bicarbonate should be added to the water in proportion of one teaspoonful to the pint.

Calomel is one of the best medicinal preparations, given in doses of one-tenth grain (.006) to one-sixth grain (.01) every hour for six or seven doses. This may be followed by bismuth subnitrate or the carbonate in ten-grain (.6) doses.

In chronic vomiting the feedings should be diluted and regulated and the stomach washed out before resorting to drugs. Bismuth is the best, given in large doses. In other cases two or three minims of dilute hydrochloric acid is of service, combined as follows:

℞.	Acidi hydrochlor. dil.	m. ii-iii	12-.20
	Glycerini	m. ii	12
	Aq menth. veridis q. s. ad	3i	4

M. Sig.: At one dose.

ACID FERMENTATION.

When the contents of the intestine are undergoing acid fermentation causing colic, the following antacid aperient has been recommended:

℞.	Pulv. rhei comp.	3i	4
	Spts. ammoniæ fœtidi	3ss	2
	Tinct. card. comp.	3iii	12
	Spts. chloroformi	3ss	2
	Aquæ carui q. s. ad	℥iss	45

M. Ft. mistura. Sig.: One or two teaspoonfuls, according to the age of the child, every hour until relieved.

Yeo recommends the following as a clyster when there is difficulty in getting the child to take medicine by the mouth:

℞.	Olei ricini	3i-3iii	4.-12	
	Olei rutæ	mii-vi		12-.35
	Potassii carb.	gr. v-xv		30-1.00
	Aquæ q. s. ad	℥ii-iv	60-120	

M. As a high enema. If, after free evacuation of the bowels, there is still pain and distress the following may be given as an enema:

℞.	Tinct. opii	m. i-ii	06-.12
	Emuls. amyli	℥i-℥ii	30-60

M. Sig.: As an enema in case the child is over six months of age; or:

℞.	Tinct. cascarillæ		
	Tinct. krameriæ, āā	m. x	65
	Olei anthemidis	m. i-ii	06-.12
	Syr. simplicis	3iiss	10
	Aq. q. s. ad	℥ii	60

M. Sig.: One teaspoonful every two hours by the mouth.

II. Colic in Adults.

Yeo, in his *Clin. Ther.*, recommends, in the treatment of colic in adults, the administration of one to two pints of warm soapsuds, containing one or two tablespoonfuls of castor oil and in flatulent distention a tablespoonful of spirits of turpentine. Locally, he recommends hot flannels or a linseed poultice sprinkled with laudanum applied to the abdomen. The surface of the abdomen may be rubbed with opium or belladonna liniment, employing massage at the same time. If the trouble be confined to the small intestine a mild cathartic such as castor oil or calomel should be given by the mouth. In severe cases a hypodermic of morphin may be given. Atropin relieves intestinal spasm by relieving the irritability of the intestinal nerves and does not have so ill an effect on the intestinal nerves as has opium. The following combination is recommended by the author:

℞.	Tinct. belladonnæ	3ss	2
	Tinct. card. comp.		
	Spts. ammon. arom.		
	Spts. chloroformi, āā	3ii	8
	Sodii bicarb.	3i	4
	Aquæ fœniculi q. s. ad	℥vi	180

M. Ft. mistura. Sig.: Two tablespoonfuls every hour until relieved.

In gouty individuals accompanied by constipation warm alkaline medicines are recommended:

℞.	Ammon. carb.	gr. xl	2	65
	Sodii bicarb.	gr. lxxx	5	
	Spts. chloroformi	3iii	12	
	Tinct. zingiberis	3i	4	
	Aquæ cinnamomi q. s. ad	℥viii	240	

M. Ft. mistura. Sig.: Two tablespoonfuls combined with one of hot water every three or four hours.

As a pill to be taken at bedtime in these gouty cases, the following:

℞.	Ext. colchici	gr. ss	03
	Pil. rhei comp.	gr. iv	25

M. Ft. pilula No. i. Sig.: One such to be taken every night.

FLATULENCE.

The following combination is of service in checking decomposition:

℞.	Ext. nucis vom.	gr. iss	09
	Argenti nitratis	gr. ii	12
	Ext. lupuli	gr. xii	75

M. Ft. pil. No. vi. Sig.: One pill three times a day; or:

℞.	Mag. carb.	3i	4	
	Pulv. rhei	3ss	2	
	Tinct. rhei	3iii	12	
	Tinct. opii	m. xv	1	
	Spts. anisi	m. vi		35
	Spts. menth. pip.	3ii	8	
	Aq. destil.	℥vi	180	

M. Sig.: Shake. One tablespoonful three times a day; or:

℞.	Spts. chloroformi		
	Tinct. cardamom. co., āā	℥i	30

M. Sig.: One teaspoonful in water every half hour; or:

℞.	Olei cajuputi	m. iv		25
	Sacch. albi	gr. x		65
	Tinct. jalapæ	3i	4	
	Decoct. aloes comp. q. s. ad	℥iss	45	

M. Sig.: At one dose; or:

℞.	Spts. chloroformi	3i	4	
	Morph. acetatis	gr. iss		09
	Olei anisi	m. viii		50
	Olei menth. pip.	m. viii		50
	Syr. acaciæ	3ii	8	
	Aq. camphoræ q. s. ad	℥ii	60	

M. Sig.: One teaspoonful at a dose and repeat in an hour if necessary.

The *Ther. Gazette* recommends the following to relieve the flatulent colic in women:

℞.	Spts. ammon. arom.	3iss	6
	Tinct. belladonnæ	3ss	2
	Tinct. zingiberis	3i	4
	Spts. chloroformi	3i	4
	Aq. menth. viridis q. s. ad	℥vi	180

M. Sig.: One tablespoonful every two hours if necessary.

Infant Feeding.

Prof. Rotch, in a recent address before the medical students of Chicago, emphasized the importance attached to accurate knowledge of preparing food for the infant and the ability to write a proper prescription whereby it may be prepared in the laboratory. He dwelt on the fact that infants thriving on the mother's milk containing a definite amount of proteids could not be placed on artificial food containing the same amount of proteids obtained from the cow's milk. The casinogen in the proteids of cow's milk seems to be the disturbing factor, thus producing the curds present in the stools, rather than the whey proteids. According to the author the casinogen should be reduced to a minimum to begin with and make up the necessary per cent. of proteids from the whey proteids. By overlooking the presence of the casinogen we fail in our efforts, where otherwise success might be obtained. That physician, according to Prof. Rotch, is not versed in the modern methods of percentage feeding who resorts to the use of the cereal products, otherwise starch, in combination with the milk in order to reduce the curds in the stools. The presence of starch more finely divides the curds and does not reduce their quantity. When sugar is deficient in the food he also insists on making up the deficiency by adding milk sugar (lactose) and not cane sugar as recommended by some authors. He, however, favors the mother's milk if it is borne by the infant to any moderate degree rather than to resort to artificial feeding.

Medicolegal.

Test of Nature of Incorporated Hospital Association.—In the case of Craig vs. the Benedictine Sisters' Hospital Association, the Supreme Court of Minnesota follows the rule that the nature and character of a corporation must be determined from its articles of association, and that its character can not be changed or modified by oral evidence that it is not in fact such a corporation as its articles purport to make it; that, in determining the character of corporations, the articles of association are the sole guide. In this case, the association was incorporated under the provision for the formation of corporations for a pecuniary profit, and, on the face of its articles of association, appeared to be an ordinary business corporation. The court holds that evidence offered for the

purpose of showing that it was in fact a charitable association, and not what its articles purported to make it, was incompetent and inadmissible. Whether a corporation organized for purely charitable purposes, and dependent on voluntary contributions for its support, is liable in damages for the negligence of its officers and servants, the court leaves an open question, so far as it is concerned.

Contract of Physician with Voluntary Association.—In the case of McDermott vs. the St. Wilhelmina Benevolent Aid Society, an action brought by a physician against the individual members of the society, a voluntary association, to recover for professional services, the Supreme Court of Rhode Island holds that, notwithstanding the association was a voluntary one and the physician did not receive a majority of the votes cast, nevertheless he was elected the physician of the association, and the individual members thereof were bound by the contract entered into with him. It appeared that he did receive more votes than any other candidate; that the president declared him elected, and directed the secretary to notify him of his election, to which proceedings no objection was made. Under these circumstances, the court does not think that the irregularity mentioned could properly be held to render the action void. It says that it was merely a technical violation of the rule, and it was doubtless competent for the society, if it saw fit, to dispense with the formality of taking a second vote. Moreover, by allowing the president to declare the physician elected as the physician of the association without dissent on the part of any one present, his election was practically made unanimous. Besides, the court holds that, after the association had recognized the fact that the physician was occupying the position to which he had thus been chosen by directing the secretary to notify him of his discharge therefrom and subsequently choosing another "for the balance of the present term," the technical irregularity stated could not be set up as a defense to his right of recovery for services rendered. It is a matter of common knowledge, the court says, that both corporations and voluntary associations often disregard, to some extent, the strict rules of procedure prescribed in their charters or by-laws in transacting their internal affairs; but, so far as this court is aware, the courts have not held that such technical variation from prescribed forms relieved them from liability to outside parties doing business with them in good faith on the strength of what appeared by their own records to have been regularly and properly done. Of course, the court says, no authorities need be cited to support the physician's claim that the contract with the association was consummated on his depositing his acceptance thereof in the mail, the acceptance having been made within a reasonable time after notice of the election. As to members of the association who were not present when the election took place, the court says that the presumption is that each person, on becoming a member of an association of this sort, knows and consents to be governed by the rules thereof; and hence whatever action is properly taken thereunder by the association is as binding on those members who were absent at the time it was taken as on those who were present. This individual liability arises, not on the ground that the members of such an association are partners, for they are not, but on the ground that the society is their agent in the premises; and hence they are bound by its acts if done within the scope of its authority. No compensation having been expressly fixed on by the association at the time of the election, and it appearing that the physician had previously served them on certain terms, the court holds that the presumption was, in the absence of any statement or agreement to the contrary, that his compensation would be the same as that previously paid. And it thinks pertinent instructions in which the jury were told that when one enters into the service of another for a definite period, and continues in the employment after the expiration of that period without any new contract, the presumption is that the employment is continued on the terms of the original contract. An express request from the parties sued to the physician to render services for them implied an agreement on their part to pay him what his services were reasonably worth.

1 *Tropical Diseases—Eight Lectures in a Course on Tropical Diseases. Charles F. Kieffer.
2 Occlusion of the Superior Temporal Artery of the Retina in a Young Anemic Girl. G. E. de Schweinitz.
3 *Collective Investigation Concerning the Value of Silver-Nitrate Injections in the Treatment of Pulmonary Consumption. Thomas J. Mays.
4 *Some Points in the Management of Infectious Diseases. A. G. Young.
5 *The Treatment of Tropical Dysentery with Sulphur. T. H. Weisenburg.

1. **Tropical Diseases.**—The eighth lecture of Kieffer deals with the subject of filariasis. Of the various species of filariæ there are only two inhabiting the blood that have a pathologic importance. They are the *Filaria nocturna*, formerly called *Filaria sanguinis hominis*, and the *Filaria perstans*. The former is the cause of the well-known condition known as elephantiasis. It is found in almost all tropical and subtropical countries, as far north as Charleston, S. C. In the large majority of cases it causes no symptoms, but in exceptional instances the conditions known as elephantiasis, chyluria, etc., are produced. They may be divided into two classes, those which are due to lymph varices and those due to edema or lymphatic obstruction. The worms may block the thoracic duct or they may injure some special portions of the lymphatic system and produce elephantiasis. He describes the different conditions and remarks briefly in regard to *Filaria perstans* which is supposed by Manson to cause the Congo sleeping sickness which has become so severe a scourge in some parts of East Africa. There still remains a group of filariæ that invade the connective tissues rather than the lymph and the blood stream, the Guinea worm, the eye worm, and one or two others. Only the first of these is of special interest, as it may produce serious abscess and even death. The invasion of all forms of filaria is usually through drinking water, at least that is presumed to be the case.

3. **Silver Nitrate Injections in Tuberculosis.**—Mays has experimented with silver nitrate injections in the treatment of pulmonary consumption in fifty-two cases, with the result of arresting eleven and improving twenty-two, while seven were not improved and five died. There was a marked gain in weight in a large proportion of cases. Cough was relieved, which, he thinks, is due to stimulation of the vagus, increasing its resistance. Vomiting and night sweats were also notably relieved. He says:

> Taking a general survey of the above collection of cases, and the therapeutic results which have been obtained through them, I think it is plainly evident that the silver nitrate injections possess a decided antagonism to the pathological and complex process which we known as pulmonary consumption. It must be borne in mind, however, that in forming an estimate of the action of a new remedy it is comparatively easy to overrate its virtues and to ignore the efficacy of other influences that enhance its final effects. But, making due allowance for all such weaknesses, we have in this collection a confirmation of the results which were obtained by myself with the silver injections employed in a large number of cases more than four years ago, differing from mine in the fact that they are more forcible, because they emanate from a number of independent observers in whom the personal equation was entirely eliminated. In conclusion, I trust that this research into the clinical action of silver nitrate in the treatment of phthisis will merely be an entering wedge into this inviting field of therapeutics and will induce many others to take up the work and develop its possibilities.

The directions for giving the injections are as follows:

> Select for injection a point immediately over, or slightly behind, the pulsating carotid artery in the neck, between the angle of the jaw and the clavicle. Lift the skin between the thumb and forefinger of the left hand and puncture only immediately through the skin. Inject five minims of a 2½ per cent. solution of cocaine hydrochlorate, detach the syringe from the needle and let the latter remain in the puncture. Wash out the syringe with water, draw a 2½ per cent. solution of silver nitrate into the syringe, attach the latter to the needle and throw in 5 minims of same. Or, if cocaine nitrate can be secured, mix 6 grs. of this and 6 grs. of silver nitrate with half an ounce of water and inject 10 minims. This is a preferable method, but as yet there is very little cocaine nitrate on the market. As a rule, most of the injections should be given on the side below which the affected lung is located.

4. **Infectious Diseases.**—Young's article points out the various disorders which should be subject to notification and

isolation, including under this head tuberculosis, diphtheria, scarlet fever, typhoid fever, smallpox, pneumonia, grippe, whooping cough and measles.

5. **Tropical Dysentery.**—The results of treatment simply by the use of sulphur water of a special spring in the island of Marinduque, P. I., in cases of tropical amebic dysentery are reported by Weisenburg. The acute cases were kept quiet and simply put on a milk diet and made to drink the sulphur water of the spring exclusively and bathe in it every morning. The chronic cases were allowed to take moderate exercise, a soft diet, and take a bath twice daily and drink the sulphur water. In both classes improvement was marked. The patients gained in weight and strength and in three to six weeks were pronounced cured. A notable fact also was that dhobie itch, the prevalent skin malady of the tropics, was also cured by the same treatment. The spring is a large one and has long had a local reputation throughout the islands. Its water can be purchased in the drug stores in Manila.

Medical Record, New York.

March 14.

6 *Some Observations on Vulvovaginitis in Children (with Special Reference to the Gonorrheal Form); Its Treatment and Possible Sequelæ. Samuel W. Bandler.
7 *Clinical Notes on a Series of Nine Consecutive Cases of Ectopic Gestation. Hiram N. Vineberg.
8 *Mosquitoes, Quarantine, and Some Statistics with Regard to Yellow Fever. Quitman Kohnke.
9 *The Indications for Opening the Pars Mastoidea. L. D. Brose.
10 *Hot Decinormal Salt Solution Injections in the Treatment of Hemorrhoids. Lucien Lofton.

6. **Vulvovaginitis in Children.**—Bandler's article deals especially with the gonorrheal form, though he admits that there may be a coccal vulvovaginitis not gonococcal. The most important sequelæ in the way of permanent injury is atresia of the hymen or of the vagina, and a considerable portion of his paper is devoted to this subject. All the lesions of the adult, however, may be reproduced in children.

7. **Ectopic Gestation.**—The nine cases reported by Vineberg are of interest as illustrating special points in the occurrence of this condition. In the first there was no delayed or irregular menstruation and the diagnosis of ovarian disease was a perfectly natural one. The second was a typical case. Others were complicated, with menstrual irregularities in the normal condition, which obscured the diagnosis. Others gave symptoms of early miscarriage. In still another an attack of acute appendicitis was thought probable. In all but two there was more or less elevation of temperature. In two cases it reached 102.6 and in one 103.8. It has been generally thought that absence of fever in ectopic pregnancy is an important diagnostic point, but these cases disprove this as an invariable rule.

8. **Yellow Fever.**—Kohnke takes issue with Souchon in regard to questions of quarantine in yellow fever, holding that the mosquito theory is absolutely correct and that the sulphur disinfection of vessels for the destruction of the mosquito is a matter which is being neglected under present rules in New Orleans.

9. **Mastoid Operations.**—Brose reports a case and notes the special indications for operation on the mastoid, such as pain, fever, pressure, tenderness, percussion dullness which is uncertain and should be sought for, swelling and edema, swelling of the posterior superior bony meatus wall giving rise to narrowing or total occlusion of the meatus, fluctuation in the external swelling, which should be sought for earlier in children than in the adult. With such symptoms, if persistent eight or ten days without improvement in spite of treatment, or when they have wholly disappeared, either with or without closure of the drum perforation, and again returned in severity and persistency, mastoid operation may properly be performed. Chronic disease of the mastoid may exist for years without sufficient evidence to warrant operative interference, but there is always danger of serious complications. Operative interference is urged for those that can not be otherwise relieved. As symptomatic of pus retention, we have a sudden diminution or total cessation of a profuse ear discharge, narrowing of the meatus or clogging of the tympanic cavity by granulations or polypi, fever and symptoms of meningeal irritation. External abscess formation, with fistulous opening, leading into the middle ear or mastoid, in the adult especially, indicates operation. In children, however, drainage is good, nature may bring about a cure when assisted by local treatment. Cholesteatoma in the temporal bone may also require removal through a mastoid operation. The case reported illustrates a fatal termination following caries with acute mastoiditis. A large part of his paper is given up to the pathology of the condition and the special symptoms.

10. **Hemorrhoids.**—Lofton has employed hot decinormal saline solution injections in the treatment of piles with success in seventeen cases. The hot water burns the flesh, producing a simple scalding process which acts as does an escharotic, hence, a sloughing process must follow, resulting finally in elimination followed by granulation and a cicatrix. Owing to the great heat incorporated in this method, the albumin of the blood is immediately coagulated, and thus we have a circumscribed area of tissue walled off. The method, he says, is simple, cheap, effective, non-toxic and always safe. Boiling water thus used seems to act, in a measure, as a local anesthetic.

11. **Obstinate Subacute Rheumatism.**—The failure of the salicylates in certain cases is first noticed by Walsh. He calls attention to the fact that a number of cases disagree with the general consensus of opinion in regard to the salicylates being the best remedies for rheumatic disorders. Among the conditions which may cause confusion and be erroneously treated with these drugs he enumerates gout, which he thinks is less infrequent in this country than has been supposed, certain nervous disorders, neuritis, alcohol and lead poisoning, and the joint affections of scurvy and hemophilia, influenzal and dysenteric joint symptoms, bronchiectatic and other joint disorders. He says that most of the cases of obstinate subacute rheumatism are not simple rheumatic arthritis, but consist of the joint affection developing in the presence of a diathesis, such as gout, or some blood dyscrasia, or some toxemia, or a neurosis, or a hypersensitive condition of the vasomotor system, all of which hinder the normal reaction and prevent the prompt relief of symptoms that usually occurs.

12. **Transplantation of Tumors.**—In a former article in the *Journal of Medical Research*, abstracted in THE JOURNAL, xxxix, 113, p. 399, Loeb reported the results of transplantation of sarcoma and mixed tumors. In the present communication he discusses the resisting powers of excised pieces of tumors and the influence of temperature, of preservatives, such as glycerin and potassium cyanid. He also speaks of the influence of bacterial products on the growth of transplanted pieces of tumors, the injection of tumor juice, the injection of filtrates of tumor tissue in sodium chlorid solution and, lastly, the injection of hyaline bodies to be found in pieces of tumors kept outside of the body. The conclusions to which the experiments seem to lead are given by him as follows:

A micro-organism living outside of tumor cells and passing through the pores of the Berkefeld filter is not, in all probability, the cause of the formation of sarcoma in rats.

A micro-organism living outside of tumor cells and resembling organisms like the tubercle bacillus, or belonging to the class of blastomycetes, is probably not the cause of the formation of sarcoma. Such a micro-organism would probably not be made absolutely ineffective by heating to 45 C. for half an hour. A microscopic examination of tumors not secondarily infected does not show any bacteria or blastomycetes. No giant cells characteristic of granulomas caused by the tubercle bacillus or by the blasomycetes can be found in these sarcomas.

The following possibilities remain: The formation of sarcoma is caused by an organism living outside the tumor cells, possessing,

however, a similar sensitiveness to heat as do the tumor cells themselves. Such organisms would have to be, as we may conclude from the foregoing experiments, larger than red blood corpuscles, as they seem to be unable to pass, at least under ordinary circumstances, through filter paper.

But, since a careful microscopic examination of the tumors showed no structures other than tumor cells and their products of degeneration, and since, also, injection of the hyaline bodies referred to had negative results, the existence of such organisms would seem to be improbable. Still, further experiments ought to be made before these can, with certainty, be excluded.

The remaining possibilities are that a very small micro-organism not capable of living outside of tumor cells is present; and, lastly, that a micro-organism is not the cause of tumor formation. It would, therefore, be impossible to produce tumors by the injection of micro-organisms alone, if a micro-organism incapable of living outside of tumor cells is present or if no micro-organism is the cause of tumor formation.

He adds some further results, stating that there is no appreciable period of latency in the growth of the peripheral transplanted tumor cells, that the serial sections have shown that apparently separate tumor nodules of sarcoma may be connected by rows of cells, just as Petersen showed the connection of apparently separated carcinomatous cell nests, and also that active mitotic cell proliferation takes place in tumor nodules. Sarcomatous cells are phagocytic and may take up extravasated blood corpuscles. The transplantation of sarcoma was even more frequently successful than that of carcinoma. He finds the results of transplantation of tumor cells as compared with that of ordinary tissue, seem to conclusively show that mere displacement of adult tissue, if it plays any part at all in tumor production, which is not probable, is certainly unessential. The fact that non-infected fresh pieces of sarcoma may be successfully transplanted into the majority of animals of the same species, shows that a predisposition is not the main factor which prevents or favors metastases. The transplantation of tumor cells through so many generations would seem to prove that the life of ordinary tissue may, under conditions not realized in one organism, be able to continue much longer than the individual to which they belong.

13. **Fibroma of the Ovary.**—Erck reports a case which he remarks is of interest from the standpoint of the association of ascites with solid ovarian growths. In fibroma of the uterus such complication is rare, while it is common in fibroma of the ovary. He thinks that, possibly, ascites may be due to something intrinsic in ovarian growths, perhaps a secretion.

14. **Hydrops of the Gall Bladder.**—From a chemical examination of two cases of occlusion or atresia of the cystic ducts, Sollmann deduces the following conclusions: The contents of the human gall bladder in cases of obstruction of the cystic duct, whether this is congenital or through a gallstone, consists in a dilute solution of true mucin, of the molecular concentrations of the serum, devoid of bile acids or pigments, of ferments and of sugar. Traces of coagulable proteid may be present. No nucleoalbumin was found. The gallstones producing the obstruction consisted essentially of cholesterin.

16. **Physical Training.**—In this fifth section of his series, Lydston gives the details of muscle training, calling attention to the importance of the subjects fixing their attention on special groups of muscles. He also remarks on the vital importance of training the abdominal muscles, which he believes constitute the keynote of the athlete's body. The details of his paper can be best studied from the paper itself.

23 *Transportation and the Ophthalmic Referee. Justin L. Barnes.
24 Treatment of Infantile Convulsions. (To be continued.) Adah McMahon, Edward M. Thompson, H. R. Coston, G. J. Ellis and W. D. Macon.

19. **Complications of Abdominal Surgery.**—Morris first notices the complications due to anesthesia, such as chloroform paralysis of the vasomotors, the effect of ether on the kidneys and stomach and bronchial membranes. He has never in his observation met with a death from the anesthetic, but, in a number of cases, he has been anxious. Ether complications are not certain as regards prognosis, but are usually transitory. In some cases where acute nephritis has existed this seems to have been relieved by the anesthetic. Iodoform poisoning is also noted, as well as hemorrhage. The former is often mistaken for septicemia, but there is a striking difference, in that the septic wound looks ill as well as the patient, while in iodoform poisoning the wound appears to be doing very well, while the patient is not. He has seen one death occurring from iodoform poisoning after removal of all sources of the intoxication. The danger of shock in too long operations is also important, as well as sepsis.

20. **Hereditary Syphilis.**—Griffin reports a number of cases showing the mistakes in diagnosis that have been made in regard to this condition. He remarks that it is a common mistake to suppose that Hutchinson teeth are present as a rule; in fact, they are a rarity. The reason cases are not diagnosed is largely due to the reliance placed on this rare sign, the lack of information as to the manifestations of hereditary syphilis, and neglect to examine the buccal cavity.

21. **Tuberculosis.**—Cobb reviews some general facts and theories as regards tuberculosis, and is inclined to the belief that the danger of bovine tuberculosis is not altogether an imaginary one, though he admits that nearly all human tuberculosis is contracted by inhalation.

23. **Transportation and the Ophthalmic Referee.**—The importance of eye examinations of railroad employes, etc., is insisted on by Barnes, who criticizes the methods often employed, especially by lay examiners. Complete and accurate records should be kept, and the tests be thorough for color sense, vision and hearing. Lay examiners should submit all but the simpler, less complex cases to the medical referee, who should exercise a general supervision over the whole examinations. The rules for examining should not be left to private corporations, but should be regulated by the state.

27 *Report of a Series of Cases of Movable Kidney. H. D. Chadwick.
28 The Composition and Alcoholic Content of Certain Proprietary Foods for the Sick. Charles Harrington.
29 A Case of Habitual Dislocation of the Shoulder Joint. J. Collins Warren.

26. **Uhlenhuth's Test.**—Austin has experimented on the Uhlenhuth test, injecting rabbits and guinea-pigs several times with human blood to produce a serum containing precipitin for the human blood. Following Uhlenhuth's directions exactly he found the test not as fully applicable as it had been represented, and that it can be employed only under very limited conditions. Other fluids of the human body, like effusions and exudates, were of little value, and fluid from placentas could only be used when it was perfectly fresh. Much longer time and more repeated injections were necessary than he had been led to suppose. His experiments are given in detail.

27. **Movable Kidney.**—Chadwick has treated, during the last three months, twenty-eight patients suffering from symptoms referable to movable kidney, some of which are described in detail. He thinks the proper treatment of the affection depends more on the severity of the symptoms than on the amount of inability. Movable kidney often causes no troublesome symptoms, but when it affects the patient's health or limits her or his usefulness, there is only one treatment—that is, fixation—that will cure this condition. Palliative treatment has been of no value in his hands.

34 *The Elective System in Medical Schools. Daniel N. Eisendrath.
35 *The Symptomatology of Tabes; an Analysis of 140 Cases of Locomotor Ataxia. Joseph Collins.

36 *Primary Tuberculosis of the Ear Followed by Mastoiditis: Report of Four Cases. M. A. Goldstein.

30. **The Etiology of Colds.**—The indefinite and little understood term, "cold," is remarked on by Walsh, who points out that cold can be only a predisposing cause, while, in most cases, it is a direct bacterial infection that occurs. Occasionally the breathing in of irritating substances may give rise to a catarrhal condition, resembling a cold. He considers that the method of steam and hot water heating in our houses, making no provision for the moisture necessary to keep the air in a properly humid condition, is especially favorable to the production of colds, particularly when it is suddenly changed to the cold air outside. He also notes that such effects are apt to occur when an individual comes out of a warm room, where a large number of persons is assembled or in which there has been considerable dust present, because of the movement of the crowd, dancing or gymnastics. Such places, moreover, are often absolutely shut off from sunlight, theaters particularly, and lose the benefit of this great bactericide. Delicate individuals should be warned of the necessity for avoiding such places, and stronger persons should not go immediately to the outer air without a preliminary delay in the corridors or foyer. Colds in the muscles are also mentioned, which are more often spoken of as neuralgia or rheumatism. The mechanism seems to be paralysis of the vasomotor apparatus in the parts from chill. A striking indication that a cold is due to microbic invasion is the fact that the process is nearly always accompanied by the occurrence of fever. Chilliness gives an indication for the first step in treatment, the elimination of toxic matters from the blood. The use of remedies that tend to lock up the secretions at the beginning of a cold is almost sure to be harmful.

31. **Gastric Surgery.**—The importance of early diagnosis as affecting the mortality of operation is first noted by Hartmann, who has examined twenty-nine patients operated on, noting the results of operation, and finds in non-malignant disease real and permanent benefit is the rule. Some special indications should be followed. A correct diagnosis is important. Atonic dilatation is rarely an indication for surgical interference; medical treatment will suffice. In pyloric stenosis operation is indicated as soon as the diagnosis is made, especially in all fibrous pyloric strictures. We can not be so positive in cases of ulcer of the stomach, as ulceration without complications is generally cured by medical treatment. In chronic ulcer he thinks that surgical treatment is indicated only when mechanical troubles exist and give the pyloric syndrome. Even if this be cured, the diseased cicatrix will produce a fibrous stricture more serious than the previous condition. He does not consider excessive hematemesis an indication for operation, but small and repeated hematemesis requires it. As to operation, he would only perform gastrectomy where an epithelial grafting is feared. Pyloroplasty of the German surgeons is not possible in cases of ulcer or of fibrous strictures of the pylorus in consequence of the rigid state of the tissue. Its rôle is a very limited one; he does not perform the operation. Gastroenterostomy seems, in the non-malignant diseases of the stomach, the best operation. With his technic, which he has described in his *Chirurgie Gastro-intestinale*, he has not observed one case of circulus viciosus in his 53 operations.

32. **Ectopic Gestation.**—Bandler reviews the causes of ectopic gestation and concludes that injury to the cilia is the chief, if not the sole, etiologic factor.

34. **The Elective System in Medical Schools.**—Eisendrath points out the benefits of the elective system in the last two years of the medical course, especially in our large institutions of the present time where otherwise direct contact with the teacher is not so practicable.

35. **Tabes.**—Collins finishes his article on tabes and gives the following percentage of the frequency of the most conspicuous subjective and objective symptoms: Lancinating pain, 90; Romberg sign, 85; loss of Achilles-jerk, 88; loss of knee-jerk, 84; Argyll-Robertson pupil, 77; ataxia of gait, 73; hypotonia, 72; paresthesia, 73; anesthesia, 67; analgesia, 58; bladder symptoms, 55; impotency, 50; crises, 20; ocular paralysis, 10; arthropathies, 5; trophic symptoms, 8; optic atrophy, 14; girdle sensation, 50; deep sensibility, 63; diplopia, 22.

36. **Primary Tuberculosis of the Ear Followed by Mastoiditis.**—Goldstein reports four cases which he considers were primary tuberculosis infection and feels justified in this diagnosis. All of these cases, he says, were seen more than three years ago; 3 are still living, and careful physical examination fails to show any present tubercular affection. There are no evidences in the histories of these cases or in their clinical development, either of acquired or hereditary tuberculosis in the families of these patients. Of the 4 cases, 3 involved the mastoid cells extensively, and showed an unusually active and rapid invasion. All of the cases developed from a pre-existing otitis media suppurativa chronica, and appeared to him as direct infection by the bacillus tuberculosis. In the 3 cases where the mastoid operation was performed, the wounds healed by firm granulations, and all evidences of tuberculous trouble ceased with the removal of the local process. This is in direct contrast to the healing of wounds in patients where the systemic tubercular invasion is present. The data which have been furnished in the cases herein reported all point to definitely localized specific infection of the cavum tympanum and mastoid cells, with the characteristic development of a tuberculous process as it occurs in bone tissue, and with the definite demonstration of the bacillus tuberculosis in 1 case.

44 *An Examination into the Value of Certain Antiseptics Used for the Preservation of Antitoxic and Other Immune Serums. Joseph McFarland.
45 Problems in the Laboratory Study of Diphtheria. F. F. Westbrook.

41. **Spinal Curvature.**—The causes, mechanism and treatment of lateral curvature of the spine are described at length by Young, who treats it by developing the weak muscles by collective or individual exercise, slightly over-developing them; later uniform development of all the muscles, and the use of special movements to prevent relapse. He divides the condition into three degrees: If the curvature entirely disappears on self-suspension it is of the first degree; if it is somewhat affected, but not entirely corrected, it is of the second; and if not affected whatever it is of the third degree. In the latter cases, the prognosis, of course, is very much more unfavorable. The first degree may be cured, the second influenced by treatment, but the last is incurable.

42. **Pneumonia.**—The increase of pneumonia in recent years is noted by Anders, who gives statistics to show that it is a fact. He thinks it may be due to a great extent to certain degenerative tendencies of modern life, and mentions especially the enormous consumption of malt liquors, which has a bad effect in this particular way. As to its contagion he holds there is good reason to regard it as a fact, notwithstanding the denial by Aufrecht. Pneumonia due to the streptococcus has been common of late years, and he calls attention to the differences between that and the ordinary pneumococcic form. It may assume the type of so-called serous pneumonia, which is really a streptococcic process. There are cases of pneumonia that seem to answer clinically to the variety known as typhoid pneumonia, but he finds that many of these are of pneumococcic origin. The typhoid pneumonia and the asthenic type have become much more common of late years, and he attributes them to the causes first mentioned. Leucocytosis

has been attracting attention. He finds a mild form occurs in light cases, but not so commonly as in malignant types. The highest count usually occurs immediately before the crisis and falls remarkably afterward. Jaundice, when it occurs, he thinks, may be in exceptional instances due to an intense toxemia, but it is in nearly all cases an obstructive jaundice. The diagnosis of aberrant cases may be difficult. The treatment is unsatisfactory. We should use prophylactic measures, disinfection of sputum. We have nothing that will destroy the infecting organism, but we should promptly interfere when cardiac weakness or systemic exhaustion threatens. He has much confidence in oxygen by inhalation and also in normal saline solution; hydrotherapy in many cases meets the indications better than drugs.

43. **Tuberculosis.**—Curtin discusses the contagiousness of tuberculosis, which he thinks has been over-estimated; also the futility of legislation against it. He puts considerable stress on the heredity of the condition favoring an outbreak of the disease, and gives cases to show that pulmonary defects in parents before the birth of a child may leave their impression on the pulmonary tissues of the offspring.

44. **Antitoxin Preservatives.**—McFarland finds that formaldehyd is the only really effective antiseptic in antitoxin cultivation. Unless the pain it causes or the poisonous influence of phenol should be held to outweigh the advantages of trikresol, he would recommend that the use of the latter be abandoned.

52 The Influence of Catarrhal Diseases of the Nose and Throat in Producing Speech Defects in Children. G. Hudson Makuen.
53 Atrophic Rhinitis. J. A. Stucky.

46. **Nasopharyngeal Catarrh.**—Atmospheric changes as a cause of catarrh of the respiratory tract are first noted by Richardson, who says the occurrence of acute colds in rapid succession sets up a true catarrhal condition, while the modern methods of house-heating, imperfect ventilation, the excessive use of tobacco, alcohol and so on, all have their influence on the production of the disease. Improper clothing is also another important cause. He notices the digestive disorders which may follow it. The constitutional disorders which may predispose, such as lithemia, rheumatism, neurasthenia, tuberculosis, and so on, the local changes in the nasal chambers such as septal deformities, also causing alterations of the mucosa, which are followed by similar changes in the pharynx, are noted.

47. **Nasal and Pulmonary Disease.**—Shurly concludes from a study of chronic nasal affections that it is not feasible to regard chronic nasal or nasopharyngeal disease as especially concerned in producing chronic pulmonary disease. As regards acute pulmonary disease, there are certainly conditions which invite attacks by continuity, producing bronchitis, pneumonia and so on, and making the subjects more liable to other diseases.

48. **Hypertrophic Rhinitis.**—In answer to the question in the title of his article, Schadle gives a definite "No." He discusses the causes of hypertrophic rhinitis, the methods of treatment, the acid caustic method, the use of the electrocautery, of which he is an advocate and the use of the snare for papillary hypertrophy.

49. **Nasal Catarrh and Asthma.**—Eighty per cent. of Farrell's asthmatics were cured by removal of the abnormal condition of the nasopharynx, classed under the general head of chronic nasal catarrh. Of the remaining 20 per cent. one-half were benefited. He has never failed to cut short an acute attack, no matter how severe, with a hypodermic injection of codein or morphin. Atropin 1/100 hypodermically or 2 per cent. cocain solution applied to the nasal chambers he has found will give equally prompt relief. He says in the search for the underlying cause of the bronchial spasm, eliminate cardiac trouble, renal disease, gastric and intestinal disturbances, chronic bronchitis, rheumatism, gout and all dyscrasias of the blood, and then examine the nose and throat. Whatever may be the pathology of asthma, the exciting cause is frequently found in the nasal chambers and the greatest number of cures results from removal of such causes.

50. **Hypertrophic Rhinitis.**—The galvanocautery in this condition has been advocated by Seiler, who describes the technic. He has also found it exceedingly valuable in hay fever if the following simple precautions are observed: Not to attempt any cauterization until the paroxysm is completely passed and all inflammation has subsided, as in the winter months; to cauterize only the small areas of irritability which can be brought into view by the touch of the tip end of a probe, but without cocain, as this drug prevents the erection of the turbinate tissue and interferes with the sensitive spots becoming visible; never use the flat surface of the knife and never cauterize more than three or four of the sensitive spots at one sitting and then in one anterior nasal cavity only. He would not apply it in the posterior pharynx nor during the stage of acute inflammation.

59 *A Contribution to the Differential Diagnosis between Glioma of the Retina and Pseudoglioma. Julius Fejér.
60 On Paralysis of Latero-version. Otto Wernicke.

54. **Primary Epibulbar Sarcoma.**—Verhoeff and Loring report a case of interest as showing the malignancy of this condition, which they discuss at length. Their conclusions are given in substance as follows: Epibulbar sarcoma differs from the usual form in malignancy only so far as it is isolated on the highly resistent cornea and sclera, and comes to operation relatively small. Notwithstanding its malignancy, it rarely penetrates the eye. Recurrences almost invariably, sooner or later appear after abscision and general metastases are not infrequent. Immediate enucleation should be advised in all cases after microscopic diagnosis, but the patient should be consulted as to operation after having been fully informed as to the unfavorable prognosis. They give a brief résumé of the cases reported and an extensive bibliography.

59. **Glioma and Pseudoglioma of the Retina.**—Fejer reports a case and discusses the diagnosis and symptoms of the condition. Errors of diagnosis can not well be avoided.

63 The Ultimate Results of Treatment in Uretero-Vaginal Catarrh of Virgins. John A. Hale.
64 Simple Mania. Cassius D. Mansfield.
65 The Treatment of the Third Stage of Labor. Turner Anderson.

62. **The Stomach and Rectal Tube.**—The surgical uses of these instruments are enumerated by Whitacre, who deals particularly with their therapeutic uses. The stomach tube, for instance, is of special value in intestinal obstruction, in appendicitis and in emptying an overfull stomach. It is of special value, also in cases of cancer of the stomach. It ought also to be employed more where operation has to be performed without preparation on a full stomach, and he thinks the persistent vomiting after anesthesia can often be relieved by washing the stomach out before the patient has left the operating table and while still under the influence of the anesthetic. The uses of the rectal tube are numerous. He mentions espe-

cially the value of high enemata in the treatment of disease where it is not advisable to give nourishment by the mouth, as in appendicitis or other peritoneal affections, also for moving the bowels after abdominal operations. Rectal feeding is also described. We should bear in mind that the rectum does not digest, therefore proper foods should be used and injected at the proper temperature, about 100 F., in the upper part of the rectum. Not more than four to six ounces should be given at one time. The interval between feedings should never be less than four hours, and preferably five or six. The rectum should be washed with sterile salt solution at least one hour before each feeding. The catheter and syringe should be kept in an aseptic condition and the bowels moved daily by a simple soapsuds enema.

February 28.

66 Nephropexy in a Case of Chronic Nephritis. J. Norman Henry.
67 *An Inquiry into the Value of the Irrigation Method as a Means of Aborting and Treating Acute Specific Urethritis. Orville Horwitz.
68 *Trunecek's Serum and Its Value in Disturbed Cerebral Functions Caused by Circulatory Changes, with Reports of Twelve Cases. Alfred Gordon.
69 Report of a Case Illustrating Importance of Operation in Certain Cases of Facial Paralysis. Levi J. Hammond.
70 The Treatment of Carcinoma of the Rectum by Mercuric Cataphoresis. G. Betton Massey.

67. **Gonorrhea.**—The defects of the irrigation method are reviewed at length by Horwitz, who concludes that it will not abort specific urethritis, though it will hasten the terminal stage which is prolonged and difficult to cure. Chronic urethritis and involvement of the deep organs are common sequences. To effect a cure in the later stages of the disease irrigation must be discontinued and other methods employed. It should not be employed in the acute stage of specific urethritis nor should irrigations in the deep urethra by hydrostatic pressure be used in the majority of cases of acute gonorrhea as it is conducive to the development of complications.

68. **Trunecek's Serum.**—This serum, as modified by Léopold-Lévi, has been used by Gordon in a number of cases of arteriosclerosis with considerable benefit in some of them. Its combination in this modification is sodium chlorid, 10 gm.; sodium sulphate, 1 gm.; sodium carbonate, 0.40 gm.; sodium phosphate, 0.30 gm.; calcium phosphate and magnesium phosphate, of each, 0.75 gm. The mixture makes thirteen powders. Each powder corresponds to 15 c.c. of the fluid serum, or 150 c.c. of blood serum. The method employed by Gordon was the internal treatment. He concludes that this combination may be a valuable remedy in some cases of disturbed cerebral function caused by circulatory changes, and this not only by hypodermic and intravenous administration, but also internally. When the iodids, nitrites and other means used in such cases are without avail, Trunecek's serum should be given a trial. Sometimes a combination of both may be necessary. Several days, at least a week, must elapse before the desirable results can be expected. There are cases, however, in which the remedy is absolutely useless.

California State Journal of Medicine, San Francisco.

February.

71 *Symposium on Hydrotherapy—Hydrotherapy. George A. Hare.
72 *Hydrotherapy in Typhoid Fever. Frank L. Adams.
73 *Hydrotherapy in the Treatment of Pneumonia. A. J. Sanderson.
74 *Spinal Anesthesia with Tropa-cocain in Genito-Urinary Surgery. M. Krotoszyner.
75 On Ptomaine Poisoning. E. O. Jellinek.
76 Supplemental Report on Hygiene. H. J. Crompton.

71.—See abstract in THE JOURNAL, xxxviii, p. 1265.

72. **Hydrotherapy in Typhoid.**—Adams' article treats of the advantages of hydrotherapy in typhoid fever, giving statistics showing the decrease of mortality under the improved methods in this disease, from between 40 and 50 per cent. down to almost nothing under skilled care. The technic of the Brand method is described and the objections answered. The beneficial effects of the bath are enumerated at length, also the conditions which contraindicate and do not contraindicate it. Among the former he includes severe hemorrhage, extreme cardiac weakness, peritonitis, great reduction of strength in the third week of the fever, perforation, severe pneumonia or pleurisy and extreme nervousness on the part of the patient in some few cases. For the aged and enfeebled it would also require some modifications. In conclusion, he gives a summary of answers of correspondents in California as to their methods, showing the large percentage in favor of this method of treatment.

73. **Hydrotherapy in Pneumonia.**—Sanderson advises the use of hydrotherapy in pneumonia and describes the method of applying it, the full body pack, leg pack, cold compress, fomentations, cold friction, bowel irrigation, etc.

74. **Tropa-Cocain Anesthesia.**—Krotoszyner has used tropacocain for spinal anesthesia in some 120 cases and highly recommends it. He has never observed the excruciating headache sometimes following cocain injections, and only in a very few cases any disagreeable symptoms whatever. The only danger with this method of anesthesia is in sepsis to the spinal canal and, therefore, he does not use it in private houses. Thus far he has not had a mishap and thinks it no more dangerous than any other form of anesthesia.

Southern Practitioner, Nashville, Tenn.

March.

77 *Treatment of Malaria. D. B. Blake.
78 *Remarks on Surgery of the Prostate Gland. James W. Handley.

77. **Malaria.**—The paper of Blake covers the subject very completely, adopting in full the mosquito theory and insisting on prophylaxis as far as possible by extirpation of the mosquito. He thinks probably the best larvicides are the aniline dyes recommended by Celli, though he has not yet been able to obtain them. Fish in waters are very like dragon flies in the air and are only an adjunct to other methods of destruction of the mosquito. The most important measure of all is protection of houses by wire netting. The location and construction of the dwelling is a matter of some importance. The anopheles do not fly high or far, and it is well to build on elevations, as far as possible from breeding places, and sleep on the second and third floors, having the windows well screened. While quinin is a specific, its use requires some skill and the best time to administer it is at such periods as will ensure the presence of the remedy in the blood in sufficient quantities when it is most flooded by the parasites. The end of the febrile period seems to be the most favorable time. When symptoms are urgent, however, we can not wait for this, and the drug should be given as soon as possible and in such quantities as may ensure its absorption, with other remedies to relieve glandular torpor, and sometimes hypodermics of morphin, if not contraindicated, at the onset of the cold stage may be of use. In some cases with gastric irritability, administration of medicines must be per rectum. Next to the cinchona preparations, arsenic is the most reliable drug. He advocates popular education on the subject of malaria and its prevention as one of the valuable methods of aiding sanitation.

78. **Prostatic Surgery.**—Handley favors Wishard's method of combined perineal section and Bottini cauterization.

81 *Excision of the Epiglottis for Lupus. Talbot R. Chambers.
82 Perichondritis of the Larynx. Marshall R. Ward.
83 Some Critical and Desultory Remarks on Recent Laryngological and Rhinological Literature. Jonathan Wright.

79. **Cleft Palate.**—McKernon describes at length his technic of operation and speaks strongly in favor of tracheotomy as an adjunct. The patient can thus be treated as if the operation were anywhere else in the body, the patient breathing freely through the tracheal tube. The length of time required is reduced fully one-half, and the danger of getting fluid into the trachea, etc., is very much lessened. The operation generally seems successful.

80. **The Falsetto Voice.**—From the study of a case observed which is illustrated by tracings, Natier finds that the falsetto voice is caused by respiratory troubles, which can be corrected

by respiratory gymnastics as the most efficient and rapid method of treatment.

81. **Excision of Epiglottis.**—Chambers reports a case, the second on record at the time of his operation, which was done for a condition which seems to have been lupus, though another diagnosis had also been made.

New Yorker Medicinische Monatschrift.

84 *Die Grenzen zwischen vaginaler und abdominaler Coeliotomie. H. J. Boldt.
85 *Erfahrungen mit perinealer Prostatectomie. F. Kammerer.
86 Xanthoma tuberosum diabeticorum. Edward Pisko.

84. **Vaginal and Abdominal Celiotomy.**—Boldt advises the vaginal operation in a large number of conditions. Suppurative salpingitis, where the pus sacs are low in the pelvis, he would treat by opening through the vagina and drainage, a method which he has employed in some thirty-seven cases, producing nine symptomatic cures, fifteen improvements and only five had to be radically operated on later. He would also use it for ovarian tumors not larger than a man's head, which can be reached through the Douglas cul-de-sac, in degenerative ovaries which produce uncomfortable symptoms, in abscesses of the ovaries and all suppurations which are operable through the vagina. Uterine myomas should only be attacked when they produce uncomfortable symptoms. Submucous myomas amounting to 10 cm. in diameter can be attacked from below by slitting the anterior uterine wall. Small subperitoneal myomas rarely cause trouble. If the whole uterus is to be removed the abdominal method is to be preferred, since, by this method, one can leave intact the adnexa with a part of the endometrium, as recommended by Zweifel. Nervous phenomena and following hysteria are not so likely to occur. He considers, for operations on the uterus for displacements and retroflexions, that the Alexander is the ideal operation. He would close the wound by the Bassini hernia method in case of no suppuration. In mobile retroversions he would not advise opening the abdominal cavity, but the condition is different in fixed retroflexions. Vaginal celiotomy in extrauterine pregnancy is limited to those cases in which the diagnosis is made before rupture and, secondly, to those where hematocele has already formed and expectant treatment is contraindicated. In cancer of the uterus abdominal extirpation has had many supporters. Whether statistics will favor their views time alone will tell. He is at present of the opinion that the vaginal radical operation, with the aid of the galvanocautery, may give as good results as abdominal operations.

85. **Prostatic Hypertrophy.**—Kammerer favors the perineal method in this condition. It radically removes the trouble and prevents relapses. Its mortality is not greater than after the galvanocaustic method.

88 *The Treatment of Acute and Chronic Dysentery. M. Goltman.
89 Kidney Complications in Estivo-autumnal Fever. Ira B. Bartle.
90 A Case of Smallpox, with Sequelæ. W. T. Braun.

88. **Acute and Chronic Dysentery.**—The conclusions warranted by Goltman's experience are given by him as follows:

1. The treatment of dysentery, acute or chronic, by topical application is most rational. 2. Topical applications are useless unless large volumes of fluid are used to distend the bowel. 3. Topical applications, as usually made, are very painful in all cases, particularly in those that are acute. 4. Topical applications, to be thorough and far-reaching, are unbearable to the patient, on account of the extreme pain they cause. 5. Anal divulsion is a prime factor in facilitating the work of flushing the colon. Resistance to the escape of fluid is removed, and it markedly relieves the tenesmus. 6. Anal divulsion, cauterization of ulcers through the proctoscope, passage of a tube high up into the sigmoid through this instrument and thorough distension and flushing of the gut are absolutely impossible without the aid of anesthesia. 7. Anesthesia rather relieved than produced shock in my cases. These patients seemed to take as kindly to chloroform as women in childbirth. 8. In my judgment, one is more likely to overdistend and perforate the gut without anesthesia than with it.

Medical Review of Reviews, New York.

February 25.

91 *Food Preservatives: Their Use and Abuse. Willis G. Tucker.
91½ A Case of Exhibitionism. W. L. Robins.

91. **Food Preservatives.**—Tucker reviews the various methods used for preserving foods, and holds that borax, which has long been used, is not particularly deleterious in the quantities in which it may be ingested in food thus preserved. Still, he thinks it will be advisable to prohibit its use in milk, but not in certain other food products, such as those where small amounts are required, as in butter, cheese and cream, and in dusting of ham or bacon. Salicylic acid has been largely used and, if limited to such things as catsup, which is used in small quantities at a time, it is not likely to do harm, but if used in beer or drinks, of which large quantities may be taken, it is very objectionable. Benzoic acid is considered to be somewhat less objectionable, but its indiscriminate use should not be sanctioned. If, for example, it were added to cider in the maximum quantity recommended, a quart might contain as much as 12 grains, which is certainly too much. The sulphites and bi-sulphites should not be permitted in food. Formaldehyd is principally used in milk, and this ought never to be permitted. It directly interferes with digestion. Betanaphthol is another preservative which should be viewed with disfavor. Saccharin is, perhaps, somewhat better. He is inclined to doubt the wisdom of absolutely prohibiting its employment in the present state of our knowledge. The fluorids are supposed to be comparatively rarely used in this country, but he thinks, perhaps, their use is not so uncommon, and the subject needs further investigation. Pyroligneous acid is used as a substitute for smoking meats and, while we are not perhaps justified in saying that foods thus preserved are injurious, they certainly should not be called "smoked" or sold as such. Abrastol or asaprol, the calcium salt of betanaphthol-sulphonic acid, which possesses marked antiseptic properties, has been more or less used as a preservative, but would seem to belong to a class of compounds which should not be permitted. He thinks, however, that too much extreme legislation should be discouraged. The specific prohibition of certain articles not universally conceded to be harmful is unwise, especially as our present laws specifically forbid the addition to foods of any poisonous substances or any that may render such article of food injurious to the health of the person consuming it, as is now the case in many of the states. He thinks, however, that it would be a good law that would require in the case of every food article, in the preparation of which preservatives other than certain articles, such as sugar, salt, etc., are employed, the fact of such employment and the quantity used, plainly stated on the package. Massachusetts has recently passed a law of this description.

93 Methods and Means for Treating Gonorrheal Urethritis in the Male. James Pedersen.
94 Notes from the Clinics: Epistaxis. Bryan D. Sheedy.

92. **Aseptic Preparations.**—The methods of country surgical practice are mentioned by Morris, who tells how to provide for, impromptu, some of the necessities, such as absorbent cotton, sterilization of vessels and instruments. He advises avoidance of absorbent dressings directly to the wound. As to disinfection of the hands, he considers it can be done fairly well by using a 2000 bichlorid of mercury solution for two minutes and, still better, by scrubbing the hands in a mixture of carbonate of soda, chlorid of lime and water, in which the nascent chlorin gas penetrates the interstices about the nails and hair roots. This gives him the best results in hand sterilization. He is experimenting with a method which, he thinks, will be of value, using a germicidal depilatory for removing the hairs, etc., on the surface about to be operated on. He deprecates the disuse of anesthetics in certain lesser operations, dressing of burns, etc., in country practice and in the smaller towns, and believes that we can not do as good work unless we anesthetize in such cases.

4. Ferran's Phthisiogenic Bacillus and Serum Treatment.—Ferran announced in 1901 that the sputa of tuberculous subjects always contains a bacillus differing from Koch's but able to induce the lesions of tuberculosis in guinea-pigs. He now gives illustrations of the lesions caused by it in his experimental research and argues to prove that the bacillus in question is the Koch bacillus in the state of a saprophyte. Under the influence of the bacteriolysins and agglutinins produced in the organism in which it is living, it undergoes modifications which transform it into the typical Koch bacillus. The tubercles are due to accumulation of leucocytes, dying under the influence of the bacilli, their necrosed bodies forming the mounds known as tubercles. The tubercles may form before the bacilli have become transformed. In the pretubercular stage it is possible to render the organism immune by a serum obtained from animals immunized with the toxins of this saprophyte or phthisiogenic bacillus. After these bacilli have become transformed into actual Koch bacilli, this serum is useless. Tuffier recently succeeded in rendering guinea-pigs tuberculous by inoculating them with pus or tissues absolutely free from Koch bacilli, taken from Dr. Paul Garnault, who, as our readers will remember, inoculated himself with tissues from a cow in an advanced stage of tuberculosis.

10. Modern Therapeutics of Diabetes Mellitus.—Boigey concludes his review of this subject by calling attention to the results obtained by Strebel from local application of arc electric light reflected on the liver region. The skin becomes red and perspires, and after a few days the sugar rapidly disappears from the urine. The number of cases thus treated is not yet conclusive, but encourages further trials. Moubineff uses a current of 25 amperes and 60 volts for the purpose. Boigey regards brewers' yeast as the heroic remedy for diabetes mellitus. The fact that yeast contains a variable proportion of different saccharomyces explains the lack of a constancy in its effects. But they are truly remarkable when a good yeast of a stable composition is used. It insures antisepsis of the intestines and prevents the formation of an excess of sugar. The cells of the saccharomyces have themselves energetic phagocytic properties and may thus destroy a certain number of the intestinal bacteria. In addition, their secreted products are capable of neutralizing the toxins generated by the food, a supplementary indirect mode of intestinal antisepsis. It transforms starchy foods into alcohol. Its ingestion in large amounts in some cases has been known to induce a certain degree of alcoholic intoxication. The invertine or sucrase which it contains transforms cane sugar into glucose, then the zymase or alcoholic diastase intervenes and transforms the glucose into alcohol.

25. Resection of Knee Without Opening the Joint.—The femur is cut with a right-angled point and the tibia with a v-shaped incision to correspond. The upper cul-de-sac of the synovial membrane is dissected in front and detached from the femur behind down to the beginning of the section of the bone. The joint is then detached at the rear, from the front, loosening all its attachments to the other organs in the popliteal space, down to the beginning of the v-shaped section of the tibia, the incision carried outward through the ligamentum patellæ. By this means the joint is removed whole, with no opportunity for the escape of tuberculous infectious matter. Marion gives numerous illustrations of the various steps of the procedure, which he has performed 9 times. In one case the wound was reopened to arrest hemorrhage later, and suppuration followed, requiring amputation of the limb. In a second case the tuberculous lesions in the cul-de-sac were so extensive that it had to be opened. The result was an interminable fistula and death from generalized tuberculosis. This failure is a brilliant commentary on the necessity of refraining from opening a tuberculous focus in resecting the knee. All the other patients recovered in the most satisfactory manner and the operation can be considered to have fully established its usefulness. Consolidation occurred in two to six months. One of the patients insisted on taking off his cast several times a week, and he still has a slight mobility of the parts, but not sufficient to interfere with his work as a farm hand.

33 Continued Discussion of Liqueur and Essence Question.

28. The Alcohol Question.—Duclaux of the Paris Institut Pasteur published in the last *Annales* an account of the researches of Atwater and others on the food value of alcohol, accepting their conclusions and remarking that we must hencefortth treat alcohol with more respect. Laborde and numbers of others denounce Duclaux for thus arraying himself against those who are seeking to educate the public in regard to the dangers of the abuse of alcohol.

30. Local Analgesia with Cocain. Incision of a Panaris.—Reclus has performed more than 7,000 operations under cocain and has never had a death which could possibly be attributed to it. Since he has established the three principal rules for its application he has not witnessed any by-effects from its use. These rules are: 1, never to use a stronger concentration than .5 or 1 per cent.; 2, always have the patient recline during its administration and not get up for half an hour afterward, and 3, always to eat and drink something before arising. It is to the disregard of these principles that dentists owe their misadventures with cocain. Reclus asserts that he has carefully sifted the literature and has been unable to find a single published case of a mishap in which these rules had been followed, or even approximated. In incising a panaris he injects the cocain at the base of the finger in the subcutaneous tissue, inserting the needle at four points and injecting the fluid to form a complete ring around the base, using 6 to 7 cg. in all. The finger is then absolutely insensible and the surgeon can proceed to the most thorough intervention on the panaris. After evacuation and curetting he lays the finger in hot hydrogen dioxid and concludes by dressing with an analgesic salve. The lesion heals completely in a few days. He operates under local analgesia with cocain in more than two-thirds of his current surgery, on hernia, hydrocele, varicocele, in dilation of anus, excision of hemorrhoids, artificial anus, gastrostomy, appendicectomy, ablation of subcutaneous tumors, etc. In the discussion that followed his address, Galippe, Laborde, Lucas-Championnière and Duplay stated that they considered cocain too dangerous for current use and had abandoned it almost completely.

31. New Process of Radiography.—The modification suggested is to render the soft parts visible in the radiogram. This is accomplished by outlining or painting one side of the parts desired with a paint made by mixing with oil, subnitrate of bismuth or red copper in powdered form to the consistency of ordinary paint and applying it with a paint brush.

32. Immunity to Viper Bites.—Boinet had occasion to examine postmortem a man whose occupation had been the ex-

termination of vipers or procuring them alive for Calmette, who paid ten cents apiece for them to use in the production of his antivenom. The man's father had followed the same occupation. Both acquired immunity to viper bites in time, but the son showed no signs of inherited immunity. It increased in the son with the frequency of the bites and diminished as the intervals between them became longer. He found cauterization with a concentrated solution of chlorid of gold and phenic acid extremely effective for local treatment of the bites. His death did not seem to be attributable to the vipers, but was the result of diarrhea from exposure, etc.

34. To Derive Greatest Benefit from Sulphur Baths in Syphilis.—Dresch points out that if sulphur baths are taken after a course of mercurial treatment, the benefits of the latter are annulled to a great extent as the mercury is eliminated by the waters. On the other hand, if mercurial treatment is instituted after instead of before the sulphur baths, the benefits are immeasurably increased as the system is swept and garnished ready for it. In cases of recurring syphilitic manifestations or merely as a preventive measure, the maximum effect is attained by this combination of mercury following a course of hot sulphur waters.

36. Therapeutic Application of Pawlow's Discoveries.—The discovery that the trypsin of the pancreatic juice is impotent unless its action is solicited by the presence of another ferment which is supplied by the duodenum, has suggested that it may be possible to artificially supply this latter ferment. Hallion and Carrion call the extract of the duodenal mucosa of the pig, which they present for the above purpose, "eukinase." They use it with or without combination with pancreatic juice, in gluten capsules, and hail it as the intestinal "eupeptique par excellence," although it is yet too soon for the sanction of clinical experience.

37. Improved Technic of Iodin Treatment of Boils.—Gallois has found that a combination of 4 gm. of metallic iodin in 10 gm. of acetone is much more effective than iodin alone in the abortion of boils and pimples. He applies it on a cotton pledget on a toothpick. If the lesion is in a particularly sensitive region he applies it very lightly, and if the furuncle has been opened it may smart a little. A drop of a solution of cocain may be advisable for timid persons in such cases. According to his experience this treatment will certainly abort a furuncle or pimple if taken in time.

38. Rectal Administration of Chaulmoogra Oil.—Danlos mixes warm 75 c.c. of milk and 12 c.c. of chaulmoogra oil, and injects it per anum in case of gastric intolerance. He has thus given it twelve times in one case of leprosy and the alvine discharges the next day showed no trace of oil, showing that it must have been duly absorbed.

42. Hyposulphite of Sodium in Dental Caries.—Claret extols the prompt relief and deodorizing effect of the application of a saturated solution of hyposulphite of sodium in two cases of dental caries of the fourth degree.

43. Gelatin in Visceral Hemorrhages.—The first case described by Collet was that of a man of 45 vomiting blood. A subcutaneous injection of a 1 per cent. solution of gelatin in artificial serum was followed in fifteen minutes by a slight hematemesis, probably of the blood already in the stomach at the time, after which the hemorrhage was entirely arrested. Recurring hemoptysis in the second case was checked permanently by a single injection of a 2 per cent. solution. In the third case the patient was a man of 27 in advanced tuberculosis, with daily hemorrhages from the lungs. They were not arrested by the injections of gelatin until the strength was increased to 4 per cent. which definitely abolished further trouble from this source. Collet's experience indicates that the increased coagulability of the blood conferred by the gelatin is comparatively transient, and that one need not hesitate to repeat the injections if the hemorrhages recur.

45. Methylene Blue for Tuberculous Ulcerations.—Renon found that tuberculous ulcerations in the mouth rapidly healed over under daily insufflation of methylene blue in powdered form. In three of the five cases the lesions completely healed and in every instance they cleared up promptly, while pain was relieved at once. He is now studying its action on the ulcerative enteritis of tuberculous subjects, and can already announce that the diarrhea diminishes from the first and in some cases is entirely cured.

49. **Idiopathic Congestion of Liver.**—Penkert describes the case of a 2-year-old boy in whom the hepatic veins were obliterated, evidently from some congenital anomaly, and resulting in intense congestion of the liver. He could find only one similar case in the literature.

55. **Generation of Fever Temperature.**—Aronsohn describes researches which apparently establish that the higher temperature in both natural and artificially-produced fever is produced by the muscle tissue. The blood does not seem to be directly involved in it, and it is still undetermined whether the glands are concerned.

64. **Hemorrhages in the Suprarenals.**—Simmonds is prosector at Hamburg and has frequently discovered evidences of minute ecchymoses in the suprarenals in various infectious diseases. He regards them as of toxic origin. He has observed cases in which hemorrhagic infarction of both suprarenals proved fatal with the clinical picture of peritonitis and collapse. Hemorrhage in the suprarenals may be due to a hemorrhagic diathesis, to thrombosis of the veins or bacterial embolism of the capillaries or to trauma. Those noted in the newly-born belong in this last group. The thrombosis occurs generally only in chronically debilitated people, and is not due to an inflammatory process. Bacterial embolism may be discovered in subjects free from either clinical or anatomic signs of a septic infection. He has encountered twelve cases of fatal hemorrhage in these organs. When the hemorrhage is unilateral the prognosis may be favorable but not when both are involved.

71. **Neurofibroma.**—Sorgo relates the particulars of a case observed at von Schrötter's clinic. The neurofibroma originates in the peripheral neurilemma of single nerve fibers. The medullary sheath is first involved and later the axis cylinder. The fibers not involved in the neoplasm are liable to become atrophied from compression, but until this occurs the lesion may develop without causing symptoms. Cross section of the dorsal portion of the cord increases the knee jerks on account of the irritation spreading to the reflex centers in the lumbar cord from the pathologic focus. The cells of Clarke's column are less resistant to morbid processes than the large motor cells of the anterior horns. Neurofibromatosis may be a partial sign of a general disposition to pathologic alterations on the part of the connective tissue over large areas of the body, shown in a tendency to neogrowths, interstitial nephritis, glioma, vascular affections, etc. Even in case of absence of compression of the spine, there may be local edema of the skin and local pain on pressure of the spine, but neither are pathognomonic.

90. **Albumin Fattening.**—The maximum daily amounts ingested in the two cases studied at von Noorden's clinic were 1,800 c.c. of milk; 800 c.c. of cream; 225 gm. of roast beef; 150 gm. rolls; 250 gm. butter and 40 gm. plasmon. One woman gained on this diet in twenty-three days 4.8 kgm., that is, about 10.5 lbs. The other gained in eight days nearly 3 lbs. The details of the metabolism accessible to clinical tests were carefully noted and are given in tabulated form, especially the retention of the calcium salts.

91. **Transmissibility of Human and Bovine Tuberculosis.**—Cipollina reports that a monkey fed with bovine tubercle bacilli cultures contracted tuberculosis with no primary lesions apparent in the gastrointestinal tract. On the other hand inoculation of a calf with humau bacilli resulted negatively. Although these tests are so limited yet he thinks that they suggest that Koch's assertions in regard to bovine and human tuberculosis have led to researches which have established that the bovine bacillus is more virulent for both man and animals than the human tubercle bacillus.

92. **Adenocarcinoma on the Nose.**—The patient was an elderly woman and was cured by electrolysis with no recurrence to date.

112. **Treatment of Fractures.**—The swelling and jelly-like exudation around a fracture last for twelve to fourteen days before the actual callus begins to form. During this first stage it is possible to prevent the atrophy of the parts by massage, while it does not interfere with the final consolidation, which does not commence until after the twelfth day. Borchard has been very successful in an extensive experience with fractures treated on these principles. He applies, personally, massage of the parts from the very day of the injury, with passive movements of the adjoining joints, of course commencing very mildly. He then applies a cold water bandage and places the limb in a splint. He repeats these procedures every day until the twelfth, when he applies an immobilizing cast until about the twenty-sixth day, after which the massage is renewed and the joints mobilized until complete consolidation. By this technic, atrophy of the muscles and stiffness of the joints are completely avoided as also edema later, while the limb retains its normal shape.

113. **Treatment of Old Fracture of Patella.**—The gap was 6.5 cm. when the knee was extended and 10 cm. when it was flexed in the case reported by Sträter. Even in profound narcosis the gap was 3.5 cm. He detached the quadriceps tendon its entire length and cut it in a Z. This allowed the parts of the patella to be brought within 1 cm., and this gap was finally overcome by chiseling off the tuberosity of the tibia. This brought the fragments together and, besides suturing them directly with a silver wire, a wire was passed entirely around the patella. The tendon was sutured to itself and to the muscles; the capsule sutured and the cutaneous wound closed except for two small strips of gauze. The knee can be flexed to 160 degrees at present, and conditions are approximately normal.

115. **Endless Sounding.**—This is the term applied by von Hacker to the method of dilating strictures of the esophagus by introducing drainage tubes of gradually increasing caliber either by way of the mouth or through the fistula. The tube is drawn through by means of a thread. Some introduce the thread by having the patient swallow a piece of shot to which the thread has been tied. Henle has recently devised the method of tying the thread to one or more small scraps of iron and, after these have been swallowed, he extracts the iron through the fistula by inserting a magnet, to which it clings. Another way, with which von Hacker has been more successful, is to pass a gut string through. His latest improvement, which he deems an actual progress, is to use one-half of a gelatin capsule. A fine silk thread about half a yard long is forced into the cup of the capsule by means of a long strip of whalebone or a fine gut string, the end of the thread left long. The whole is then introduced into the stomach, the pressure from above only pushing the capsule cup farther on the whalebone. After it reaches the stomach and after an interval for the dissolving of the capsule, the patient drinks some water, when the thread is released and floats on the water within reach from the fistula. This procedure is so simple and harmless that it can be repeated every day without trouble and the thread removed in the interim, thus sparing the patient the inconvenience of a thread permanently in the gullet and mouth. It may be necessary to slit the open end of the capsule and bend it, possibly gluing it with a solution of gelatin, to render the process surer. When he changes from one tube to a larger, he stretches the upper end of the first tube and inserts the larger tube in it, thus making the change without discomfort to the patient. The first tube of all is drawn over a small hollow, olive-shaped metal tip, fastened to the end of the thread by a knot inside and with a groove on its farther end, over which the drainage tube is drawn and tied. This enables the transition to be made to the tubes from the thread without danger or inconveniences. Both of these appliances are illustrated.

116. **Prophylaxis in Chloroform Narcosis.**—Feilchenfeld's suggestion that strophanthus be administered to excitable persons for a few days before attempting chloroform narcosis has found wide acceptance. Both Tillmanns and Witzel recommend it as a routine procedure, the latter combining it with digitalis. Feilchenfeld states that the heart must be investigated several times, and if found nervously excitable, this excitability must be reduced before the narcosis. The sounds are dull, sometimes slightly clapping. The apex beat is at the normal spot, but is rather diffuse and indistinct; pulse small and rapid. Such persons should take strophanthus for several days before chloroform narcosis, pure or combined with digitalis, not more than five drops of each three times a day. The pulse becomes slower, the agitation subsides, the appetite improves and the patient sleeps well. The pulse must be brought down to 80 before the narcosis should be attempted. In case of actual muscular weakness of the heart or myocarditis, the arrhythmia must be combatted and the pulse slowed. This will require more energetic measures, digitalis and tepid or carbonated baths with, possibly, injections of strychnin, as recommended by the French for arteriosclerosis. Ether is to be preferred to chloroform in these cases. In case of hypertrophy of the heart muscle, preliminary treatment is indispensable and a morphin injection to supplement the narcosis. Profound narcosis should be avoided. In severe myocarditis one must always be prepared for possible acute danger for the heart from the narcosis.

117. **Compression of the Aorta During Operations.**—Dahlgren found the temporary compression of the abdominal aorta, first suggested and practiced by Lennander, an invaluable aid in preventing hemorrhage in a case of cesarean section, and recommends it for all major operations in the pelvis. The compression can be done with the hand, and has thus been done in the cases to date. But this requires an assistant skilled in anatomy and also compels the enlargement of the abdominal incision. To obviate these inconveniences, he has devised an instrument for the purpose. It consists of a long handle with stirrup-shaped end, at right angles to the shaft, and a stout rubber drainage tube is fastened across the base of the stirrup. A second instrument like a two-tined fork is used to apply pressure at the top of the stirrup when the rubber tube has been placed on the aorta. Very gentle pressure is sufficient to ensure hemostasis. By making the stirrup a little wider it is possible to apply compression to the aorta and also to the hepatic and portal veins at the same time, when operating on the liver.

120. **Treatment of Cavernous Tumors.**—Payr has been advocating for a year the treatment of inoperable cavernous tumors by the introduction of a number of pencils or arrows made of magnesium. The presence of these metallic foreign bodies in the depths of the vascularized tumor leads to processes of coagulation and obliteration, which finally terminate in the complete destruction of the neoplasm and a solid healing. He uses magnesium to ensure absorption of the foreign bodies. In perfecting his technic he has found that it is wise to have a number of the smooth magnesium pencils on hand of assorted sizes to fit all conditions. He introduces them through a small tube with a piston, which enables one after the other to be pushed in without changing the position of the tube. The magnesium pencils must be inserted with some regularity in the tumor tissue to obtain the best results.

122. **Simultaneous Appendicitis and Cholelithiasis.**—In differentiating dubious cases the possibility of a simultaneous affection of both appendix and gall bladder must be borne in mind. It is remarkable that this coincidence has not been more frequently observed. Sonnenburg noticed it only twice in 600 operations for appendicitis, and Kehr ten times in 625 gallstone operations, Czerny four times in 317. Becker has encountered it five times in 125 operations for gallstones and has collected twenty-nine other cases published in the literature, including the above.

123. **Improved Method of Determining Presence of Tubercle Bacilli in Urine.**—Forssell receives 1000 c.c. of urine in a glass tube tapering to a point below where there is a glass screw cock. It is set aside for twenty-four hours. The cock is then turned and the lower part of the contents is drawn out into two strong glass pipettes tapering abruptly to a point. The pipettes are then centrifugalized vigorously for fifteen to twenty minutes. Examination of one or several cover glasses, spread with the contents of this tip of the tube after pouring off the supernatant fluid, will decide the question as to the presence of tubercle bacilli. The tubes are cleaned afterward and filled with a 6 per cent. solution of caustic soda for twenty-four hours, after which they are rinsed again and are ready for use.

125. **Artery Suturing.**—Schmitz gives a historical sketch of this operation, and states that lateral suture of an artery has been done in twenty-one cases and nearly always with signal success. The axillary artery was thus sutured in seven; the femoral in five; the iliac communis, the carotid communis or interna in one each, and the popliteal or brachial in three each. The latter arteries are too small, it has been found, for successful suturing. The conditions for success in suturing an artery are smooth edges to the wound and no gap between them. The vessel must be handled as delicately as possible, hemostasis applied very gently, best with the fingers. After the suture is completed gentle compression with a tampon for one to three minutes favors the formation of the clot. The experiences to date indicate that the entire wall can be included in the suture without fear of thrombosis, endarteritis or narrowing of the lumen. The adventitia can be drawn up afterward over the wound and a few stitches taken in it to strengthen it. The needle and thread must be very fine. Catgut was used in four successful cases, but silk seems preferable. The femoral artery was invaginated and a circular suture applied in three successful cases, in two on account of adhesion to a tumor and once on account of a bullet wound. Experimental researches have also confirmed the advantages of this method of treating extensive destruction of an artery. Even in case the lumen of the artery should become obstructed later, it occurs so gradually that there is time for collateral circulation to become established.

126. **Obstacle to Reduction of Old Dislocation of the Shoulder.**—Dollinger has found that the head is caught and held by the retracted and sclerotic subscapular muscle in old cases. All that is necessary to reduce the dislocation is merely to sever the tendon of this muscle near its insertion. The arm can then be easily abducted and the dislocation reduced by Kocher's rotating and raising method as readily as in case of a recent luxation. His experience includes five cases. He illustrates the anatomic relations he found in them, showing the rôle played by the muscle referred to.

137. **Filling for Bone Cavities.**—For three years Moorhof has been plugging bone cavities with a combination of 60 parts iodoform in 40 parts each of spermaceti and oil of sesame. The ingredients are slowly heated together to 212 F. and kept at this point for fifteen minutes, then allowed to cool, while the vessel is constantly shaken to ensure the complete emulsifying of the iodoform. He has now an experience of more than 100 cases thus treated. The filling was always well tolerated. The cavity must be scraped far into sound tissue, as aseptic conditions are indispensable. It is then rinsed with a 1 per cent. solution of formalin and thoroughly dried with a jet of hot air. The filling is warmed in a thermophore to about 122 F., and the cavity is filled with it to the brim. As it penetrates into every crevice there is no danger of hemorrhage, but any exposed vessels in the soft parts are first tied off. The filling hardens in a few minutes; the periosteum and other soft parts are then drawn back over it and sutured without drainage unless there has previously been a fistula, in which case drainage is advisable, as also in intervention on the joints. After all sutures and dressings have been applied, the constricting bandage above is then removed and the limb raised. The dressings are not changed until the second or third week. The after-course is almost invariably afebrile. There may be a slight evening rise the second day. No symptoms of iodoform intoxication were observed in any instance. The filling is gradually absorbed and a bone growth takes its place, but the patient can use his limb freely as soon as the soft parts have healed. In one instance he thus substituted the astragalus and calcaneum in a boy of 12, with caries aperta. Nothing was left of the calcaneum but the periosteum; 200 gm. of filling were required for the cavity. The other foot was operated on a month later, the navicular, cuboid, three cuneiform bones and the bases of the metatarsal bones removed. Both wounds healed rapidly.

140. **Gelatin as a Hemostatic for Children.**—Zuppinger witnessed the death of a girl of 8 with hemorrhagic purpura whose nose had been tamponed to arrest uncontrollable bleeding. The hemorrhage was apparently arrested, but the child died suddenly soon afterward, and the air passages were found full of accumulated blood. Since that time he has made a practice of subcutaneous injection of a 2 to 5 per cent. solution of gelatin in all hemorrhagic affections in children, and has found it invariably successful in controlling the bleeding. He has sometimes used a 10 per cent. solution. Holtschmied has reported that he saved the lives of five infants with melena neonatorum by injection of 15 c.c. of a 2 per cent. solution. In three the effect was immediate; the others required one or two more injections. Others have published similarly favorable results in this formerly hopeless affection. A few drops of a concentrated solution applied to the bleeding point in cases of hemorrhage in the throat, etc., have instantaneously arrested it in many cases.

142. **Rupture of Stomach Mucosa.**—The rupture occurred in a football game; the young man running at full speed was hit in the pit of the stomach by the elbow of one of his opponents. He was able, after a time, to continue playing. Two or three days later he noticed a sharp intermittent pain at the right costal arch, which was aggravated by eating and drinking. The eleventh day, after drinking a large quantity of beer, there was vomiting and sharper pain, and a few days later, after a copious meal, sudden oppression, vertigo, cold perspiration, vomiting of blood and melenic stools. The laparotomy disclosed that the serosa was intact, but a laceration 8 cm. in length was found in the mucosa. The patient made a good recovery after the rupture had been sutured. It is probable that such lacerations from contusion of the stomach region are common, but usually heal spontaneously or present the clinical picture of an ulcer later. This case would probably have run this course if it had not been for the immoderate beer and wine drinking. It suggests the necessity for complete abstinence in cases of gastric disturbances after contusion of the stomach region. The sharp, persistent pain at the costal arch may serve to differentiate the injury.

143. **Strictures of Esophagus.**—Moorhof has been able to close the stomach fistula without a laparotomy in cases of stricture from action of caustics. He incises around the fistula and down to within .5 cm. of its orifice in the mucosa. When the fistula canal thus stands up alone and detached—injury being prevented by a sound inserted in it—he then pushes the entire canal in, turning it wrong side out and suturing the outer orifice and then the abdominal walls above it. By this means the opening of the fistula can heal without interference from the gastric juice. He has treated fistulas into the bladder in the same way with complete success. In one case he describes, all the urine was voided through the large fistula, but after treatment in this way not a drop of urine oozed through. It is necessary to carry the incision a little above and below the circular one. In his experience the Billroth conical bougie has frequently passed a stricture in the esophagus, impervious to all other instruments. These bougies are filled with quicksilver and act by the constant pressure of their weight. He gives the particulars of five cases of nearly impermeable stricture, which he cured by these measures.

147. **Paraffin Prothesis.**—This communication from Gersuny's service describes the experience of the inventor of this procedure. He states that the prothesis has not altered in size in cases treated three years ago.

149. **Phleboliths in Genital Organs.**—In the case described a iiipara of 40 applied for relief from uterine hemorrhage. In the veins around the cervix and along the upper portion of the vagina were found a number of concretions, small balls of calcium phosphate and carbonate. The ovarian and other veins were apparently intact. The uterus was the seat of a hemorrhagic endometritis, but, as it was impossible to remove all the phleboliths that could be palpated, the prognosis is not favorable.

150. **Leucocyte Count in Gynecologic Affections.**—Weiss proclaims from Chrobak's clinic that a negative leucocyte count in the early phases of a gynecologic affection entirely excludes the assumption of a suppurative process. Constant leucocytosis of 16,000 and over points to such a process, but this leucocytosis gradually declines as the affection progresses. It is still high enough, however, by the time the patient seeks a physician to indicate its character.

153. **Pathology and Therapy of Asthma.**—Sihle contributes a long article, in which he seeks to establish that asthma is a neurosis in the respiratory and circulatory domains. There are four elements, hypertonicity of the unstriated muscles of the air passages, hypotonicity in the vascular system, including the heart, a bronchial secretion of nervous origin, and a congestion of the entire mucous lining of the air passages. These four elements can be brought into play by the action of the peripheral nervous system, by irritants circulating in the blood, or by the action of the cortex, that is, the asthma may be peripherigenic, hematogenic or psychogenic. He cites some interesting examples of the benefit that may be derived from treatment along these lines, with therapeutic suggestion as the leading motif, and each element in the symptom-complex receiving its due consideration.

156. **Acute Atrophy of the Bones.**—Kienböck is an *x*-ray expert and has been making a special study of the changes in the bones revealed by the *x*-ray from four to eight weeks after some injury or inflammation of the extremities, especially those developing with much pain or requiring immobilization, fractures, osteomyelitis, joint tuberculosis, contusions or phlegmons of the soft parts. The bone casts a lighter shadow than normal, especially the spongiosa nearest the focus, or the lighter portions may occur in patches. The calcium salts are absorbed and the bone becomes pathologically altered in time. The condition may, likewise, be induced by injuries or affections of the central or spinal nervous systems. Before the discovery of the x-rays it was impossible to diagnose it until in an irreparable state, as the early stages cause little if any symptoms. Treatment must be mainly prophylactic. When this tendency to pathologic softening of the adjacent spongiosa is recognized and its dangers realized, the physician will aim to cure the underlying affection as rapidly as possible. If the *x*-rays show that the softening of the bone has already commenced, especially if in a joint, it must be exercised and massage applied, regardless of the pain it may induce, with Faradization, baths and, possibly, therapeutic passive congestion. In orthopedic treatment of the later ankylosis, luxations, etc., the fragility of the atrophied bone must be borne in mind.

163. **Diseases of the Liver.**—The misconceptions alluded to by White are, first, the common belief that alcoholic excesses are solely the cause of hepatic cirrhosis, while, in reality, some other cause must also be at work to produce the symptom. Nevertheless, the common type of hobnail liver is almost invariably the result of alcoholic drinking. He points out the characteristics of syphilitic cirrhosis, which, however, is so rare that it will be of little clinical importance. Malaria, which is given as the cause of cirrhosis, is, in his opinion, largely imaginary. We have really no obvious cause, except alcoholic drinks, for the usual type and while it is

experimentally true that obstruction of the bile duct will cause cirrhosis, it is rarely clinically, if not almost unknown, notwithstanding the frequent cases of pressure on the duct by cancers, growths, etc. Another misconception is in the attempt to draw a sharp distinction between atrophic and hypertrophic cirrhosis. In considering these, we must exclude Hanot's cirrhosis, which is a separate disease, occurring almost exclusively in children. White holds that there is really no distinction between atrophic and hypertrophic liver, but that the former is an earlier stage of the latter. The presence of ascites in atrophic liver is only natural, seeing that it occurs in the late stages of the disease. He notices the symptoms; ascites, a very serious one; jaundice, which may occur early; swelling of the feet; anemia; hemorrhages, etc. The disease we call alcoholic cirrhosis, which is so frequently associated with the consumption of alcohol, though some other factor is also present, is not a local disease, any more than granular disease of the kidney is a local condition of that organ. He insists on the importance of ascites in the prognosis. If a patient in an uncomplicated case has ascites, he is very near the end. He also notes the occurrence of perihepatitis, the zuckerguss liver of the Germans and remarks on certain symptoms of primary malignant disease, which he thinks occurs in a certain proportion of cases. He takes a midway position between those who hold that malignant disease is very rare and those who, like Friedreichs, claim that it occurs in one-third of all cases. He had in his necropsies about one case of primary malignant disease of the liver to every twenty-four, where it was secondary.

174 A Case of Acute Tetanus with Certain Points of Interest. L. Dimock Saunders.

171. **Skin Inflammations.**—Crocker's second lecture treats first of microbic infection and the conditions which favor it. He also notices the importance of the absorption of intestinal toxins in the production of skin diseases and the part played by the nervous system, especially in special vasomotor areas. Pregnancy is responsible for a few eruptions, the most notable one being herpes gestationis. The influence of season is also mentioned, as in summer and winter prurigo, also the effects of ingesta and drugs. He remarks, in conclusion, in regard to gout as having a primary position as an etiologic modifying factor of dermatitis. While he does not doubt that gouty patients are predisposed to eczema and some other forms, there is no doubt that its influence has been much overrated by the profession.

175. **Fractures of the Lower Extremity.**—Lane criticises the anatomic works, with their various descriptions of the mechanism of the joints of the lower extremity, remarking that the lateral movement of the ankle joint is not extensive. It is a fairly perfect hinge joint. The surgical anatomy, he thinks, is even worse in the text-books. The only method of treating, for instance, in Pott's fracture with displacement, owing to the mechanism of the injury, is by pinning together of the broken parts. Fracture of the tibia and fibula produced by indirect violence is almost always spiral and requires similar treatment, holding the parts in position by wires or screws. The spiral fracture of the femur is brought about in a similar way.. He says it is a pity that anatomists, when writing text-books for students, do not confine themselves to improving on the existing, generally inaccurate, descriptions of the mechanics and functions of the skeleton, instead of attempting, under the title of surgical anatomy, to confuse the student by statements and illustrations which are usually extraordinarily incorrect.

176. **Blood Examination.**—The importance of blood examination is emphasized by French and the methods described, with illustrative cases of the value of the leucocyte count, hemoglobin estimates, red corpuscle counts, etc. Specific gravity is also of some importance, and he describes the method of testing it by a mixture of chloroform and benzene of the specific gravity of the normal blood. A drop of blood put into this will float or sink as its specific gravity varies from the normal and by putting more chloroform or benzene into the test tube, to bring it to exact equilibrium, the figures as read off on the urinometer will determine its specific gravity. He details the blood examination as follows:

> The ear is pricked. 1. Blood films are made and dropped into absolute alcohol and ether. 2. Blood is drawn up into the red-corpuscle pipette to the mark of 0.5, diluted to the mark 101 with Hayem's fluid, quickly mixed, and put aside to count presently. 3. The same is done with blood in the white corpuscle pipette. 4. Blood is drawn up to the mark on the hemoglobinometer pipette, expelled into a little distilled water in the graduated tube, and thus laked. 5. Then another drop is taken in the same pipette and put into the mixture of benzine and chloroform. The pipette should then be cleaned. This is quickly done by drawing distilled water up into it two or three times, blowing it out again each time; then in the same way, drawing up absolute alcohol twice successively, to dehydrate the tube, and, finally, ether in the same way, to remove the alcohol and to leave the tube dry and clean when the ether evaporates, as it does in a few minutes. The determination of the specific gravity may then be completed, and the chloroform and benzine returned to a stoppered bottle for future use; the blood drops are readily filtered out by pouring it through muslin. The hemoglobin estimation may then be continued and completed. Finally, after further complete mixing in the pipettes before samples are taken, the red and white corpuscles are successively enumerated under the microscope. The films wait until next day, and then require but ten minutes for their staining and mounting.

The complete blood examination, without a differential leucocyte count, need not occupy more than three-quarters of an hour; a differential count will take a little longer.

177. **The Lorenz Method in Congenital Hip Dislocation.**—Clarke reviews Lorenz's manipulations, and sums up as follows:

> Lorenz's method of treating congenital dislocation of the hip is based on correct anatomic and physiologic grounds; it is the outcome of an exceptional experience, both of open and subcutaneous operating; in a considerable proportion of cases it gives a perfect anatomic and physiologic result (i. e., it cures a condition hitherto deemed incurable); in a still greater number of cases it affords a permanent functional improvement that relieves the patient of the grievous disabilities which the deformity usually entails if left untreated. In the remaining cases, in which the method fails to give a firm articulation placed anteriorly, the manipulative operation of Lorenz is a necessary preliminary to any subsequent treatment by open operation that may be undertaken. The manipulative operation is free from danger, save when treatment has been too long delayed.

179. **Gastric Tetany.**—Moynihan reports a case with recovery, though the patient afterwards died of pneumonia. The point which he emphasizes is that gastric tetany is not the rare or serious disease which has been described by Frankl Hochwart and others. Of the five cases which he has observed, all were due to simple diseases; gastroenterostomy was performed in all, and all recovered.

THE DISEASES OF WARM COUNTRIES. A Handbook for Medical Men. By Dr. B. Scheube, State Physician and Sanitary Adviser, Greiz. Translated from the German by Pauline Falcke, with Addenda on Yellow Fever, by James Cantlie, M.B., F.R.C.S.; and on Malaria, by C. W. Daniels, M.B., M.R.C.S. Edited by James Cantlie, M.A., M.B., F.R.C.S., D.P.H., Lecturer at the London School of Tropical Medicine. With All the Original Colored Maps, Charts, Illustrations, Etc., Together with Many Additional Plates, from the *Journal of Tropical Medicine*. Second Edition, Revised. Cloth. Pp. 594. Price, $8.00 net. Philadelphia: P. Blakiston's Son & Co. 1903.

CLINICAL TREATISES ON THE PATHOLOGY AND THERAPY OF DISORDERS OF METABOLISM AND NUTRITION. By Prof. Dr. Carl von Noorden, Physician-in-Chief to the City Hospital, Frankfurt a. M. Authorized American Edition, Translated Under the Direction of Boardman Reed, M.D., Professor of Diseases of the Gastro-intestinal Tract, Hygiene, and Climatology, Department of Medicine, Temple College. Part III. Membraneous Catarrh of the Intestines (Colica Mucosa). By Prof. Dr. Carl von Noorden, with the Collaboration of Dr. Carl Dapper. Cloth. Pp. 64. Price, $0.50. New York: E. B. Treat & Co. 1903.

THE MYCOLOGY OF THE MOUTH. A Text-Book of Oral Bacteria. By Kenneth Weldon Goadby, D.P.H. Camb., L.R.C.P., M.R.C.S., L.D.S. Eng., Bacteriologist and Lecturer on Bacteriology, National Dental Hospital. With Illustrations. Cloth. Pp. 241. Price, $3.00 net. London, New York, Bombay: Longmans, Green & Co. 1903.

PROCEEDINGS OF THE AMERICAN MEDICO-PSYCHOLOGICAL ASSOCIATION. At the Fifty-eighth Annual Meeting, Held in Montreal, Que., June 17-20, 1902. Cloth. Pp. 333. Published by American Medico-Psychological Association. 1902.

BACTERIA IN DAILY LIFE. By Mrs. Percy Frankland, Fellow of the Royal Microscopical Society. Cloth. Pp. 216. Price, $1.75 net. London, New York and Bombay: Longmans, Green & Co. 1903.

MEDICO-CHIRURGICAL TRANSACTIONS. Published by the Royal Medical and Chirurgical Society of London. Volume XXXV. Cloth. Pp. 369. London: Longmans, Green & Co. 1902.

SIXTH ANNUAL REPORT OF THE EPISCOPAL EYE, EAR AND THROAT HOSPITAL, Washington, D. C., 1902. Paper. Pp. 54.

REPORT OF THE TRUSTEES OF THE NEWBERRY LIBRARY, for the Year 1902. Paper. Pp. 28. Chicago. 1903.

The Public Service.

Navy Changes.

Changes in the Medical Corps of the Navy, for the week ending March 14, 1903:

Surgeon G. P. Lumsden, detached from the *Hancock* and ordered home to wait orders.

Medical Director J. R. Waggener, commissioned medical director from Jan. 20, 1903.

P. A. Surgeons H. H. Haas and W. H. Bucher, commissioned passed assistant-surgeons from Jan. 10, 1903.

P. A. Surgeons E. O. Huntington, J. B. Dennis and E. Thompson, commissioned passed assistant-surgeons from Feb. 10, 1903.

Asst.-Surgeon B. H. Dorsey, appointed asst.-surgeon March 2, 1903.

Pharmacist I. N. Hurd, detached from the Navy Yard, Portsmouth, N. H., and ordered to Washington, D. C., for examination for retirement, and thence home to wait orders.

Surgeon E. S. Bogert, Jr., detached from the Naval Recruiting Station, Buffalo, N. Y., and ordered home to wait orders.

A. A. Surgeon P. F. McMurdo, ordered to the *Gloucester*.

P. A. Surgeon W. P. Grove, detached from duty with Marine Detachment, Culebra, P. R., and ordered to Naval Hospital, New York, for treatment.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended March 12, 1903:

P. A. Surgeon A. R. Thomas, granted leave of absence for two months from February 25.

Asst.-Surgeon J. W. Kerr, leave of absence granted by Department letter of Sept. 20, 1902, amended so that said leave shall be for one month and fifteen days.

Asst.-Surgeon A. D. Foster, on the return of medical officer in command, relieved from duty at Wilmington, N. C., and directed to proceed to Charleston, S. C., and assume command of the service, relieving A. A. Surgeon F. F. Sams.

A. A. Surgeon L. C. Bean, granted leave of absence for two days.

A. A. Surgeon B. W. Goldsborough, granted leave of absence for one day.

A. A. Surgeon W. E. Patrie, granted leave of absence for fourteen days from February 27.

A. A. Surgeon J. C. Rodman, granted leave of absence for three days.

Pharmacist J. Achenbach, relieved from duty at Port Townsend Quarantine, Wash., and directed to proceed to Port Townsend, Wash., and report to medical officer in command for duty and assignment to quarters, relieving Pharmacist R. F. Troxler.

Pharmacist E. J. Thurston, to proceed to Gulf Quarantine and report to medical officer in command for duty.

Pharmacist C. H. Woods, granted leave of absence for twenty days from March 21.

Pharmacist H. E. Davis, relieved from duty at Louisville, Ky., and directed to proceed to Memphis, Tenn., and report to medical officer in command for duty and assignment to quarters, relieving Pharmacist E. M. Holt.

Pharmacist R. F. Troxler, on being relieved from duty at Post Townsend, Wash., to proceed to Port Townsend Quarantine and report to medical officer in command for duty.

Pharmacist E. M. Holt, on being relieved from duty at Memphis, Tenn., directed to proceed to Louisville, Ky., and report to medical officer in command for duty and assignment to quarters.

PROMOTION.

Asst.-Surgeon H. B. Parker, commissioned as passed asst.-surgeon, to rank as such from March 3, 1903.

RESIGNATION.

P. A. Surgeon A. R. Thomas, resigned, to take effect April 25, 1903.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended March 14, 1903:

SMALLPOX—UNITED STATES.

Alabama: Mobile, Feb. 28-March 7, 11 cases.

California: Fresno, Feb. 1-28, 23 cases; Los Angeles, Feb. 22-28, 4 cases; Sacramento, Feb. 22-28, 3 cases; San Francisco, Feb. 22-March 1, 8 cases.

Colorado: Denver, Feb. 22-28, 10 cases.

Florida: Jacksonville, Feb. 28-March 7, 3 cases.

Illinois: Feb. 28-March 7, Alton, 1 case; Chicago, 12 cases, 4 deaths.

Indiana: Elwood, March 1-8, 6 cases; Evansville, Feb. 28-March 7, 5 cases; Indianapolis, Feb. 28-March 7, 19 cases, 8 deaths.

Iowa: Davenport, Feb. 28- March 7, 1 case.

Kansas: Wichita, Feb. 28-March 7, 2 cases.

Kentucky: Lexington, Feb. 28-March 7, 1 case; Newport, March 1-8, 1 case.

Louisiana: New Orleans, Feb. 28-March 7, 3 cases.

Massachusetts: Feb. 28-March 7, Fall River, 2 cases; New Bedford, 1 case.

Michigan: Feb. 28-March 7, Ann Arbor, 1 case; Marquette, 1 case; Port Huron, 5 cases.

Missouri: St. Louis, March 1-8, 5 cases.

Nebraska: Omaha, Feb. 28-March 7, 2 cases.

New Jersey: Jersey City, March 1-8, 1 case; Newark, Feb. 28-March 7, 3 cases.

New York: Buffalo, Feb. 28-March 7, 1 case, 1 death.

Ohio: Cincinnati, Feb. 27-March 6, 6 cases, 1 death; Cleveland, Feb. 28-March 7, 2 deaths; Dayton, Feb. 28-March 7, 5 cases; East Liverpool, Feb. 1-28, 2 cases.

Pennsylvania: Feb. 28-March 7, Erie, 3 cases; Johnstown, 1 case, 1 death; McKeesport, 1 case; Philadelphia, 17 cases, 4 deaths; Pittsburg, 27 cases, 1 death.

South Carolina: Charleston, Feb. 28-March 7, 2 cases, 1 death.

Tennessee: Memphis, Feb. 28-March 7, 3 cases.

Utah: Salt Lake City, Feb. 23-March 7, 26 cases.

Wisconsin: Green Bay, March 1-8, 1 case; Milwaukee, Feb. 28-March 7, 6 cases.

SMALLPOX—FOREIGN.

Austria: Prague, Feb. 7-14, 6 cases.

Belgium: Antwerp, Feb. 7-14, 1 case; Liege, Jan. 31-Feb. 7, 1 case, 1 death.

Brazil: Rio de Janeiro, Jan. 17-Feb. 6, 14 deaths.

Canada: Hamilton, Feb. 28-March 7, 1 case; Winnipeg, Feb. 1-28, 2 cases.

Canary Islands: Las Palmas, Feb. 7-14, 32 cases.

Germany: Hamburg, Feb. 14-21, 1 case.

Great Britain: Birmingham, Feb. 14-21, 8 cases, 1 death; Dublin, Feb. 14-21, 2 cases; Leeds, Feb. 14-21, 9 cases, 2 deaths; Liverpool, to Feb. 21, 105 cases, 5 deaths; London, Feb. 14-21, 7 cases; Manchester, Feb. 7-21, 52 cases, 3 deaths; Sheffield, Feb. 7-21, 4 cases.

India: Bombay, Feb. 3-10, 53 deaths.

Mexico: City of Mexico, Feb. 15-22, 2 cases, 1 death.

Russia: Odessa, Feb. 7-11, 3 cases, 1 death; St. Petersburg, Feb. 7-14, 75 cases, 14 deaths; Warsaw, Feb. 19-26, 2 deaths.

Spain: Barcelona, Feb. 1-15, 4 deaths; Malaga, Jan. 1-31, 3 deaths; Valencia, Feb. 1-15, 3 deaths.

Straits Settlements: Singapore, Jan. 10-17, 4 deaths.

Switzerland: Zurich, Feb. 7-14, 1 case.

YELLOW FEVER.

Brazil: Rio de Janeiro, Jan. 16-Feb. 6, 75 deaths.

Mexico: Vera Cruz, Feb. 21-28, 3 cases, 3 deaths.

CHOLERA—FOREIGN.

India: Bombay, Feb. 3-10, 1 death; Calcutta, Jan. 31-Feb. 11, 33 deaths.

PLAGUE—FOREIGN.

Brazil: Rio de Janeiro, Jan. 16-Feb. 6, 4 deaths.

India: Bombay, Feb. 3-10, 649 deaths; Calcutta, Jan. 31-Feb. 7, 142 deaths; Karachi, Feb. 1-8, 38 cases, 39 deaths.

Mexico: Mazatlan, Feb. 7-14, 41 cases, 20 deaths; to March 6, 302 cases, 250 deaths.

PLAGUE—INSULAR.

Hawaii: Hilo, March 9, 1 death.

FRACTURES INTO AND ABOUT THE ELBOW JOINT.*

J. HENRY BARBAT, PH.G., M.D.

Instructor of Surgery, Medical Department University of California.

SAN FRANCISCO.

Fractures involving the elbow joint, if not properly treated, will often result in impairment of function, amounting in some cases to complete ankylosis, and when we consider that even slight limitation of the movements of this joint may incapacitate an individual from following the trade of his choice, it behooves us to not neglect even apparently trivial injuries of this joint. Motion is limited by either a malposition of the fragments, the overproduction of callus or the interposition of bone fragments in the joint cavity.

The overproduction of callus is sometimes difficult to avoid; but unless the bone be comminuted we can maintain the proper relation of fragments by either nails, wire, staples or plates, and any piece of bone which finds its way into the joint cavity should be removed. Opening of the joint is fraught with much less danger, so far as the subsequent motion is concerned, than leaving the fragments in faulty positions or loose pieces of bone in the cavity.

Before discussing the diagnosis of elbow-joint injuries I will briefly recall the anatomy of these parts, because without this knowledge we are absolutely unable to correct intelligently any of the various injuries which might befall this joint.

The elbow is a hinge joint; the bones entering into its formation are the trochlear surface of the humerus, which is received into the greater sigmoid cavity of the ulna, and admits of the movements peculiar to this joint, viz., flexion and extension; while the lesser, or radial head, of the humerus articulates with the cup-shaped depression on the head of the radius; the circumference of the head of the radius articulates with the lesser sigmoid cavity of the ulna, allowing of the movements of pronation and supination. The articular surfaces are covered with a thin layer of cartilage and held together by means of a capsular ligament, which is thicker on the sides than in front or back. The joint is lined with a synovial membrane, which is attached to the inner surface of the capsular ligament and reflected on the articulating surfaces of the bones, lining the olecranon and coronoid fossæ, and being continuous with the synovial membrane lining the superior radio-ulnar articulation.

On each side of the lower end of the humerus is found a prominence, the external and internal condyle, the internal being much larger than the external, and therefore more liable to injury.

The articular surface of the humerus is divided by a ridge into two parts, the internal extending lower than the external and known as the trochlea articulating with the greater sigmoid cavity. The outer part is called the radial head or capitellum and articulates with the upper end of the radius. The fact that the trochlea projects below the capitellum produces what is known as the carrying angle of the elbow, so that when the arm hangs naturally with the palm forward there is an angle of ten degrees at the elbow, enabling one to carry a bucket and at the same time rest the elbow on the trunk. Above the trochlea in front is a depression, the coronoid fossa into which fits the coronoid process of the ulna, the

Fig. 1.—Before operation.

olecranon being received into the olecranon fossa just above the trochlea behind. The upper end of the ulna presents two processes and two cavities, the olecranon process is a thick curved piece of bone which is continuous with the posterior border of the ulna and gives attachment to the triceps muscle and the posterior portion of the capsular ligament of the joint; the coronoid process projects horizontally forward from the upper and front part of the ulna, giving attachment at its base to the brachialis anticus and the anterior portion of the capsular ligament. The greater sigmoid cavity is formed by the olecranon and coronoid processes, the lesser sigmoid cavity is a narrow depression in the outer side of the coronoid process which articulates with the side of the head of the radius. The upper extremity of the

* Read before the Alameda County Medical Association at the October meeting.

radius is called the head and presents a shallow depression on top; the circumference of the head is round and smooth and rotates in the lesser sigmoid cavity, being held in place by the orbicular ligament.

A knowledge of the development of the ends of these bones is of great importance in the treatment of fractures in children, and the text-books give only a general idea

Fig. 2.—Before operation.

of the time and manner of development. I have taken a large number of skiagraphs of elbows of children, the ages varying from 1 to 15 years, and I find that the beginning of ossification in the various centers depends, not only on the age, but on the general development of the child. In some cases a center of ossification would

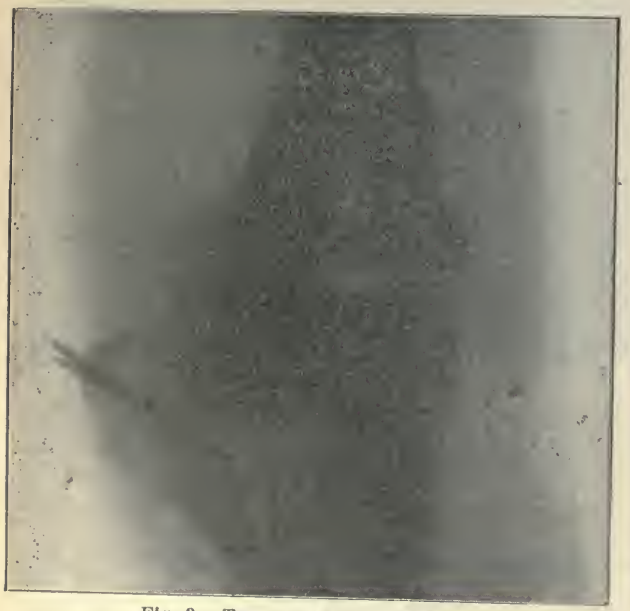

Fig. 3.—Two weeks after operation.

show three years in advance of the text-book time, and in others would be later. It was noticed, however, that, as a rule, the *x*-ray showed the ossific center at least one year sooner than the books would expect.

The diagnosis of fractures of the elbow joint can not be accurately made without the *x*-ray. I do not mean to be understood that the *x*-ray takes the place of palpation or that a correct diagnosis can be made by anyone by simply looking at a skiagraph of an injured joint; but I do say that, without one or more well-made skiagraphs taken in the proper planes, no surgeon can venture to make an accurate diagnosis of fractures involving the elbow joint.

In fractures of the shafts of long bones we often get functionally good results, even when the fragments have not been accurately adjusted, but in fractures involving the joints, and especially the elbow joint, we can not expect any such results, and we must see that all the broken parts are placed in their normal positions and retained there until union has taken place.

The following case is of interest on account of its rarity; I have not been able to find one recorded which was similar in character:

G. M., aged 16, was sent to me for examination three weeks after having received a fall on the elbow. The arm had been treated by means of a right-angled splint, which had been removed every few days and readjusted. At the end of three weeks the joint was found to be immovable, allowing neither extension nor flexion. Pronation and supination were almost

Fig. 4.—Nine weeks after operation.

normal. The carrying angle was very much increased, and the internal epicondyle was much flatter than that of the other arm. Slight crepitus was elicited while making pronation or supination. Two *x*-ray plates were taken at different angles, and showed that the internal epicondyle had been broken off and was lying between the trochlea and the greater sigmoid cavity, with the broken surface in contact with the cavity. The capitellum showed a small piece chipped off, but in proper position.

Operation was advised and accepted. An incision was made directly over the internal condyle down into the joint, and the epicondyle found exactly as shown by the *x*-ray. The flexor and pronator tendons were still attached to it, and their function had not been impaired. The internal lateral ligament had, of course, been torn through and the ulnar nerve was found surrounded by inflammatory tissue, and was dissected loose. The epicondyle was lifted from its position with great difficulty, first on account of the adhesions which had formed and also because it could not be tightly grasped without danger of crushing.

After its liberation it was found that the muscles had contracted to such an extent that it was impossible to bring the fragment to its original position, and it had to remain about one-fifth of an inch lower down than normal. While

in this position I drove two wire nails directly through the epicondyle into the condyle, being careful to avoid entering the olecranon or coronoid fossa. The lateral ligament was brought together with catgut, and the skin with silkworm gut, leaving the heads of the nails protruding.

The arm was put up in a straight splint and left for two weeks, after which one nail was taken out and passive motion begun; the other nail was removed one week later. There was considerable callus surrounding the humero-ulnar articulation, but under massage this is gradually diminishing and the patient is at present, nine weeks after the operation, able to move the joint without much pain, and can extend the forearm almost to a straight line and flex it to beyond a right angle. There is yet some callus to be absorbed, and we may expect that after another month or two the arm will be in almost perfect condition. The carrying angle is still too great, showing that there is some thickening of the synovial surfaces between the ulna and humerus. The small piece which was chipped off from the capitellum is causing very little, if any, disturbance, and appears to be united to the humerus in good position.

To obtain skiagraphs which will show accurately the injury to an elbow we place the arm with the two condyles of the humerus on the same plane as the plate,

Fig. 5.—Nine weeks after operation.

and the forearm extended as far as it will go, this will show any fracture of the lower end of the humerus, or of the condyles, but will not give an accurate idea of the direction of oblique fractures which run in an antero-posterior direction. It will therefore be necessary to take another skiagraph, with the plane of the condyles at right angles to the plate, and the forearm flexed at almost a right angle and the hand pronated. It may be impossible in some varieties of injuries to get the arm in these positions, but we should strive to come as close as possible, because if we habituate ourselves to certain positions and relations we can with greater ease detect any deviation from the normal, and right here let me remark that no one is capable of interpreting a skiagraph of an injured bone or joint who has not made a study of the skiagraph of bones and joints which are known to be normal.

In diagnosing elbow injuries in children under 18 years of age it is absolutely necessary to take pictures of the sound as well as the affected side, on account of the fact that the epiphyses are either entirely cartilaginous or not yet united to the shaft of the bone. It may be difficult to tell whether there has been a dislocation of one of the epiphyses by either palpation or x-ray if there is no deformity, but by comparing the skiagraphs of the two sides the slightest abnormality can be detected, and I find it better in all cases to keep the arm splinted for at least two weeks when the child complains of pain or shows a disinclination to use the arm.

Fractures of the olecranon are best treated by driving a long wire nail through the tip of the process down into the shaft of the bone; this may be done without cutting if the fragment can be properly adjusted and there is no blood between the pieces, otherwise it is better to cut the skin and clean out the blood first. Broken-off condyles are retained in position by means of steel staples, one prong of which is driven into the shaft of the bone and the other prong into the fragment. In using staples or nails which have to enter the compact tissue of the bone it is necessary to drill holes before driving them in, being careful that the holes are just small enough to hold the nail or staple tightly. In cancellous bone nails may be driven in without drilling.

First make your diagnosis, then adjust the fragments, and if a splint will not retain them in proper position, make fixation as I have indicated, being particularly careful as to your asepsis, and your results will be very much superior to those obtained by the expectant plan.

590 Sutter Street.

A CASE OF SUCCESSFUL REMOVAL OF AN ENLARGED SPLEEN,

WITH TWISTED PEDICLE, ADHERENT TO THE RIGHT SIDE OF THE PELVIS, IN A WOMAN PRESENTING MULTIPLE NODULATION AND PIGMENTATION OF THE SKIN.

J. CLARENCE WEBSTER, M.D.
CHICAGO.

WITH REMARKS ON THE MEDICAL ASPECTS OF THE CASE.

THEODORE TIEKEN, M.D.
CHICAGO.

NARRATION OF THE CASE.

Mrs. W., Jewess, housewife, aged 38, was admitted to my service in the Presbyterian Hospital, Chicago, Aug. 25, 1902, with pain in the pelvis and lower abdominal region, generally of a dull, aching character, varying in intensity and radiating occasionally to different portions of the upper abdominal and thoracic regions.

The pain is most marked in the right iliac region, where there is a swelling which varies in size and consistence from time to time. The latter is usually tender when palpated. There is always great aggravation of her suffering during menstruation.

She also complains of frequent and occasionally painful micturition, shortness of breath, intense headaches, swollen feet, leucorrhea, and of occasional bloody stools. She also complains of a swelling in the region of the navel, of discoloration and nodulation of the skin.

Duration and History.—The patient states that she first noticed the swelling in the right iliac region 17 years ago, after the birth of her first child. It was then flat and about as large as her hand. It gradually increased in size, becoming more and more painful and sensitive to pressure. Eight years ago she was seized with intense agonizing pain of a colicky nature, and ever since has suffered from similar attacks every two or three months; they usually last one or two days, and the patient is compelled to inhale chloroform in order to obtain relief.

Frequently after the attacks the urine was noticed to be dark, reddish-brown in color and somewhat foul-smelling.

As it was voided there was usually smarting in the bladder and urethra. The iliac swelling at other times became smaller, less firm in consistence and less tender.

The pigmentation and nodulation of the skin have been present for many years. They began to appear about a year after the development of the swelling in the right side.

Four years ago, an abdominal section was performed in another hospital and the patient states that the operator informed her that the swelling was an inoperable tumor of the right kidney and that nothing could be done. A few months after this operation the abdominal wall cicatrix began to stretch and a ventral hernia gradually developed.

Sexual History.—Menstruation began at 13. The type has always been irregular until the time of operation four years ago; ever since it has been fairly regular, of the 28-day type. The duration is usually 5 days, the flow being profuse. There has always been some pain in connection with the periods, most marked immediately before and after. Since the appearance of the swelling in the right iliac region, the pains have been very severe at menstrual periods. She states that at these times she frequently passes blood in her stools.

Previous History.—In early life she had various diseases of childhood. As a young woman she lived in the south and had malarial attacks several times. At the age of 22 she had pulmonary hemorrhages during a period of eight months, losing considerably in weight at the time; five years ago she was also similarly troubled for several months. She coughs occasionally, and states that she "catches cold in her chest" easily. At the age of 26 she had typhoid. For many years she has been troubled at times with pains in various joints; they have sometimes swelled and become very painful. She states that on two or three occasions she has been jaundiced.

Family History.—Her father was alive when she last heard of him, two years ago. Her mother died at 66 of measles. She has two sisters who are well. Several members of her father's family have had tuberculosis.

State on Admission.—The patient is somewhat poorly nourished and has a haggard expression. The skin of the face is of a light brown hue, the pigmentation varying in different parts. The trunk is also pigmented, there being a generally diffused light brown tint, as well as patches of deep brown, varying in size from one to six or eight centimeters in diameter. Many cutaneous nodules, varying in size from a pin head to a marble, are also visible. Some are entirely below the surface, some bulge the latter slightly, others are sessile or pedunculated.

Abdomen.—In the middle line there is a vertical scar extending downward five inches from a little above the navel. The latter is everted and stretched as is the scar tissue. The recti muscles are 3½ inches apart in the region of the navel as the patient lies on her back. In the erect posture the intestines bulge between the muscles, forming a hernia in almost the whole length of the scar. In the right iliac region a swelling is visible, being very prominent. It is firm in consistence and can not be moved. The patient states that it is tender when it is palpated firmly. Its upper end is about 2 in. above the level of the anterior superior iliac spines. It descends below the pelvic brim, where it is in close relation to the right half of the retroverted uterus.

Bimanual Examination.—The uterus is somewhat enlarged, retroverted and fixed. The appendages are matted and fixed at the sides of the uterus and are somewhat sensitive. The right half of the pelvis is occupied by the lower portion of the iliac swelling. It is close to the uterus with which it appears to be connected.

Examination of Blood.—(Made by Drs. Farnum and Barnhardi.) Erythrocytes per c.mm., 4,016,000; leucocytes per c.mm., 16,800; hemoglobin, 70 per cent.

Urinalysis.—Amount in 24 hours 400 c.c., sp. gr. 1,010, acid. Slight trace of albumin, a few leucocytes and epithelial cells. Some erythrocytes. A few hyaline casts. Urates.

On August 29 the interior of the bladder was examined. The mucosa was normal save behind the trigone, where there was a small, deeply-congested area.

The ureters were catheterized. The left catheter was easily passed. The right one met with an obstruction about 3 inches above the bladder, but, after a little manipulation was passed upward about 10 inches. The catheters were left *in situ* for 1¼ hours. The specimens of urine differed somewhat, as follows:

RIGHT SPECIMEN.	LEFT SPECIMEN.
Very turbid.	Quantity 3½ times that of the right side.
Consid. serum-albumin.	Slight serum-albumin.
Urea 1.3.	Urea 1.7.
A few hyaline casts and one blood cast.	No casts.
Small transitional epithelial cells.	
Many erythrocytes.	Some.
Few leucocytes.	Few.

Temperature and Pulse.—The temperature varied considerably while the patient was in hospital. It was usually normal, but frequently varied from 99 to 102. The pulse varied greatly, from 72 to 120.

X-ray examination of the abdomen and pelvis revealed no calculus.

The patient was kept under observation until September 9, when she was sent home.

Treatment.—She was placed on milk diet, a mixture of sodium iodid, sodium chlorid and sodium phosphate being administered. The daily quantity of urine gradually increased. Slight variations in the size and sensitiveness of the iliac swelling were noted from time to time.

September 17 the patient returned to hospital and was prepared for abdominal section. Previous to operation the hemoglobin was 80 per cent. and the leucocytes 8,800 per c.mm. The 24-hour quantity of urine was 2,000 c.c.; no casts were found in it and only a few erythrocytes and leucocytes.

Operation.—September 25 the abdomen was opened in the middle line. Both kidneys were found to be normal in size and position. The liver was normal. The stomach and transverse colon were lower than normal. Anterior to the iliac swelling were small intestines and omentum. The latter enveloped a considerable portion of the swelling and was widely adherent to it, as well as to the parietes and pelvic viscera.

The swelling proved to be an enlarged spleen. It was adherent to omentum, intestines, iliac fossa, bladder, right appendages and uterus. The vermiform appendix was enlarged and buried in adhesions on the posterior surface of the spleen. Extending from the hilum of the spleen a rope-like band extended upwards and to the left towards the celiac axis. It consisted of the twisted splenic vessels. I estimated that the pedicle of the spleen had in it between two and three twists. The vein was enormously enlarged, especially near the spleen, where its diameter was nearly an inch. The uterus was retroverted and the appendages buried in adhesions. The small intestines and sigmoid flexure were firmly adherent to the uterus and broad ligaments.

After removing a large portion of the omentum, the adhesions around the spleen were separated with some difficulty. The vessels in the pedicle were secured with catgut, and the spleen was removed. As the patient's pulse had become very rapid and irregular, it was deemed advisable not to interfere with the pelvic organs. The abdomen was filled with salt solution and closed, the separated recti being well approximated.

The patient made a good recovery. During the first two days the pulse varied from 90 to 120, but thereafter was satisfactory.

On October 24 she returned home, feeling in good condition. There has been a considerable clearing up of the skin-pigmentation since the operation, but no change has been noticed in the nodules.

Report on the Spleen.—The spleen weighs 28 ounces and measures 7 in. vertically, 4 in. in breadth and 3½ in. in thickness. It is dark colored, the capsule is thickened and covered with adhesions and portions of omentum. Dr. Hamley's report as to the microscopic examination is as follows:

1. Marked congestion, uniform throughout the spleen, only a slight degree being observed within the Malpighian corpuscles.

2. A moderate increase in the connective tissue trabeculæ and walls of blood-vessels.

3. Some thickening of the capsule.

4. Mast-cells are very numerous.

5. In some parts there is increased pigmentation.

A few skin-nodules were removed for examination and Dr. Hamley reports on them as follows:

Each consists of fibro-cellular tissue, varying in compactness and in the character of the cells; the latter are mostly round. In some parts hyaline degeneration is found. Many mast-cells and plasma-cells are seen, the former not being found in the degenerated areas. Mitotic figures are occasionally noticed in the connective tissue cells. The nodules contain a few capillaries. The epithelium of the skin is considerably thinned over some of the nodules.

REMARKS ON THE CASE.

The case presents features of considerable interest. In the first place there was great difficulty in determining the nature of the iliac swelling. The patient's statement that her abdomen had been opened four years previously and that the operator had stated that the mass was an inoperable right renal tumor naturally biased our judgment. In view of the long duration of the swelling and its slow increase in size, malignancy could not come into consideration. If a new growth it seemed more likely to be some form of benign fibrous fibro-cystic or fibro-lipomatous swelling, similar to those described by Wilks, Bristowe, Billroth and others. Wilks in 1869 described such a tumor of the right kidney as large as a child's head, which had caused hematuria and pain for ten years. The pigmentation of the skin suggested an involvement of the suprarenal bodies.

The clinical symptoms, however, suggested strongly hydronephrosis of the intermittent type, associated with a calculus or with stricture or torsion of the ureter. There were severe crises of pain requiring the administration of chloroform, the swelling varied in size and became smaller when urine was passed after the attacks of pain. The urine was frequently dark as if containing blood, and on ureteric examination blood was found in it. The presence of leucocytes in the urine and the irregular elevation of temperature suggested an infective process in the supposed renal swelling. No stone was found on *x*-ray examination. The passage of a catheter for ten inches into the right ureter did not seem consistent with the supposition of ureteric torsion, especially when the kidney appeared to be partly within the pelvic cavity. An obstruction was felt a short distance above the bladder, but the catheter passed it without great trouble. The patient's statement as to the increase and diminution in the size of the tumor was then thought to be exaggerated or to be explained by a rising and falling, merely due to filling and emptying of the bladder. Slight variations in the size and consistence of the swelling were certainly observed by me, but were not at all marked. The possibility that the tumor might be a pedunculated uterine fibroid, a fibroma or dermoid of the ovary or a large right hydrosalpinx was considered, but only by conjecture. Such swellings might be of long duration and might cause pressure on the ureter, especially if associated with marked displacement of the pelvic viscera and cicatrizations following old peritonitic adhesions. It was never supposed that the swelling might be a spleen.

A wandering spleen may undoubtedly sometimes enter the pelvic cavity, and an enlarging spleen, e. g., in splenic anemia or leucocythemia, may descend into the pelvis on the left side and be mistaken for a tumor of pelvic origin. The present case is the only one recorded, so far as the writer has been able to ascertain, in which an enlarged spleen has become fixed in the right side of the pelvis.

The variations in the size of the tumor were probably associated with increase and diminution of the quantity of blood in the spleen, associated with disturbances in the circulation due to torsion of the pedicle. The attacks of pain were similar to those associated with torsion of the pedicle of ovarian and fibroid tumors, local peritonitis having developed leading to adhesions between the spleen and surrounding structures. Bland Sutton has pointed out that retroversion of the uterus may be caused by the descent of a wandering spleen into the pelvis. It is extremely likely that this relationship existed in the present case, the firm adhesions which covered the uterus and appendages having resulted from peritonitis secondary to splenic torsion.

MEDICAL ASPECTS OF THE CASE.

THEO. TIEKEN, M.D.

Blood Examination.—The first examination made was six days after operation, Sept. 30, 1902: Erythrocytes, 4,300,000; leucocytes, 22,000; hemoglobin, 60 per cent (Dare); color index, .69.

(*a*) The fresh specimen shows corpuscles to be of normal size, rather pale, no poikilocytosis. No malarial pigment or living organisms found.

(*b*) Stained specimen (Ehrlich's triacid mixture). Erythrocytes normal size, stained uniformly. No macrocytes; few microcytes; two normoblasts; no megaloblasts; no microblasts; no poikilocytosis; no myelocytes.

(*c*) Differential count of two hundred leucocytes: Small mononuclears, 14 per cent.; large mononuclears, 7 per cent.; transitional forms, 1 per cent.; polymorphonuclear, 77 per cent.; eosinophiles, 2 per cent; no mast cells.

Second examination, nineteen days after operation, Oct. 13, 1902: Erythrocytes, 4,408,000; leucocytes, 13,000; hemoglobin, 72 per cent. (V. Fleischl) 73 per cent. (Dare); color index, .80.

(*a*) Fresh specimen shows normal shape and size of red corpuscles, slightly pale; no malarial organisms or pigment seen.

(*b*) Stained specimen shows similar picture to No. 1; no myelocytes.

(*c*) Differential count of two hundred leucocytes: Small mononuclear, 13 per cent.; large, 17.5 per cent.; transitional forms, 1.5 per cent.; polymorphonuclear, 66.5 per cent.; eosinophiles, 1.5 per cent.; no mast cells.

Third examination, twenty-six days after operation, Oct. 20, 1902: Erythrocytes, 4,420,000; leucocytes, 11,200; hemoglobin, 77 per cent (V. Fleischl); color index, .82.

(*a*) Fresh specimen same as previous examinations; no malarial organisms.

(*b*) Stained specimen: two red corpuscles were found containing a ring of pigment very similar in appearance to the tertian malarial organism. Although unable to find organisms in the fresh specimen, these two were so characteristic as to leave but little doubt. There was no extra-corpuscular pigment in this specimen, which makes it all the more improbable that these were artefacts.

(*c*) Differential count of four hundred leucocytes: Small mononuclear, 12 per cent.; large mononuclear, 17 per cent.; transitional forms, 1.8 per cent.; polymorphonuclears, 65.2 per cent.; eosinophiles, 2 per cent.; no mast cells; no myelocytes.

One large mononuclear cell was seen with faint granules. Five normoblasts were seen while counting four hundred leucocytes.

Comparing the three differential counts we have the following:

	Per cent.	Per cent.	Per cent.
Small mononuclear	14	13	12
Large mononuclear	7	17.5	17
Transitional forms	1	1.5	1.8
Polymorphonuclear	77	66.5	65.2
Eosinophiles	2	1.5	2
Mast cells	0	0	0

Briefly summing up the differential counts made at different periods after operation, we see the following changes: A slight decrease in the small mononuclear elements; an increase in the large mononuclear type from 7 per cent. to 17 per cent.; a very slight increase in the transitional forms; a decrease in the polymorphonuclear type from 77 per cent. to 65.2 per cent.; no change in the eosinophiles.

I am sorry that it is impossible to compare the differential count before operation, as this was not made, because there was nothing to indicate the importance of such a step before discovering that the tumor was an enlarged spleen. The findings as indicated in the above examinations of the blood correspond so closely to those of previously reported cases of splenectomy that we need not dwell further on this part of the subject.

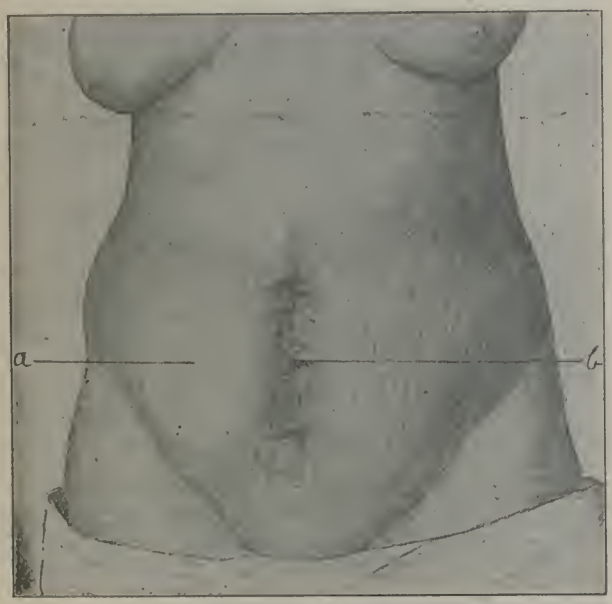

Fig. 1.—Sketch of the anterior surface of the abdomen previous to operation. *a*, Swelling caused by the enlarged spleen; *b*, stretched scar tissue resulting from old operation.

Kurloff's experiments show that the spleen is not indispensable in the guinea-pig and some other animals, as the white corpuscles are formed by the lymphatic glands and bone marrow in sufficient numbers to compensate for the loss incurred by removal of the spleen.

In man, too, it has been found that removal of the spleen is not followed by any serious consequences, numerous cases having been reported in which the operation has been carried out for the relief of certain conditions, e. g., trauma, abscess, tumors, cysts, chronic hypertrophy, cirrhosis, leukemia and splenic anemia. In the latter condition splenectomy has been followed by very satisfactory results and is, undoubtedly, to be regarded as a valuable therapeutic measure.

Da Costa states: "Excision of the spleen in man is followed by a diminution of hemoglobin and erythrocytes, the degree of which is generally believed to be more pronounced than can be accounted for by the simple factor of hemorrhage incident to the operation." As regards the present case, the hemoglobin was reduced to a greater degree than the red cells. No doubt this is to be explained partly by the very slight loss of blood during operation, and partly by the loss of blood prior to operation, from frequent intestinal hemorrhages, hematuria, and possibly profuse menstruation. The leucocytosis was most probably due to the hemorrhage incident to operation, since it rapidly decreased from 22,000 on the sixth day to 11,200 twenty days later. The presence of normoblasts may be attributed to the same factor.

Let us now consider carefully the facts brought out in the history and see if it is possible to arrive at definite conclusions regarding the diagnosis in this case.

Osler has recently reported a series of cases of a disease termed splenic anemia, which he defines as follows: "A specific malady of unknown etiology, char-

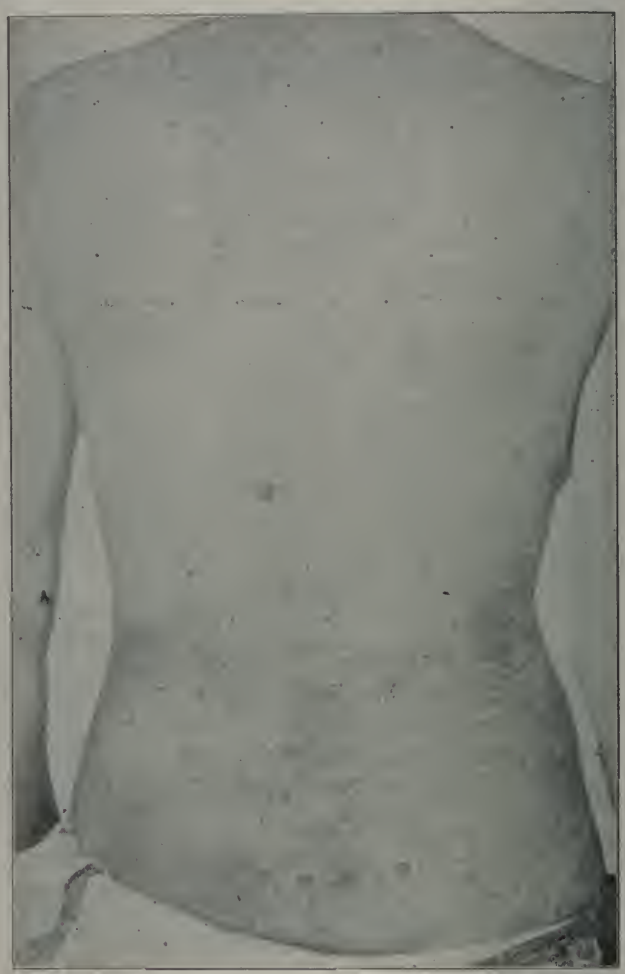

Fig. 2.—Back of patient showing multiple nodulation and pigmentation. The anterior aspect of the trunk presents a somewhat similar appearance.

acterized by a chronic course, enlargement of the spleen, a secondary anemia, a marked tendency to hemorrhage from the stomach, a liability to jaundice, cirrhosis of the liver, ascites and pigmentation of the skin."

In the case under consideration there is no definite etiologic factor explanatory of the various disturbances, although the patient gave a malarial history and had lived in a malarial district. Malaria might account for the splenic tumor, but not for the other signs and symptoms. The history is that of a chronic diseased state, extending over a period of seventeen years or more, associated with enlargement of the spleen. There were the following features: Secondary anemia; a tendency to hemorrhage from the kidney and bowel (the blood passed

in the stools may have come from the stomach); recurring attacks of jaundice; the pigmentation of the skin. Having present so many of the prominent symptoms of a typical case of splenic anemia are we justified in making a diagnosis of splenic anemia? Cases 14 and 18 in Osler's series correspond very closely to ours in every detail, having an enlarged spleen, secondary anemia, pigmentation of the skin, hematuria, jaundice, and in addition, cirrhosis of the liver, which, however, was not demonstrable until late in the disease.

In the case under consideration there was no liver cirrhosis nor any history of ascites. These conditions are, however, usually found only in the advanced stages of splenic anemia. The splenic enlargement is not as large as that reported in most cases of long-standing anemia. Its size might, indeed, be due to chronic congestion and hypertrophy of the tissues secondary to torsion of the pedicle.

In the present case there was a peculiar nodular condition of the skin which came on about one year after the tumor was first discovered. Does this bear any relation to the disease? In reviewing the literature at my command I find no mention of such a condition in splenic anemia. Oertel describes a somewhat similar appearance in a case of leukemia, but there was no such pigmentation associated with it. Kreibich describes another case of leukemic lesions of the skin, associated with some pigmentation, but the patient had been taking arsenic for some time previously, and this might have caused the pigmentation. Pinkus also describes a case of lymphatic leukemic lesions of the skin. Since all of these cases are positively of a leukemic nature, our case is, so far as I can ascertain, the only one of splenic anemia associated with a nodulation of the skin.

Our case was exhibited before the Chicago Dermatological Society, and the opinion was generally expressed that the nodulation was of the nature of a molluscum fibrosum.

A FEW PRACTICAL POINTS IN THE TECHNIC OF NEPHRORRHAPHY AND HERNIOTOMY,

AND A NEW MODIFICATION OF ALEXANDER'S OPERATION.

F. P. CANAC-MARQUIS, M.D.
CHIEF SURGEON OF THE FRENCH HOSPITAL.
SAN FRANCISCO.

In presenting this paper to the medical profession, I wish merely to call attention to a few simple details that I have found of such practical benefit that my results are far superior to what they formerly were.

By referring to my case-books I note that the cases operated on prior to 1890 and in which I followed the technic then in vogue, are not to be compared in practical results, rapidity of healing and permanent benefits, to my subsequent cases, in which I followed the technic here given.

NEPHRORRHAPHY.

An incision 10 cm. long is made 4 cm. from the spine and 2 cm. below the twelfth rib and parallel to it, cutting through the skin, fascia and muscles. The finger is inserted in the incision and the peritoneum is pushed out of harm's way. The fatty capsule of the kidney is caught, opened and resected in the dorsal part of the kidney. The capsule proper is now incised to the extent of 8 cm. on its dorsum, the capsule then freed 3 or 4 cm. in all directions by the finger.

The slight bleeding that follows this denudation is easily arrested by compression. To anchor the kidney, a double silkworm-gut continuous suture is made on each side of the incision, starting at A (Fig. 1), passing through the skin, fat, muscle and capsule proper; taking about 1 cm. of the muscles with the capsule proper and passing out in the inverse order, as shown in Figure 1 at A. The same procedure for the opposite side is shown at B and B′. By pulling these sutures taut, the capsule is drawn to the side and exposes a raw surface of kidney parenchyma about 3 cm. wide and 6 cm. long. A lead nickel-plated shield is threaded and shotted and the shot crushed on these sutures, when moderate tension has been accomplished.

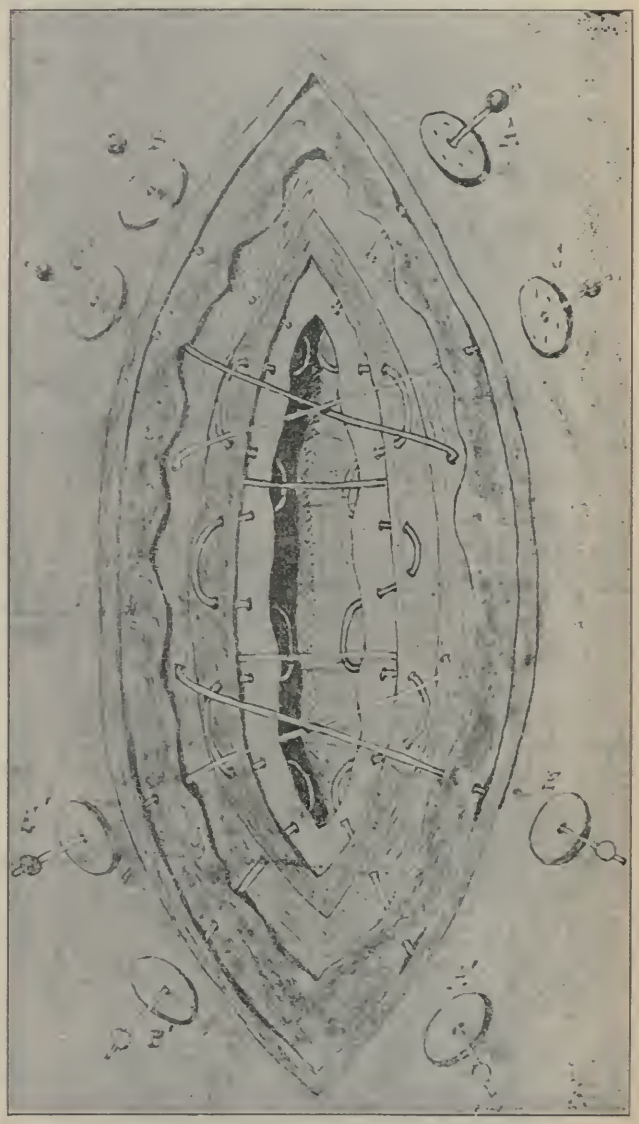

Figure 1.

The next step in this operation is to draw the muscles over the raw surface of the kidney, which is accomplished by passing double silkworm-gut sutures, starting at C, going through skin and fat, crossing over and taking in all of the muscles of opposite side, then recrossing over surface of kidney to take the muscles of the side whence suture started; to be recrossed and take in fat and skin, as shown in Figure 1, C′. The same procedure is followed in lower angle of incision, as shown in Figure 1, E and E′. If necessary, one or two more of this sort of figure-of-eight suture may be made, as shown in Figure 2.

When these figure-of-eight-like sutures are made tense, they serve to draw the muscle edge together and bring

their posterior raw surface in contact with the raw surface of the kidney parenchyma, at the same time bringing the adipose and skin in opposition. The "agraffes" (hooks) of Dr. Michel serve to make linear apposition of the skin, as shown in Figure 3.

The only dressing made is plain sterile gauze with tight-fitting abdominal bandage. The patient is kept

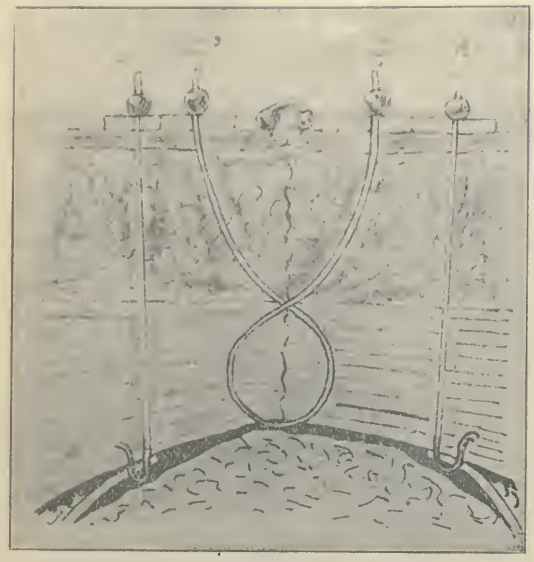

Figure 2.

in dorsal decubitus for about twenty days. The third day the agraffes of Michel are removed and collodion with absorbent cotton applied to skin incision.

On the twelfth to fifteenth day the shot and shield of A and B′, C and E′, are removed, leaving the sutures to loosen by the respiratory movements, so as to avoid

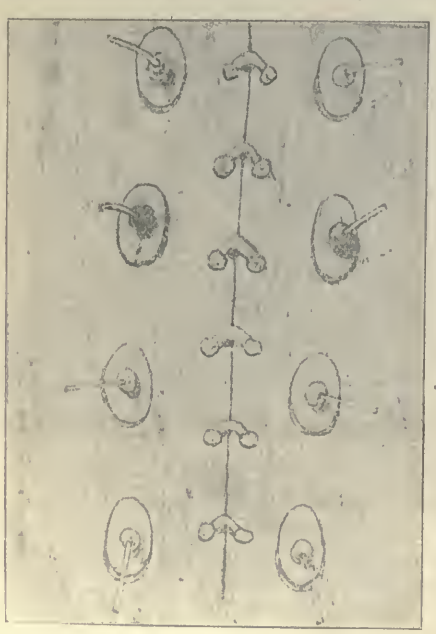

Figure 3.

pain and the possible breaking of the sutures in its final removal, a few days afterward.

By this method, it will be noticed, there are no buried sutures left to serve as a cause for future trouble.

Should there be an excess of oozing, a small strip of gauze may be left for drainage between sutures C and E and removed the second or third day of operation.

Since 1890 I have performed this operation 281 times, following this technic, and have never yet observed a failure. At this time it may serve a useful purpose to remark that in ten cases of double nephrorrhaphy, where, prior to operation, there had existed chronic nephritis and enlarged kidneys, with albumin and granular casts in the urine, in a few months following operation the urine cleared itself of pathologic products, and an evident diminution in the size of the kidneys was apparent, which I attributed to the freeing of the capsule of the kidney and the improved circulation in that organ.

In sixteen cases of single nephrorrhaphy, where the floating kidney was enlarged and congested, the bene-

Figure 4.

ficial effects of the operation were apparent in thirty days and the kidney practically restored to normal in two months following the operation.

TECHNIC OF HERNIOTOMY FOR RADICAL CURE OF HERNIA.

An oblique incision of the skin 5 cm. long is made parallel to the pillars of the inguinal canal. With the finger separate all the cellular tissue until the vas deferens is reached. Gentle traction is now made on the vas deferens, which brings the sac into view, which is usually attached thereto. The sac is now freed from the cord and adjacent structures, and for a distance of 3 cm. around and within the internal abdominal ring.

A curved needle, armed with double silkworm-gut sutures, is inserted at the neck of the sac, following its edge in the entire length of the sac, keeping to the margin, across the fundus and up the opposite edge, making a purse-string suture, as shown in Figure 4,

Figure 5.

C and C′. A second double silkworm-gut suture is now passed through the fundus of the sac, as shown in Figure 4, D and D′.

Now the finger is inserted through the external ring,

Figure 6.

between the peritoneum and abdominal wall. A Doyen's needle is inserted 4 cm. above the pillars and 3 cm. internal, i. e., towards the median line, as shown in A, Figure 4, and passed through skin, fascia and muscles until the finger is reached, and on which it is guided through the wound. Suture C is now threaded to this needle and brought out at A. This same process is followed in A′ by inserting needle 1½ cm. external to A, and on which thread C′ is passed and brought out at A′.

These sutures are now held by forceps. About 3 cm. external to A′ and parallel to it, the Doyen's needle

Figure 7.

is inserted as previously described, and threaded with suture D, and drawn through B; 1½ cm. external to this suture the needle is again inserted as above and threaded with D′ and drawn out at B′. Suture A and A′ are drawn moderately tense and threaded with shields and shot, and shot crushed.

The same process is followed with suture B and B′. It will be readily seen that drawing taut sutures A and A′ and B and B′, the hernial sac is held taut between the

Figure 8.

parietal peritoneum and abdominal wall, making a bulwark above the internal ring, which serves at all times to resist any intra-abdominal pressure.

The cord is replaced in its normal bed and the pillars and abdominal wound carefully closed over it by two

or three figure-of-eight sutures, as described in the technic of nephrorrhaphy and shown in Figure 5.

The final closing of the wound and schematic drawing of the folded sac is shown in Figure 6.

On the third day the Michel hooks are removed and collodion and absorbent cotton applied to the skin incision.

On the tenth to the twelfth day the shot-holding sutures A and B are cut loose, also one end of each of the figure-of-eight sutures are released and left in

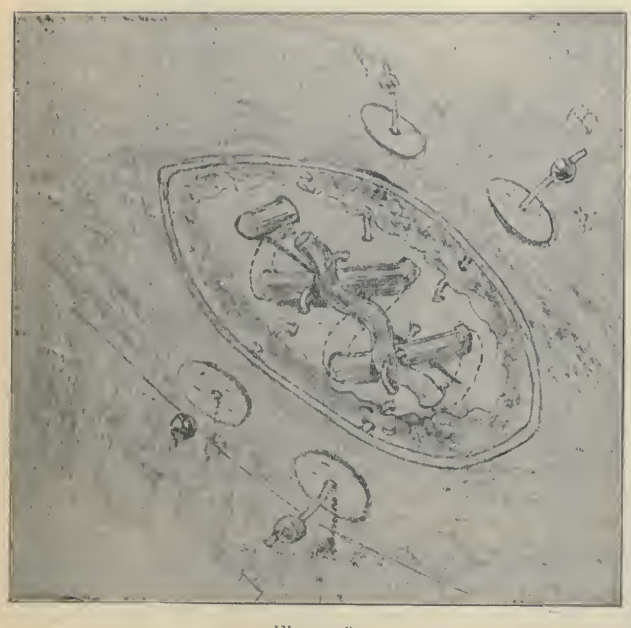

Figure 9.

position for two or three days more, at which time they are easily removed without pain.

Should, at this time, it be found difficult to remove the folded stitch A and A′, a small strip of gauze is wound under the remaining shield so as to form a cushion which will serve to assist the respiratory movements in further freeing the stitch.

In this operation there are no sutures left for absorption or encystment.

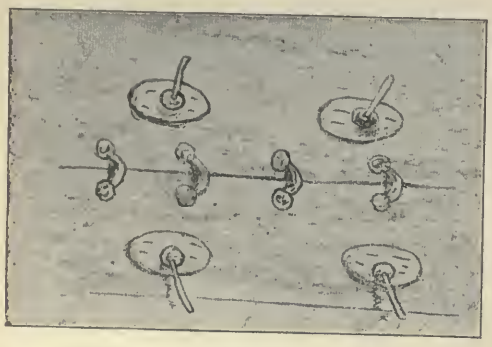

Figure 10.

A NEW MODIFICATION OF ALEXANDER'S OPERATION FOR SHORTENING THE ROUND LIGAMENTS.

An incision of 6 cm. is made over and parallel to the inguinal canal through the skin; with the finger dissect the fatty tissue down to the fascia. With the assistance of a grooved director, perforate the fascia over the inguinal ring. The small bunch of pearly white, fatty tissue, commonly found over the inguinal ring, is picked up, and on the inferior side is found the round ligament. This is now carefully dissected from its peritoneal hood for a space of 10 or 12 cm. A silkworm-gut suture is tied at its distal end. A Deschamp's needle is passed through the fascia and muscle of the inguinal ring about ½ cm. from its edge and threaded with the silkworm-gut suture, as shown in Figure 7.

The round ligament is made to follow this carrier suture and its own structure used as a suture of the inguinal ring. About 2 cm. below, this same method of suturing is followed, as shown in Figure 8. Again, a third suture is made as above. The end of the round ligament is overlapped over the last two round ligament sutures.

These round ligament sutures are anchored in place by silkworm-gut sutures, placed in the following manner: A curved needle, armed with silkworm gut, is passed through the skin and fat and taking a loop of fascia, then passing through the middle of the two crossed round ligaments, dipping again into the fascia and coming through the fat and skin of opposite side, as shown in Figure 9, A and A′. This same process is followed for suture B and B′.

It will be noticed that the inguinal ring and canal will thus be sutured by the round ligament itself and reinforced by its overlapping, which in turn is anchored by a silkworm-gut suture, which, when drawn taut, presses them together and overcomes the necessity of leaving any buried sutures in the wound. These silkworm-gut sutures are threaded with shields and shot, drawn moderately tense and the shot crushed. The Michel hooks are used for the close approximation of the skin edges, and removed the second or third day, and the line of incision covered with collodion and absorbent cotton. In about fifteen days following the operation, shot A and B′ are cut off and the suture left for three or four days more to partly free itself, at which time the sutures may be removed painlessly.

When the round ligaments are illy developed and there is marked uterine retroversion, an assistant is requested to raise the uterus into position by vaginal manipulation.

THE MOSQUITO AS A CARRIER OF DISEASE.

J. STEBBINS KING, M.D.
LATE U. S. ARMY SURGEON IN CUBA.
DECATUR, ILL.

While preparing a paper for the Decatur (Ill.) Medical Society on the "Mosquito as a Carrier of Disease," I was surprised to learn, through the numerous medical journals consulted, that so many of our profession had adopted the extreme, and to me the erroneous, view that the mosquito was the only intermediate host for the transmission of yellow and malarial fevers.

While the various scientific experiments made during the past few years prove conclusively that the mosquito is one great factor in the transmission of these fevers; and that by the extermination of the mosquito, and the proper precautions against allowing this insect to bite those afflicted with these diseases, a great reduction of the number of patients can be made in any community; yet, in my estimation, the evidence does not establish the fact that the mosquito is the only medium through which these fevers can be propagated. Those who maintain that it is claim that the experiments in Cuba, in 1900, of the board for the "Study of the Etiology and Prevention of Yellow Fever," prove the correctness of this, as to yellow fever. It may prove so to those who have not had any practical experience in the treatment and

study of yellow fever during epidemics of that disease; but not to many who have had such experience.

The experiments of the board on which their eighth conclusion, "Yellow fever is not conveyed by fomites, and hence disinfection of articles of clothing, bedding or merchandise, supposedly contaminated by contact with those sick with the disease, is unnecessary," was founded on placing three non-immunes in a small house in which was placed clothing, bedding, etc., contaminated by having been used by persons sick with yellow fever. They slept there twenty nights, then two other non-immunes took their place for the same time, then again two other non-immunes for the same period. A test was made with these seven men from Nov. 30, 1900, to Jan. 31, 1901. As none of these men contracted the disease, the board at once jumped to the conclusion that this forever settled the non-contagious character of yellow fever—hence their eighth conclusion.

This test was totally inadequate. Perhaps had they placed seven other men to the same test they would have had entirely different results. The erratic and uncertain transmission of yellow fever during an epidemic from one part of an infected district to another, striking down some non-immunes, and leaving others who had been equally exposed, should teach us to place but little reliance on so meager experiments as those made by the board. Yet many members of our profession have followed the dictum of the board, as a flock of sheep will follow their leader, even though he takes them over a precipice and dashes them to death; which will be the result to non-immune physicians and their patients, should they, during an epidemic of yellow fever, disregard all the usual precautions of exposure to infected articles and to proper and thorough disinfection.

During my eleven years' residence in the South, and an experience in the study and treatment of yellow fever during three epidemics, of which one lasted from August 15 to December 25, and occasioned 1,375 cases and 125 deaths within the city limits, there were a number of non-immunes who passed through this terrible scourge—taking care of the sick and being bitten by the numerous culex mosquitoes that existed—and yet did not take the disease. Some who did this in the epidemic of 1867 took the disease in the next epidemic, 1871. Every physician who has had an experience with yellow fever during an epidemic can give the same experience.

While I was on duty at Santiago de Cuba as U. S. Army surgeon from July to November, 1898, numerous instances came under my observation of non-immunes being in contact with yellow fever patients, and, of course, at the same time being bitten by the Cuban culex mosquitoes, and yet they did not take the disease. All who are exposed to yellow fever do not take it; which we know to be true of all other infectious and contagious diseases. Hence the eighth conclusion of the board appears almost absurd. Simply because these seven men did not take the disease is no evidence that it can not be taken by exposure to articles contaminated with yellow fever. If the same rule was applied to the mosquito theory it would not stand for a moment, for hundreds of non-immunes are bitten every year by infected culex mosquitoes where yellow fever exists as an epidemic and do not take the disease. Why non-immunes can be exposed for days and months to yellow fever, and that, too, in the presence of infected culex mosquitoes, and not take the disease, is beyond our ken to explain. It is strange how they do it, but they do.

An editorial in The Journal of the American Medical Association, Feb. 23, 1901, well and truly says:

> The experiments of Drs. Reed, Carroll and Agramonte make a great advance in our knowledge of yellow fever. . . . For them to be accepted as conclusive, however, and as overthrowing at once all former notions, is not exactly the scientific course. . . . The facts already obtained must guide us to others. In the meanwhile, it would be foolish to think of neglecting all hitherto accepted safeguards against the disease.

Major Havard, Chief U. S. Surgeon, Division of Cuba, in his report to the Surgeon General, U. S. Army, July 10, 1900, says:

> Our increased experience with yellow fever has shown us that there is much about the nature, development and communicability of the contagion of which we are ignorant. The laws governing this disease have not been discovered. It continues to strike when and where it listeth, regardless of our most reasonable expectations, and best hygienic measures.

The Major is emphatically right in this statement. Therefore, as we do not as yet know the specific cause of yellow fever, nor the numerous and varied means by which it may and can be transmitted, we should continue to use every possible precaution against it in our southern states.

That the mosquito is one great medium for its transmission we know, and we may in the near future learn of other means of its transmission and be able to combat them. That others exist the careful study of epidemics of yellow fever of the past will demonstrate. Its erratic and inexplicable movements in an infected district can not be accounted for on the mosquito theory alone.

As to whether the mosquito is the only intermediate host for the transmission of malarial fever: the majority of our profession are convinced that it is not. We do not know any more about the laws that govern the transmission of malaria than we do of those that relate to yellow fever. We know what the malarial parasite is when developed in the human blood; but what it is outside of that and the laws that govern it are yet unknown. Lavern, a French army surgeon, in 1880, claimed to have discovered the causative micro-organism of malaria outside of the human body, and after further investigations, in connection with a few persons in different parts of the world, decided that it could not be fully developed so as to produce malarial disease in the human being except through the stomach of the anopheles mosquito, and then through the bite of that insect produce malarial fever in the human being. No doubt much, if not the entire, theory of Lavern will soon be bottled up and placed on the dusty shelves in the laboratory of bacteriologists—to keep company with the Sanarelli bacillus.

In the transmission of malarial diseases by the mosquito the same law exists that does in yellow fever. The mosquito must first bite a person afflicted with malarial fever, and then in from eight to twenty days—average time two weeks—she can transmit the disease to a healthy individual. Therefore, from every community some one must go to a place where malarial diseases exist, let the infected mosquitoes bite him, contract the disease, return home, invite the mosquitoes to come and feast on his blood, then send them forth on a biting mission to his neighbors, and thus spread the disease.

Can any one who has studied the history of malarial diseases, or had practical experience in malarial districts, for a moment believe that malarial fever in former times could have thus been transmitted over our

vast prairies, or now in the bottom lands of our rivers and the swamps of the north and the south by the mosquito alone? Most certainly not! Especially when we take into consideration that it is a well-established fact that mosquitoes, as a rule, go but a short distance from their breeding places, sometimes but a few hundred feet—average distance not to exceed half of a mile—and that in olden times, and even now in our swamp regions, the settlements were and are, scattered—often with miles intervening between them—with but little if any communication one with another.

Many of the experiments that have been made by investigators in different parts of the world during the past few years, which are claimed to have established the mosquito as the only intermediate host in the transmission of malarial diseases, were of a similar character to those made by the Cuban board on yellow fever, and are not conclusive. For it is well known that many persons living in malarial districts can be, and are, exposed year after year to every possible means of contracting malarial fever—through the atmosphere, water and the mosquito—and yet remain in perfect health; and that healthy persons from non-malarial districts can spend months where malarial fevers are prevailing—mingling with the sick and being exposed to every possible means of contracting the disease—and not have a symptom of malarial trouble. Thousands of persons living in malarial districts can testify to the truth of this. The writer, who has had years of experience living in malarial districts, both before and since he became a physician, can most positively vouch for the truth of every statement here made.

THE BACTERIOLOGY OF CYSTITIS.*

R. C. LONGFELLOW, M.D.
FOSTORIA, OHIO.

In the light of present advances in the real causes of cystitis, no one who is a student of progressive medicine will or can ignore the foreground bacteriology has taken in cystitis as other diseases, and bacteriologic investigation has proven that all cases of cystitis are due to infection of pathologic bacteria, even though trauma may first be given that organ from internal or external sources. Normal urine is free from all bacteria, whereas urine contained in the bladder under any diseased conditions of the urinary tract must necessarily contain pathologic and non-pathologic bacteria.

In cystitic urine, as a rule, both cocci and bacilli are present; either one may exist in excess of the other, both exist equally or only one form of bacteria be present. Among the cocci present are the *Staphylococcus pyogenes aureus, albus* or *citreus,* the *Micrococcus ureæ, Sarcina urinæ,* the *Uro-bacillus liquefaciens septicus,* the *Streptococcus pyogenes,* the *Zooglœa* masses and the *Gonococcus.* The bacilli are usually the coli communis, the tubercle and in cystitis during the middle or latter end of a typhoid attack the Eberth bacillus. Thiogenic bacteria may be present, whose peculiar function is to convert sulphuretted hydrogen into more potent compounds of sulphur, and play no small rôle in cystitis. The pathologic bacteria that are factors in most cases of cystitis are the colon bacillus, the different varieties of staphylococcus, the streptococcus, the tubercle and the gonococcus. The bacteria may invade the bladder mucosa from the meatus, urethra, or the blood may contain certain bacteria, which is true of pyemic and septicemic infections, and cystitis supervene from these conditions. The bacteria may descend through the ureter directly from the kidney, or penetrate the bladder wall from the intestine, as sometimes occurs, for the colon bacillus has been found in the blood during an attack of enteritis.

Instrumentation may frequently cause infection, even though performed under almost or seeming perfect asepsis. Vulvovaginitis in children, proctitis also, often produce cystitis, due directly to an invasion and infection of the mucosa by the bacteria in the vulvovaginal secretions, aided, perhaps, by the careless hygiene of children and the common habit of titillation of the external parts. The resisting power of the bladder mucosa against bacteria is lessened by any condition producing congestion of the bladder. This is proven by the congestions following contusions or lacerations of the urethra during labor, or after a sudden suppression of the menses from any cause excepting pregnancy. At one time the mucosa may be proof against the infection of bacteria, at another time the condition may be reversed, and an infection from certain bacteria produce an acute cystitis. Urine containing cystin has been considered infectious, during which condition of cystinuria certain bacteria produce a metabolic condition in the mucosa and muscular wall which results in an infiltration or hyperemia to a lesser or greater degree.

In the simple non-suppurative cystitis, caused by non-pathogenic bacteria, the urine is decomposed by these bacteria and produce a condition known as bacteriuria, but do not penetrate the mucosa. The streptococcus does not decompose urea, whereas the staphylococcus in most varieties do, and are present in alkaline urine. The saprogenic bacteria are not factors in the non-suppurative cystitis, and only rarely are present in the suppurative form, then in necrotic conditions. A group of bacteria, saprophytic in action, are the nitrifying and denitrifying bacteria, whose function may later produce ammoniacal urine, or add to it, when caused by other before-named bacteria. When the urine is ammoniacal, the nitrifying bacteria if present, oxydize ammonia into nitrous acid, and under reversed conditions the denitrifying bacteria, if present, convert nitric acid to ammonia and nitrous acid. In cystitis zymogenic bacteria rarely if ever enter into the fermentation process, as they do in beer, wine, butter and cheese manufacture, from whose bacterial action the necessary fermentation must result to produce these domestic articles of commerce. The *Proteus of Hauser* acts decidedly on urea, produces ammoniacal urine and may often be found in such urine caused by other bacteria. The *Proteus vulgaris* is often found in urine and is an important factor in the causation of pyelonephritis, as these bacteria descend with the urine into the bladder and find a host in the mucosa. In the suppurative cystitis the urine, which may be acid from the *Bacillus tuberclosis,* may also contain the *Bacillus coli communis.* Ammoniacal urine may contain other than decomposing bacteria, may contain only the *Bacillus coli communis* due to outside infection, as by instrumentation or other procedures by the patient. When ammoniacal fermentation of urine occurs it is not due to the *Micrococcus ureæ,* but results from the then or pre-existing cystitis in less or greater degree from other bacteria. In ammoniacal urine cystitis to a less or greater degree precedes the ammoniacal condition, oftentimes from the action of thiogenic bacteria on urea, previously mentioned. The acid urine in cystitis is rarely, if ever, caused by instrumentation. In some

* Read by invitation before the Seneca County Medical Society, Tiffin, Ohio, Sept. 18, 1902.

forms of cystitis the alkalinity of the urine is due to certain bacteria which decompose urea, such as the *Bacillus pyocyaneus,* with or without the aid of the *Bacillus coli communis,* and even when the latter bacillus is present in large numbers.

The *Bacillus tuberculosis* plays an important rôle in cystitis, due generally to a secondary infection from pus, as in a tubercular kidney or tuberculosis of the urinary tract. in which the pus infected with the *Bacillus tuberculosis* is washed down through the ureter to the bladder mucosa. Not infrequently an ulcer of tubercular origin gives direct infection to the mucosa at a point remote from the ulcer. Disease of the anus, rectum or colon is often the cause of cystitis, as the pathologic bacteria migrate directly through the bladder wall. Cystitis in children is usually caused by the *Bacillus coli communis;* the invasion announced by pyrexia of an uneven course, followed by frequent, painful urination and the presence of blood more or less in the urine, which is subsequent to the marked vesical tenesmus. The urine voided under these conditions will exhibit mucus, pus cells, epithelial cells, blood cells and the *Bacillus coli communis* in large numbers.

The gonococcus as a primary cause of cystitis is not common, but most frequently produces prostatitis, but when cystitis is caused by gonorrhœa the other bacteria will be found as coexisting with the gonococcus as factors in the causation. The *Streptococcus pyogenes* may invade the bladder from a nearby suppurating process, which is spreading in character, or the *Staphylococcus pyogenes aureus* may, and often does, penetrate the tissue of the bladder from a circumscribed abscess formation or a pocket of pus near the bladder. Ischiorectal abscess has produced cystitis, due to the *Staphylococcus pyogenes aureus,* and the streptococcus was found present also, proving the penetrating powers of the bacilli. A pyosalpinx, or a suppurative peritonitis, pyelitis or a pyelonephritis may liberate the staphylococcus or streptococcus directly into the bladder or urinary tract.

In pregnant and non-pregnant women the vagina and cervix uteri are hosts to many forms of bacteria. Often the secretions contain streptococcus of a saprophytic nature, that become virulent under certain conditions of less resistance by the mucous membrane, migrate into the bladder, lodge in the mucosa and produce a form of cystitis occasionally met in gynecologic practice. In uterine displacement, causing congestion, hyperemia, or even hyperplasia, the *Streptococcus pyogenes,* the *Staphylococcus pyogenes aureus* or *albus* have frequently been found in the vagina, at or near erosions of the cervix, ulcers of the vulva or vaginal wall, which have caused an attack of cystitis. Such a case came to the notice of your essayist last March, which occurred in the practice of Dr. Houseman, Fostoria, who sought a bacteriologic examination of a urine, which disclosed the *Staphylococcus pyogenes aureus, Streptococcus, Bacillus coli communis* in large numbers, from which colonies were started, cultures made and kept alive by transplantation. The growth of the *Bacillus coli communis* from this urine on potato media revealed bacilli of such hearty proportions as to remind one of the "Huntswurst" of the up-to-date sausage factory. That urine also contained *Micrococcus ureæ,* sarcina, tetrads and other cocci.

Now and then, during typhoid fever, a cystitis appears, which is due to the invasion and infection of the Eberth, or *Bacillus typhosus.* Such cases of cystitis occur from the last of the second week to the fourth week of typhoid fever. Occasionally a cystitis will supervene during a relapse of the fever, of short or longer duration, which is due to the renewed activity of the *Bacillus typhosus.*

A new factor in the bacteriologic causation of cystitis is the *Bacillus dysentericus* of Shiga, the Japanese investigator. This bacillus is the cause of that virulent form of dysentery which has attacked our soldiers in the Philippine Islands. This bacillus varies but little from the *Bacillus coli communis* or the *Bacillus typhosus,* and certainly belongs to the colon family. It has been reported as the cause of a severe attack of cystitis supervening the acute attack of dysentery, when the dysentery becomes of a chronic character. As our soldiers return to this country, bringing cases of the acute and chronic tropic dysentery, these bacilli may in the future be added to the long list of "home bugs now doing business at the old stand." In suspected infection of the bladder by the bacillus tubercle it may be necessary to obtain the urine free from contamination from the meatus, urethra or external parts, which can best be accomplished by sterilized catheter under aseptic conditions. The *Bacillus smegmæ* is apt to contaminate the urine and might be mistaken for the *Bacillus tuberculosis.* The same holds true of the *Bacillus Lustgarten,* the so-called bacillus of syphilis and the bacillus of leprosy, but the latter—so rare in this country—is not a factor in pathologic examinations for *Bacillus tuberculosis.* For ulcerative nodular elevations at the urethral orifice, or in the bladder, the differentiation of the *Bacillus tuberculosis* and the *Bacillus Lustgarten* must be made, but the local and constitutional condition will usually be sufficient to decide between the last two if present, and the method of procuring the urine will greatly decide the possibility of contamination of the *Bacillus smegmæ.* The cystoscope is an invaluable aid in the early diagnosis of vesical ulcers, nodules, etc., and catheterization of the ureters in complex cases may be necessary for a differential investigation. The platinum loop or curette may be utilized, scrapings secured of suspected ulcers or nodules, colonies started, if possible, for the culture and staining differentiation in complex or obscure cases.

118 East North Street.

GASTROINTESTINAL PERFORATIONS AND THEIR DIAGNOSIS.

F. GREGORY CONNELL, M.D.
SURGEON TO ST. VINCENT'S HOSPITAL.
LEADVILLE, COLO.

(Concluded from p. 833.)

PRESENT ACCEPTED METHODS. B. EXPLORATORY LAPAROTOMY.

So we see there are but two recognized methods of arriving at a diagnosis of perforation, i. e., awaiting peritonitis or performing laparotomy. The former is unreliable and of little value; the other, while it may be of great value, is of considerable real danger. As to a choice between them the consensus of opinion is in favor of the latter. Fewer cases will die after performing an exploratory laparotomy on all suspected cases than will be lost after awaiting the development of a peritonitis to corroborate the diagnosis. By awaiting the symptoms of a peritonitis in all such cases some few will not develop them and will recover without being exposed to all the dangers of an unnecessary major operation. To perform laparotomy in all such cases will of necessity result in some few being needlessly exposed to the many dangers of a major operation. But in the first instance the chances of a satisfactory outcome are as

small as is the danger of doing an unnecessary operation in the second. Certain cases undoubtedly do recover without operation, after penetrating wounds of the abdominal wall. But the vast majority of such cases are those uncommon instances in which a bullet enters the peritoneal cavity and by pure chance fails to injure the gastrointestinal canal.

Dr. Loomis,[35] in discussing Dr. Fitz's paper, said: "I do not remember to have seen a single recovery after there was unmistakable evidence of intestinal perforation."

Mr. Makins, speaking of gunshot wounds of the small intestine which occurred during the Boer war, says: "In the majority of cases which recovered spontaneously the injury was not of a perforating nature, and that in five cases in which the injury was certainly diagnosed in the hospital death occurred."

Flagg[16] reports a case of penetrating gunshot wound received in the Philippines in which exploratory laparotomy was performed and no perforation found, the patient recovering uneventfully.

Robinson[21] cites a case of penetrating wound of the abdomen on whom laparotomy was performed with no injury to the intestine found. Patient recovered. Such a happy ending is rare and can not be counted on; the probability of nonperforation occurring is not great, for Neff[36] says: "When the diagnosis of perforation is made the viscera will not escape injury in more than 4 or 5 per cent. of the wounds."

So in the absence of any method of definitely determining the true state of affairs it is better to consider all cases as are the 95 per cent. As we do not know which are included in the 5 per cent., we had better disregard the minor per cent. entirely. Cases in which undoubted perforation of the gastrointestinal tract has occurred and recovery followed, without any operative interference, are quite uncommon. The chief method of nature in such cases is by the establishment of an artificial anus, or a fecal fistula. In other cases the difficulty exists in differentiating those cases in which the intestine is injured from those in which it escapes damage; as a rule, in the absence of an autopsy, all cases of recovery following penetrating wounds of the abdominal wall are considered as cases in which the intestine escape injury. In this connection Makins is quoted as saying: "Wounds of the intestinal tract showed themselves capable of spontaneous recovery in a certain proportion of cases." But we are not told how he made a positive diagnosis of perforation in these cases which were not operated on and which recovered.

One of the earliest cases in which undoubted injury to gut was followed by recovery without operation is recorded by Littre in 1705, and is referred to by John Bell in his "A System of Surgery," Edinburgh, 1826. It is the case of a madman who stabbed himself with eighteen wounds in the belly, and of these eight penetrated the abdomen; they were made with a sharp-pointed knife. The fever, pain and swelling and difficult breathing, with vomiting and purging, proved them to be dangerous wounds; vomiting of blood discharged by the stool proved that the wound touched the stomach and the intestine; yet desperate as this case appeared, in two months the man had entirely recovered. His madness came on him again and about eighteen months after he threw himself from a high window and died. On autopsy it was found "that the jejunum just below the stomach had been injured with a cut half an inch in length across the gut; the right side of the colon had been injured with a cut one inch in length, the scar which it left being a half inch long." This is of interest and value in showing to us that it is possible for such a case to recover without surgical intervention. We will not consider the possibility that these scars might be the result of some ulceration from within, probably caused by a foreign body. As the man was insane there is a chance that foreign substances might have been swallowed, or that the wound of the knife might have injured the outer coats of the intestine alone, not including the mucosa, and so not forming a perforating wound; but, granting the explanation given by the author that the scars were the result of stab wounds inflicted eighteen months previous, the question remains, how many such cases would recover under similar treatment and how many similar cases would recover after laparotomy and enterorrhaphy? The fact that such a case may possibly recover without surgical interference does not justify one in allowing others to die without attempting to repair the damage.

Such an outcome is usually explained by the establishment of a localized peritonitis which causes omentum or neighboring loop or loops of the bowel to become attached to the site of the perforation and so occlude the opening, preventing extravasation or extension of the inflammation. Such a favorable termination is uncommon and can not be depended on. It may occur in small punctured wounds (as in experiment No. 10), but the size of the intestinal perforation can not be gauged before seeing it. The size of the penetrating object makes no difference, for a small bullet by burrowing obliquely along the convex border may give rise to an opening of comparatively enormous size.

The stopping up of a perforation by the protrusion of the mucous membrane can not be depended on. In all large wounds it everts and so prevents formation of adhesion to serosa; this protrusion forms a mucous canal connecting the septic lumen of the gut with the free peritoneal cavity. The lumen of this canal may be small, but a large lumen is not necessary to allow of the escape and passage of bacteria.

In gunshot wounds and punctured wounds of the abdominal wall the first indication is to ascertain whether or not the abdominal wall is perforated. It is impossible in many cases to tell whether there is an opening in the peritoneal sac from the apparent course the bullet has taken, or from the symptoms which may develop, such as shock, tenderness or muscular rigidity, for all these may be present and yet there be no opening in the peritoneum.

The method of arriving at a diagnosis of penetration in use by the best authorities to-day consists in making an incision over the wound and following the course of the bullet, the track being in plain sight all the time, till the peritoneum is found to be intact or penetrated, when the wound is treated accordingly, either proceeding and doing a laparotomy or closing the wound.

The older, more common and more dangerous method of probing is still used considerably. The objection to the use of the probe is the danger of forcing infectious matter deeper into the wound or even into the free peritoneal cavity; this, of course, can be done with a surgically clean probe as with one not so. All bullet wounds may be infectious, and hence promiscuous probing will only add to the spread of the infection; and again, it is working in the dark; one can not see where the instrument is being forced and damage may be done. It is often unsatisfactory, as the muscles may contract on the track of a bullet and prevent the passage of a probe. The finger has been proposed as a substi-

tute for the ordinary probe. This animated probe will in many cases be too large and will force and spread infection in the same manner as the other, its only advantage being the addition of the sense of touch, which, of course, will be of considerable moment in many cases.

Caution against too much probing in bullet wounds may be found as early as 1845 by Gibson[37] as follows: "The surgeon should make it a rule, when called to a gunshot wound of the abdomen, to spare the probe and finger as much as possible; such examinations thoughtlessly made can do no good and have been the cause of great mischief." And in 1898, by Senn:[5] "A penetrating wound of the abdomen should never be probed, either for diagnostic or therapeutic purposes." Yet in a recent number of the *Annals of Surgery* we find LeConte reports a gunshot wound of the abdomen in which he says: "And a probe refused to pass beyond the latissimus aponeurosis." In commenting on this case and gunshot wounds in general the same speaker says: "It has been my practice to treat the tract of the bullet as septic until it has proved itself otherwise." We would ask then, why probe?

Other methods have been advocated, such as the injection of hydrogen gas or peroxid of hydrogen into the wounds; if the passage of the gas was obstructed it was supposed that the wound did not communicate with the free cavity, and if, on the other hand, the gas did not cause any distention of the track and met with no obstruction, it was supposed to have passed into the abdominal cavity. But these have been found to be inaccurate and dangerous measures, and so are practically abandoned at the present time.

If the wound is penetrating the probability that damage has been done to the abdominal contents is great; as great as 95 or 96 per cent. by one author. But, on the other hand, we find Makins saying that "unless the intestine was struck in such a direction as to render lateral displacement an impossibility the gut often escaped perforation."

In this connection we call attention to the frequent escape of the intestine from injury in cases of stab wound as compared to gunshot wounds. This may be explained by the comparative slowness of the stab wound which allows the intestines to escape from the path of the knife.

The operation of "Paracentesis Abdominalis," so frequently performed yet never damaging the intestine unless there be adhesions between the visceral and parietal peritoneum, at site of puncture, serves also as an example and tends to strengthen the proposition that, in certain cases, the intestine may get out of the path of even a bullet. But, again showing the differences of opinion, the late Sir William McCormac said: "The bowel is nearly always perforated, feces are extravasated and very frequently there is some other complication as well."

It would seem that in the vast majority of cases evidence of penetration is sufficient provocation for laparotomy. Parke says: "The treatment of penetrating wounds of the abdomen requires exploration." But Senn, as late as 1898, says: "Quite recently the assertion has been made by several prominent surgeons that laparotomy should be performed in all cases where it can be shown that penetration has occurred. It must, however, be admitted that in the absence of serious visceral lesions penetrating wounds of the abdomen are injuries from which the patients are very likely to recover without operative treatment, and that when such patients are subjected to laparotomy death may occur solely in consequence of the operation. Clinical experience and the result of experiment show conclusively that laparotomy should not be performed because a bullet has entered the abdominal cavity, but that its performance should be limited to the treatment of intra-abdominal lesions, which, without operative interference, would tend to destroy life." Hildebrandt, Berlin, at the Congress of German Surgeons, April, 1902, in discussing penetrating wounds of the abdomen and their treatment, says: "When the diagnosis of perforation is made laparotomy should be performed immediately." In other cases he advises expectant treatment, performing the operation only when necessary.

Then there are certain and not uncommon conditions under which we may have perforation of the gastrointestinal tract in which the abdominal wall shows no evidence of penetration or even injury, as ulcerations and contusions. In such cases especially is there a crying need for some method of diagnosis other than those two above enumerated.

With our present aseptic technic exploratory laparotomy is *almost* devoid of danger, so that if no perforation is found in the majority of cases no damage will have been done, or, as Cushing says: "Nevertheless, I believe much less responsibility was associated with an explorative laparotomy than with the risk of neglecting a perforation until signs of peritonitis should occur." Or Richardson, who says: "An objection lies in the possibility of unnecessary operation, for the chagrin is great, though the danger is slight, when the patient has been subject to an unnecessary risk." Scudder,[38] in this connection, says: "Indiscriminate early exploratory operations for diagnosis are to be deprecated; it is certainly better, however, to have operated many times and found no lesions than even once to have neglected operating where it might have saved a life."

But in each and all of these quotations there is a tacit admission that it is a question of choosing between two evils, and all are agreed as to which is the lesser. And the lesser evil is evil because it is not absolutely free from danger. Explorative laparotomy on even perfectly normal individuals is not free from danger. Dr. Keen, at the Denver meeting, challenged any one in the room who believed he could do 100 abdominal sections on well patients even and not have a 2 per cent. mortality, and no one took it up. At the Columbus meeting, when criticised by Dr. Morris, he said: "I am perfectly well aware that several of the best surgeons can show less than 2 per cent. mortality, but I still maintain that in the hands of the average man the mortality will be 2 per cent. or higher."

The use of a local anesthesia reduces but one source of danger; the other possible causes of a fatal termination are still present. It is this mortality rate, small as it is; the knowledge that exploratory laparotomy is not devoid of danger; the fact that an unnecessary laparotomy may terminate fatally, that has led to many attempts at some other method of diagnosis, if not absolutely dangerless, perhaps of less langer.

In an editorial in The Journal A. M. A. we find the following: "Any operation which does not better the condition of the patient must be regarded as a therapeutic error. Progress in the future is likely to depend much more on the discoveries which shall make surgery less necessary than to the opening of new fields for surgical treatment. The advance should be in the direction of limiting these unnecessary and harmful operations, for the wisdom of the surgeon should serve as well

to restrain him from operating as to enable him to operate successfully."

NEW METHODS AND EXPERIMENTS.

A suspected perforation, in a case of typhoid fever occurring in the writer's practice, and the lack of conclusive evidence sufficient to justify an operation, even after the aid of consultation with that master of diagnosis, the late lamented Christian Fenger, led to a train of thought which might be expressed in the following manner:

THE SURGEON'S SOLILOQUY.

To operate or not to operate, that is the question;
Whether it is nobler in the mind to suffer
The slings and arrows of a suspected perforation,
Or to take up the scalpel, against our doubts,
And by exploration—end them.
To cut, to explore and perchance not find a perforation.
Ah, there's the rub. Thus uncertainty does make cowards of us all.
To explore, to cut, to laparotomize;
And by so doing find a perforation, and thus snatch
A human being from an untimely grave.
This is a consummation devoutly to be wished.
To test, to prove, to satisfy oneself,
Without the aid of the uncanny scalpel;
To explore without a celiotomy,
To find a reaction, by the aid of chemics,
That would demonstrate beyond the peradventure of a doubt.
That perforation did exist,
What an advance were that my fellow surgeons.
To test, to prove, to answer questions,
From the *x*-ray hidden,
To explore and lay bare the minutest perforation
By the aid of a reaction
Is a want, and the want has long been keenly felt.

And this, in turn, led to an effort to arrive at a means of diagnosis in cases of suspected perforation without the dangerous procedure of a laparotomy and before the development of peritonitis. The available literature was consulted and a line of experiments mapped out, these experiments to begin with the simpler and more readily discernible chemical reactions and from these on to the more complicated and proportionately more valuable procedures that would include the use of the spectroscope, microspectroscope, the polariscope and all available means that might shed even a ray of light on this problem. But circumstances led the writer far from the facilities of the complete laboratory, with a result that but few experiments were performed, and these of a more simple nature. The results, while not absolutely conclusive thus far, show the possibilities of the modern laboratory when intelligent inquiries are made of it.

The experiments have been, in principle, the injection of filtered air or normal salt solution into the abdominal cavity, the withdrawing of the same and examining it for some substance found normally in the gastrointestinal canal and which is not found in the normal peritoneal cavity. Or, to put it in as few words as possible, if there is a perforation will not a delicate chemical reaction detect it?

When any new method of treatment or diagnosis is presented the first indication is to demonstrate conclusively that no harm or damage will follow its application; the second, that it will accomplish some good.

As to air, if no perforation is present will the injection of filtered air into the peritoneal cavity do any harm? Murphy has demonstrated the innocuousness of nitrogen when injected into a large serous sac, the pleural cavity. Senn claims that no evil effect follows the escape of hydrogen gas from the bowel into the free cavity. G. Kelling[39] has recommended tamponing the abdominal cavity with air in cases of threatened internal hemorrhage, and in his method of celioscopy[40] has still further demonstrated the lack of any bad symptoms following the injection of air into the abdominal cavity. In the writer's experiments, in three instances (Exp. 3, 10 and 5) the abdomens of dogs were filled with filtered air and no evil effects of any description was noted, the distention and tympany disappearing in from two to six hours. On the contrary, in one instance in which the animal was given too much anesthetic and seemed to be about dead, forcible distention of the abdomen with air seemed to resuscitate the animal. Once again, during the same operation, the animal apparently stopped breathing and pulsation of the heart could not be heard. Care was taken to ascertain these facts. Injection of air was again resorted to, with a return of pulse and respiration. A third time the animal collapsed and a repetition of the measure failed to restore him. This was in all probability merely an apparent death, for in two other cases the animal died from the anesthetic, while the injection of air into the abdominal cavity and all other known means failed to bring back life.

On the other hand, if there be a perforation of the gut and examination of the aspirated air reveals the fact, operation will be performed at once.

As to the injection of fluid into the cavity, the normal salt solution is superior to sterile water, in that it does not act as an irritant to the peritoneum and cause the destruction and removal of the endothelial cells as the plain water has proven to do. T. J. Maxwell[41] reports two cases in which he irrigated the abdominal cavity with a normal salt solution, at intervals of from four to six hours, as temperature and pulse indicated, for four or five days, with no evil result as a consequence. Laplace[42] has demonstrated that the peritoneal cavity stands with perfect safety a continuous irrigation with normal salt solution at a temperature of 100 F. during 74 hours.

In the absence of perforation the injection of fluid into the cavity will cause no infectious matter to be spread throughout the sac because there is no infection present. The result of this fluid in the peritoneal cavity will be the same as that which follows transfusion; it will become rapidly absorbed and will act as a stimulant to a flagging circulation and at the same time serve as a most rational treatment for shock and collapse.

If there be a perforation, and examination of the fluid reveals the fact, laparotomy will be instituted at once, and as it is an almost universal practice to flush out the cavity in such cases, this flushing will have been begun before the operation and have acted as a stimulant, so enabling the patient to stand the operation better than without it. By this method no new infectious intestinal contents will be forced into the general cavity, as may occur when the rectal insufflation is practiced. To be sure, the contents which have already escaped may become disseminated throughout the peritoneal sac, but whether it is better for the patient to have 1,000 germs in one locality or one germ each in 1,000 different locations is an open question, regarding which J. G. Clark,[43] who has made a masterly study of the subject, says: "It may appear to some of my readers that the peritoneal infusions of normal salt solution, in cases in which infection is suspected, is to condemn the patient to certain septicemia or even pyemia through the wide distribution of the microörganisms. On the contrary, we believe this very action is prevented." He bases his argument, very rationally it seems, as follows: "Given

a minimum amount of peritoneal infection it is infinitely better to distribute it at once, before the microorganisms undergo manifold sporulation, than to hope for its elimination after it has gained virulent headway through stagnation within the abdominal cavity. By at once distributing a minimum amount of infectious material generally throughout the body the microörganisms are promptly placed in the most favorable situations for their destruction and elimination."

From the above we conclude that the injection of the air or water into the abdominal cavity in the absence of a perforation is harmless, and in the presence of perforation is likewise devoid of danger.

There may be cases of chronic nonperforative peritonitis in which the aspirated air or liquid may reveal substances, contained normally in the lumen of the gut, for Fitz says: "A fecal order may be present in the purulent exudate, which has remained for some time in contact with the large intestine, although there be no perforation on the bowel." And it is a well-known fact that the bacteria, especially the colon bacilli, may pass through the nonperforated intestinal wall.

Cutler and Elliot[21] report a case of typhoid in which the symptoms pointed to a perforation and laparotomy was performed. Peritonitis was evident. No perforation was found, but two grayish patches were almost ready to slough. These were inverted by suture and the patient recovered.

G. Poser and J. Cohn[45] claim, after experiment, that there is no doubt that under certain conditions the intestinal wall is penetrable by bacteria. They injected *Micrococcus prodigiosus* into the rectum of dogs and then sealed the anus. After two days the animals were killed and the prodigiosus was found in the peritoneum. It is probable that a perfectly normal bowel opposes their passage.

This process was called propagation by Monad and Van Vertz.[26] But these conditions are not found in acute abdominal emergencies, and when found in subacute or chronic conditions demand laparotomy as their treatment. To satisfy ourselves that such a condition will not be found in acute nonperforative peritonitis one experiment was carried out as follows:

Large bull dog. Anesthesia, shaved and cleansed. Incision, median line, opening the abdominal cavity. A small piece of gauze saturated with pus from an infected finger was inserted into the cavity and abdominal wound closed. Twelve hours after, when animal showed evidence of peritonitis (tympanites and temperature), normal salt solution was injected and withdrawn. This fluid, on examination for sulphur, ammonia, indol, nitrates, bile, peptone, proteoses, starch, sugar, etc., gave a negative result.

In the first experiments it was our aim to utilize the principle by means of which plumbers locate a leak in the sewerage; that is, by exposing white blotting paper saturated with lead acetate to the suspected air, which, if contaminated with any compound of sulphur, notably H_2S, will convert the lead acetate into lead sulphid and cause the white paper to become black. As the lower bowel at least contains sulphur, and the normal peritoneal cavity contains none, it was hoped that by this means a perforation of that portion of the alimentary tract might be discovered. With this object in view experiments were conducted as follows:

Experiment 1.—Dog. Anesthetized, shaved and cleansed. Abdominal incision, median line. Rectum brought into abdominal wound, which was incised at its convex border for a distance of two inches. The mucosa everted and contents escaped, after which the bowel was returned to peritoneal cavity and the abdominal wound closed. Twenty-four hours after the receipt of injury to gut the dog was found alive, but in very bad condition, tympanites marked. Animal again anesthetized and cleansed. Gas escaped spontaneously from the abdominal cavity after the induction of trocar. This gas was conducted by means of a rubber tube to the bottom of a test tube containing a saturated solution of lead acetate, which solution was turned black in one minute.

Experiment 2.—Dog. Anesthetized, shaved and cleansed. Abdominal incision, median line. Rectum brought into wound and incised on convex border for distance of 1½ inches. Mucosa everted and contents escaped. Injured bowel returned to peritoneum and abdominal wound closed. Twelve hours after receiving the injury the animal was again anesthetized. Two trocars were inserted into abdomen, one below the xiphoid cartilage, and the other above the pubes, and filtered air forced in one trocar. After a slight distension of the abdomen this air made its escape from the second trocar, and upon being conducted to the bottom of a test tube and allowed to bubble through a solution of lead acetate, it shortly turned the lead acetate solution black.

Experiment 3.—Similar to No. 2, and differed only in that the filtered air was forced through the abdomen three hours after the injury instead of twelve hours as in No. 2. The same positive reaction (lead acetate solution turned black) resulted in this case.

Experiment 4.—Similar to No. 3, except that the air after passing through the contaminated peritoneal cavity was allowed to bubble through a solution of iodized starch. As a result this blue solution was changed to a colorless one.

Experiment 5.—Differed from Nos. 3 and 4 in that instead of using lead acetate or iodized starch as a test solution the escaping air was passed through Nessler's reagent, which was promptly turned yellow, indicating the presence of ammonia.

Experiment 6.—To demonstrate that such reactions are not confined to the lower animals, human feces in dilute solution (oz. to pint) of sterilized water were placed in a large bottle and shaken. Filtered air was now forced through this solution and allowed to pass through a solution of lead acetate, which was darkened. The lead solution was replaced by one of iodized starch and this in turn was bleached, and on substituting Nessler's reagent for the starch it was changed to a yellow color.

Experiments 7, 8 and 9.—To exclude the possibility of these reactions occurring after passing the air through a normal peritoneal cavity, and at the same time to determine whether or not there were any evil effects to follow the procedure, the experiments were similar.

Dogs anesthetized, shaved and cleansed. Two trocars inserted, one below xiphoid cartilage, and the other above the pubes. Filtered air was forced through one trocar into abdominal cavity. After slight distension air escaped from second trocar, and was led into a solution of lead acetate, which was unchanged after the air had bubbled through it for five minutes. Similar negative results were noted after the substitution of the iodized starch solution and the Nessler's reagent, for the lead acetate. The trocars were then withdrawn, leaving as much air as possible in the abdominal cavity, and the punctures sealed with collodion. No evil effects were noticed and the next day the tympanites had entirely disappeared, and the animals seemed perfectly normal in every respect.

Experiment 10.—Dog. Anesthetized, shaved and cleansed. Abdominal incision, median line. Jejunum brought into wound and incised for 1½ inches at its convex border. Gut replaced in cavity and abdominal wound closed. Twelve hours after receipt of injury tympanites and peritonitis present. Air was forced through the cavity, and then in turn through lead acetate, iodized starch solution and Nessler's reagent with a negative result in each instance.

Experiment 11.—Dog. Anesthetized, shaved and cleansed. Abdominal incision, median line. Rectum brought into wound. Two trocars inserted into this viscus six inches apart, and air forced through them, the gut being compressed above and below the trocars with Murphy clamps to prevent the air from

filling the entire tube. This air after its escape readily turned the lead solution dark. The same process was repeated in the ascending colon with a like positive result. It was also performed in the small gut, and in the stomach with a negative result. After passing the escaping air through the solution for five minutes no change in color could be detected. The abdominal wall was now saturated with the intention of making tests from the free cavity on the following day, but at that time the animal presented no external evidence of peritonitis, and instead of doing so, rapidly recovered.

This experiment is instructive in demonstrating the necessity of more than one test, as a different substance or substances must be looked for in cases of perforation of the small gut or stomach, and also of extreme interest in proving the possibility of spontaneous healing of the gut and recovery without any attempt at closure of wounds by suture or other artificial means. This animal recovered without suture of gut after receiving eight punctured wounds of the alimentary canal; the wound in each instance being made by a trocar about one-eighth of an inch in diameter. It is worthy of note that in none of these wounds did the mucosa evert, which in all probability accounts for the union and recovery.

While the possibilities of air as a source of information were far from being exhausted, a few tests with liquid were deemed desirable. The observations of Maxwell and Laplace demonstrated conclusively that no evil effect may be expected as a result of the free application of normal salt solution to the peritoneum of human beings, and rendered it useless to prove the proposition on the lower animals. The first experiment was in the nature of a control, the fluid being examined after its passage through a normal peritoneal cavity, one in which the gastrointestinal tract is nonperforated.

EXPERIMENT 12.—Small bull terrier. Anesthetized, shaved and cleansed. Two trocars inserted into the abdominal cavity, one below ensiform cartilage and the other above pubes. One liter of normal salt solution at a temperature of 110 F. was injected into the abdominal cavity, trocars withdrawn and puncture sealed with collodion; after the expiration of one hour, four ounces of fluid were withdrawn from the cavity and immediately examined for ammonia, nitrates, indol, bile, sugar, starch, peptone, proteoses, sulphur, and sulphates, none of which were found, thus showing that with no perforation these substances will not be found in the solution after its passage through a non-perforated peritoneal sac.

Next an attempt to arrive at a diagnosis of perforation of the large gut was undertaken as follows:

EXPERIMENT 13.—Black and tan cur. Anesthesia, shaved and cleansed. Abdominal cavity was filled with normal salt solution 110 F. through two trocars—withdrew about four ounces of this fluid into a bottle marked "Before perforation."

After removing trocars, abdominal incision was made, through which the large bowel was exposed. The rectum was incised on its convex border for a distance of about half an inch and then replaced in its normal location in the abdominal cavity and the wound in belly was closed. Twelve hours after the injury to the gut was received the dog was again anesthetized, the trocars inserted once more and through one normal salt solution introduced into the abdominal cavity, through the other a portion of this fluid was withdrawn and put into a bottle marked "After perforation, twelve hours." Examination of these solutions for ammonia was negative in the first, and positive in the second.

EXPERIMENT 14.—Similar to No. 13, differing only in that the normal salt solution was injected into the abdomen three hours after the injury instead of twelve hours as in the previous one. This fluid was allowed to remain in the abdomen for 30 minutes and then about four ounces of it was withdrawn and placed in receptacle labeled "After perforation, three hours," and which, when examined for ammonia with Nessler's reagent, gave a distinct positive reaction.

EXPERIMENT 15.—Similar to No. 14, except that instead of examining the aspirated fluid for ammonia it was treated with sulphuric acid and sodium nitrate, the change of color indicating the presence of indol. By this test, according to Herter, we are enabled to recognize indol even when diluted as much as one part to two hundred thousand of water.

EXPERIMENT 16.—Similar to No. 15, but instead of examining the fluid for indol it was made alkaline by adding sodium hydroxid and then sodium nitroprussiate was added with a resultant violet color. This indicated the presence of soluble sulphids.

EXPERIMENT 17.—Dog. Anesthetized, shaved and cleansed. Incision, median line. Upper portion of the jejunum brought into the abdominal wound and its convex border incised for an inch and a half. The mucosa everted and contents escaped. Bowel put back. Abdominal wound closed. Six hours after injury, normal salt solution injected into abdominal cavity and after remaining for fifteen minutes four ounces were withdrawn, and examined for peptone or proteoses, bile, sugar, starch, with a negative result for all except the biuret test for proteoses.

EXPERIMENT 18.—Same as No. 17, except that in testing for bile, Hays' reaction was utilized and found positive. When powdered sulphur is sprinkled on a fluid containing bile the sulphur gradually sinks. This reaction, according to Beddard and Pembrey, depends on the presence of bile salts alone, and is still given when one part of bile is diluted by 120,000 parts of water.

TREATMENT.

While it is not intended to include treatment at length in the scope of this paper, the diagnosis and treatment are so intimately related it, it would be incomplete without a few words concerning treatment of the condition when found. The treatment may be arbitrarily divided into treatment of the perforation and of the peritonitis.

Treatment of the Perforation.—As to the perforation, its location relative to the portion of the gut involved will be of considerable importance. The wound may be *a*, at the convex border; *b*, at the mesenteric border, or *c*, between these two. If at the convex border a simple suture will be sufficient. If there is any danger of causing a stenosis the wound may be closed transversely to the long axis of the gut (Heinecke, Mikulicz, the so-called enteroplasty).. If at the mesenteric attachment the blood supply must be carefully studied and in suturing too much blood supply must not be cut off. Some advocate resection, followed by enterorrhaphy, in such perforations. The presence of the mesentery with its separated serous coverings adds to the difficulty of suturing in this locality.

In through-and-through perforations, i. e., with an opening on both sides of the gut, the danger of stenosis is increased, and if near the mesentery the circulation of the convex portion may be imperiled; so it is usually advisable in such cases to perform resection.

The technic of intestinal suturing will not be dwelt on. The Lembert suture is certainly, according to many writers, fast becoming a thing of the past, and the through-and-through suture with the knot in the lumen taking its place.

When resection is necessary a choice lies between anastomosis with the Murphy button and enterorrhaphy with plain needle and thread. The advantage and disadvantage of each can not be dwelt on here, but it seems that the suture method is again gaining popularity.

Treatment of the Peritonitis.—The treatment of the peritonitis, which is unfortunately present in so many cases, is much more unsatisfactory than is that of the perforation. The practice of flushing out the cavity with normal salt solution is almost universal, and the

leaving of a liter of this solution in the cavity is earnestly urged by many.

The use of hydrogen peroxid, as recommended by Morris, has little to recommend it beside the fact that it spreads the infectious material the same as does the use of normal salt solution, and so allows nature to combat the infectious process at many points instead of at one situation.

The bactericidal property of the nascent oxygen can not be great, for if it were sufficient to kill the germs, such as the colon bacillus or streptococci, it would certainly at the same time destroy the sensitive endothelial cells lining the peritoneal sac.

The postural treatment, with elevation of the head, as recommended by J. G. Clark,[46] so aiding in the drainage of the infectious material through the diaphragm and into the mediastinal lymph glands, has many enthusiastic advocates, as has the method with elevation of the foot of the bed, as proposed by G. Ryerson Fowler,[47] which allows the deleterious substances to come in contact with the pelvic peritoneum, which, for some reason, seems more resistant to infection than is that peritoneum at the diaphragmatic portion of the cavity.

The continuous irrigation with the warm normal salt solution for acute general septic peritonitis, was suggested by Laplace[48] in 1889, at which time he said: "The method has not to my knowledge been used before." And at the St. Paul meeting he again refers to it and mentions cases which have recovered following its use.

We find an article by T. J. Maxwell[41] of Keokuk, Iowa, in which he reports two cases of post-operative septic peritonitis treated by free irrigation of the peritoneal cavity as long as the pulse and temperature demanded it.

CONCLUSIONS.

1. The previous attempts at an early and accurate diagnosis of perforation of the gastrointestinal tract without opening the abdominal wall have not been adopted.

2. There has been practically no improvement in the method of diagnosing such conditions during the past century.

3. The treatment of the perforation *per se* during the last century has progressed to a state bordering on perfection when compared with the older methods.

4. The diagnosis of gastrointestinal perforations is one of the most important unsolved questions in the domain of abdominal surgery.

5. There is no pathognomonic sign or symptom or group of signs or symptoms of perforation.

6. The only positive method of arriving at a diagnosis to-day is to either perform an exploratory laparotomy or await the development of a peritonitis.

7. To await the development of a peritonitis will reveal the diagnosis too late for the most effectual treatment.

8. Exploratory laparotomy as a routine measure will of necessity result in some cases being needlessly exposed to the many dangers of a major operation.

9. Exploratory laparotomy is not a harmless procedure.

10. The consensus of opinion is in favor of exploratory laparotomy as a choice between two evils.

11. The fact that even the most expert clinicians fail to diagnose perforation in all cases and even diagnose such a condition when it does not exist shows the great need of improvement in diagnostic methods.

12. The diagnosis should be arrived at before the treatment of the perforation is complicated by the presence of a peritonitis.

13. The injection of air or normal salt solution into the peritoneal cavity and withdrawal of the same for examination will do no harm.

14. Such a procedure will, in many instances, reveal a perforation before any sign or symptom of peritonitis exists.

15. The treatment of the perforation *per se* is simple and satisfactory.

16. The treatment of the complicating peritonitis is multiple and unsatisfactory. The best treatment is prophylactic, i. e., early diagnosis and repair of perforation before peritonitis has become established.

PRIMARY ENDOTHELIOMA OF THE GALL BLADDER.*

WILLHELM BECKER, M.D.

From the Pathological Laboratory of the Milwaukee Medical College.

MILWAUKEE, WIS.

NARRATION OF CASE.

History.—Mrs. R., age 65, referred by Dr. W. F. Malone. Usual diseases of children. Appendicitis three years ago. Full recovery. Thirteen months ago loss of appetite and loss in weight. Family history negative.

Present State.—Weight 52 kilo. Emaciation and weakness very marked. Almost complete anorexia. Dull continuous pain over gastric region; slight tenderness over region of the gall bladder. This is only elicited at intervals. Stiller's sign absent. Abdomen is distended to the utmost in both the gastric and umbilical regions. Ten c.m. below the umbilicus the resonance of percussion takes on a lower pitch. (Percussion from above downward.) No stool the last ten days. Patient

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Pathology and Physiology, and approved for publication by the Executive Committee: Drs. Alfred Stengel, L. Hektoen and Frank B. Wynn.

vomits continually, which consists of a foamy, brownish, malodorous mass, made up of fermenting food remnants. Total absence of HCl free or combined. Presence of an immense number of sarcinæ. No Oppler-Boas bacilli. Stomach is emptied by means of the stomach tube; 1½ liters of fermenting stomach contents are brought forth. Gas evolved by fermentation is CO^2. No lactic acid. After evacuation of the stomach the same is washed with salt solution. Distension over gastric region has now disappeared. The stomach is artificially inflated with air; lower border is found 10½ c.m. below the umbilicus. The partly inflated stomach containing water which is introduced for diagnostic purposes shows the lower border of the stomach 8 c.m. below the umbilicus. Determination by gurgling sound on introduction of air. An attempt to outline the colon by inflation proves too painful and is abandoned. Colonic treatment results in copious stools. Patient feels comfortable. This treatment is continued and the stomach contents are tested daily. After seventh treatment free and combined HCl are evident. Appetite improves and stool every two or three days. All stools contain reduced bile pigments; no blood at any time; never any blood in stomach contents. (Examination according to Weber's method.) In spite of moderately large meals patient continually loses in strength and weight. Percentage of urea ranges from 20 to 28 grams in 24 hours. As soon as a day is allowed to pass without gastric lavage there is rapid accumulation of gas with consequent painful distension of the stomach. This is particularly noticeable when the patient assumes an upright position, or sitting posture. On the seventh day of observation the lower border of the liver is felt for the first time, and a distinct hardening can be felt at the site of the gall bladder. The hardening appears to be in the liver substance. Pressure on this nodular hardening, for instance, on attempting to palpate the gall bladder from below, elicits moderate pain. On distension of the stomach this hardening can not be felt. Never any icterus. Spleen moderately large. The highest total gastric acidity reached was 25, of which 7 were free HCl. After this amount had been reached, the quantity gradually decreased until about two months later it disappeared completely and remained absent until death. Boas' gallstone sign, on pressure pain in region to the right of tenth dorsal vertebræ could not be elicited.

Diagnosis Intra Vitam.—Carcinoma of the gall bladder; kinking of the duodenum; enormous dilatation of the stomach.

AUTOPSY.

In the report of the necropsy only such findings will be mentioned as are considered relevant.

Necropsy was performed six hours after death. Protocol, Dr. M. A. Kleinhans. Abdomen tensely inflated. On opening the peritoneal cavity an enormously dilated stomach tensely filled with gas is evident, which had pushed the colon down into the large pelvis. Only a moderate degree of gastroptosis. On turning the fundus and greater curvature of the stomach upward the gas contained in the stomach can be expelled into the duodenum. The pylorus and duodenum are firmly adherent to the dorsal surface of the liver. The pancreas is, to some extent, enveloped in these gastric adhesions. No gall bladder is visible or tangible. In its stead is a circumscribed firm, slightly elastic hardening in the liver substance. Stomach, liver, pancreas and spleen—which latter is not enlarged—are taken out together. Weights and measures of the organs are all within normal limits except the measurement of the stomach. Serial incisions into the liver reveal an ovoid tumor of white color at the site of the gall bladder. This tumor is directly continuous with the serosa of the stomach and duodenum, and also with the pancreas by means of a slightly elastic tissue bridge. Liver substance shows distinct lobulation, increased periportal connective tissue, especially around the larger bile ducts.

Stomach.—Stomach contains about a half liter of undigested food. The mucosa shows no rugæ. The usual petechia on posterior wall; disseminated plaques of smooth, grayish mucosæ, which are diagnosed and proven by microscopy to be atrophic areas. No bile discoloration of the stomach. No thickening of the mucosa anywhere suggested carcinoma; no ulcers, deep or superficial. Pyloric orifice patent. In the posterior wall of the antrum pylori a hard thickening is seen and felt. It contains crepitating material. The highest point of this elevation is devoid of mucosa. The mucosa is replaced by connective tissue. The thickening is incised, and two gallstones, one the size of a filbert, the other the size of a small pea, are found therein. The gallstones were only slightly facetted and medium hard. The floor of this cavity which contained the stones is formed by the substance of the above mentioned tumor in the liver. The tumor formation had evidently forced the gallstones into their present position. No cystic duct could be made out. Hepatic duct is uninterruptedly continuous with the common duct, and the whole duct is patent. Diffuse fibrosis of the mucosa of this duct. No scar or other mark which might designate the entrance of the former cystic duct. Pancreatic duct is patent and enters the duodenum at 1 c.m. distance from common bile duct. Pancreas moderately sclerosed.

Now, all the length of the intestinal canal is explored, together with the genitalia, uropoietic organs, likewise the contents of the thorax, but no evidence of carcinoma is found.

Heart.—The right ventricle of the heart contained a large marantic thrombus, which had occluded the sinus venosus and branched into the pulmonary artery.

It being a private case, the privilege of opening the cranium was denied.

Anatomic Diagnosis at Time of Autopsy.—Primary carcinoma of the gall bladder; adhesions with pylorus of the stomach, duodenum, and pancreas. Enormous dilatation of the stomach. Cause of death, probably occlusion of the sinus venosus by marantic thrombus. (Patient died with symptoms of apnea.)

After examination microscopically the diagnosis is changed into primary endothelioma of the gall bladder.

DESCRIPTION OF ILLUSTRATIONS.

Pathology.—Figure 1 shows the gross appearance of the tumor located in the lower dorsal aspect of the liver at *a*. The white tumor substance merges gradually into that of the darker liver substance; *b* represents the pylorus and duodenum. The serosa of these two last named organs is seen to be nodularly swollen; *c* shows the increase in the portal connective tissue.

Figure 2 shows the liver and stomach, in order to demonstrate their relative size. It is plainly seen that there is no obstruction of the pylorus, but simply adhesions by means of the serosa. The comparison between the sizes of the two organs, stomach and liver, will at once convey the excessive degree of dilatation of the stomach (*a*). Rosenheim (Krankheiten des Verdauungs-Apparates) states in a differential diagnosis between liver and gastric cancers, that *"Gallenblasen-Carcinome bedingen meist keine Dyspepsie und niemals Ectasie."* A number of authors, including American and French, have, I think, thoughtlessly, repeated this statement. I have seen five cases of carcinoma of the gall bladder during the last year, four of which showed an immense ectasia of the stomach. Figure 3 represents a transverse section through the whole liver, together with an immensely dilated stomach for comparison. In this case, as in the case of endothelioma (Fig. 2), there was no involvement of the mucosa of the stomach whatsoever, and only a slight, easily separable adhesion of the stomach and the under portion of the gall bladder. In one more case of the four that showed signs of dilatation of the stomach during life, I have performed the autopsy which revealed similar conditions as seen in Figure 3. One case is still alive, but since an exploratory laparotomy was performed I had an opportunity to see the dilated stomach in that case. Rosenheim's statement, therefore, can-

not be considered of any value in differential diagnosis between carcinoma of the stomach and gall bladder.

Histology.—A large number of specimens of tissues of all regions were examined. The liver tissue remote from the tumor shows a moderate degree of increase of the periportal connective tissue with new formation of bile ducts. This suggests interstitial hepatitis. The connective tissue, however, does nowhere invade the lobules proper. Study of the individual liver cells shows them to be fairly normal. Epithelium of the old and new formed bile ducts shows no tendency to atypical proliferation anywhere. The connective tissue immediately

Fig. 1.—Vertical section through liver. *a.* Endothelioma. *b.* Pylorus. *c.* Pericholangitis.

surrounding them is in active proliferation (pericholangitis).

In Figure 4 the margin of the tumor is made up of connective tissue containing foci of round cell proliferation (*a*). The individual liver cells surrounded by this connective tissue formation (*b*) are entirely normal. The blood capillaries of this liver tissue are slightly overdistended. This congestion is thought to be due to prolonged agony.

Figure 5, from a section taken about 1½ c.m. away from the margin toward the center of the tumor, also shows mostly connective tissue, young and old, but containing strings of polymorphous large cells, the cytoplasm of which takes a deep eosin stain. In some areas these cells are seen to rise from oblong spaces or narrow slits, which I take to be lymph spaces. Where there is a large number of these cells, those marginally situated seem to undergo gradual fibrillation, and it is then extremely hard to make out the dividing line between the connective tissue proper and the tumor cells.

Fig. 2.—Endothelioma of the gall bladder, with dilatation of the stomach. *a.* Pylorus. *b.* Endothelioma.

The cells contained in the center of the larger aggregations undergo hyaline degeneration. No karyorrhexis; no vacuolization. In other areas the centrally located cells of the cluster seem to lose their cytoplasm and then resemble common small lymphocytes. The change of the cells, or decrease in the size of the cells from the margin toward the center of the cluster, is extremely gradual. Necrosis described by Adler in his paper on "Endothelioma of the Pleura" was not found in this case.

Fig. 3.—Cancer of the gall bladder, with enormous dilatation of the stomach. Adhesion to skin.

The serosa of the stomach and duodenum affords a better opportunity to study these cells as following the course of the lymph spaces. Extensive serial sections were made.

Figure 6 shows a section through the serosa and muscularis of the pylorus (low power). The thickened serosa extends from *a* to *a*. Within it can be seen strings

of the above described polymorphous cells surrounded by a rather voluminous connective tissue stroma. This connective tissue stroma contains numerous foci of round cell proliferation.

Figure 7 shows an area of the serosa under higher power; *a* represents a string of endothelial cells cut

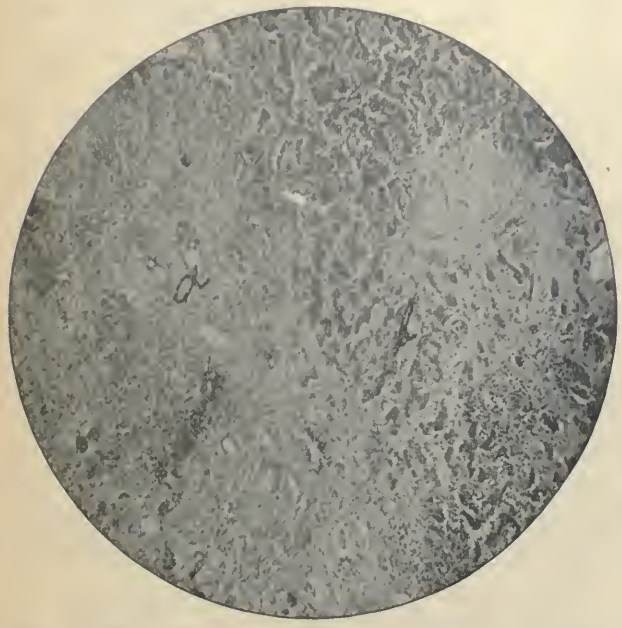

Fig. 4.—Hem. Eosin. Leitz, obj. 3. Section from margin of primary tumor. *a.* Connective tissue (inflammatory). *b.* Liver cells.

longitudinally; *b*, a similar string cut transversely; *c*, an irregularly branching cluster of endothelioma cells. The stroma is seen to contain numerous young connective tissue cells.

Figure 8 is a section prepared from the above-mentioned tissue bridge between the gall bladder and the

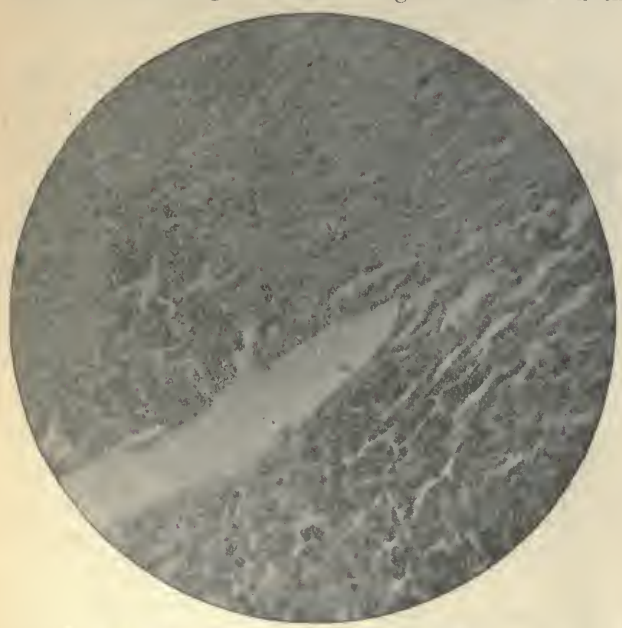

Fig. 5.—Hem. Eosin. Leitz, obj. 6. Section of tumor about 1½ c.m. inwardly from margin of primary tumor. Shows fibrillation of older tumor cells.

pylorus and duodenum. It shows exactly the same structure as does the center of the primary tumor; *a* represents the center of a large endothelial cell cluster. Distinct fibrillation of the endothelial cells at the margin of the cluster.

Figure 9 shows the cluster of tumor cells in serosa of the duodenum. The nuclei of the cells seem to be swollen (vesicular), the chromatin filaments stain distinctly; at *c* is cell with giant nuclei. Numbers of these giant cells, and also polynuclear giant cells were observed. There are a great number of cells which showed degen-

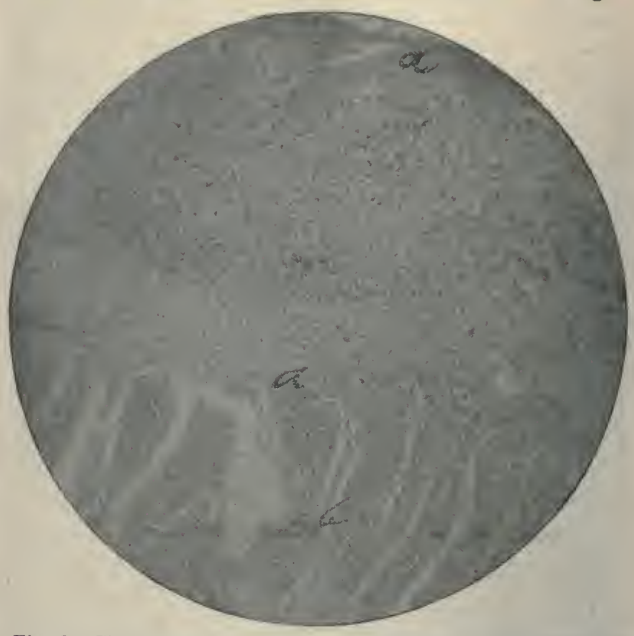

Fig. 6.—Hem. Eosin. Leitz. obj. 3. Section through serosa and muscularis of duodenum. *a-a.* Serosa. *b.* Muscularis.

erative coalescence of several nuclei, thus forming a long, sometimes semi-circular, sausage-shaped nucleus. At *a* and *b* atypical mitoses, of which all varieties were present. Abortive mitoses, clumping of the chromosomes were especially frequent.

Figure 10 is taken from the same slide as Figure 9.

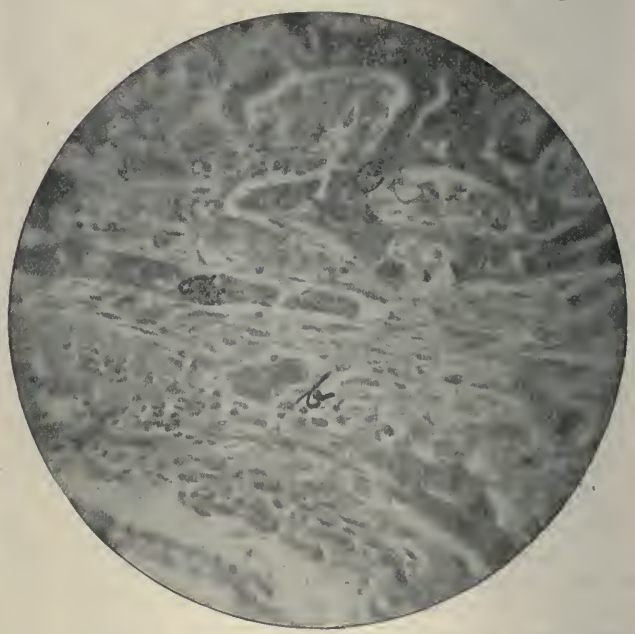

Fig. 7.—Hem. Eosin. Leitz, obj. 7. Area from Fig. 6 under higher power. *a-b-c.* Strings of endothelial cells.

In the center a cell is visible with a giant nucleus; in the cytoplasm a dead polymorphonuclear leucocyte. The nucleus of this leucocyte is undergoing karyolysis, the cytoplasm of the leucocyte is represented by a light ring around the fading semi-circular nucleus. Many in-

clusions similar to this one, with all gradations of degeneration, were observed. (Russell-Plimmer-Leyden-Schueller's Bodies.*)

In the lymph spaces, dilated excessively, the polymorphous "tumor cells" seemed to be suspended in the serous fluid (Fig. 8, *a*). An attempt was made to determine the chemical nature of this fluid in the fresh condition, but, owing to the small quantity obtainable, the attempt was unsuccessful. This much, however, was ascertained: The fluid did not contain any mucin; it may have contained pseudomucin, such as is found in numerous connective tissue tumors, but it was not viscid enough to consist entirely of this substance, or contain a great deal thereof. It did not ferment when brought in contact with yeast cells. It gave the reaction of albumin. The presence of small, round cells, scattered promiscuously through the polymorphous elements, suggested the interpretation of the fluid as lymph. (?)

DETERMINATION OF THE CHARACTER OF THE GROWTH.

These microscopic findings being incompatible with the diagnosis of carcinoma, and agreeing in every detail

Fig. 8.—Hem. Eosin. Leitz, obj. 3.—Section of tissue bridge between liver and duodenum and stomach. *a*. Center of dilated lymph space filled with endothelial cells. *b*. Fibrillation of peripheral cells.

with the histopathology of endothelioma, the latter diagnosis was held as the correct one. Endotheliomata have been described by a great number of authors, and under a multitude of names, endothelial cancer, perithelioma, alveolar sarcoma, sarco-carcinoma, etc. I am not inclined to enter into the nomenclature of the subject, since that would lead to an almost endless discussion. A group of investigators believing the nature of endothelioma to be entirely or partly inflammatory, have proposed names like lymphangitis proliferans, and to convey also the neoplastic idea, lymphangitis carcinomatoides. One thing is certain, that a large number of sarcomata of organoid structure have been described as endotheliomata, which were common angiosarcomata, peritheliomata or hemangioendotheliomata. I do not see the necessity of classifying these tumors as endotheliomata, since we know that the majority of sarcomata originate from the perithelium or endothelium of the blood vessels anyway.

* With apologies to those discoverers whose names have not been mentioned.

Morphologic peculiarities are no criterion for the classification of tumors. This is shown by the confusion brought into the subject of endothelioma by the morphologic classification suggested by Hanseman.

If we, however, reserve the name of endothelioma exclusively to those neoplasms which are the result of an

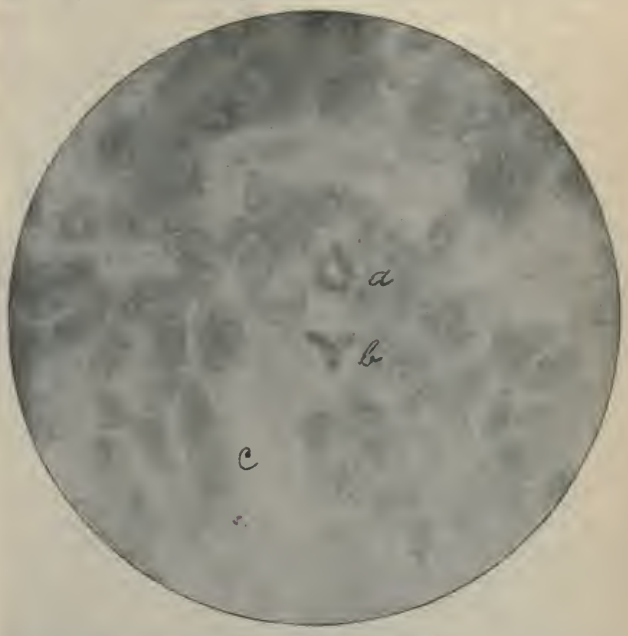

Fig. 9.—From center of alveolus in serosa of duodenum. *a*. Asymmetrical mitosis. *b*. Atypical, tripolar mitosis. *c*. Endothelial cells with giant nucleus. Suffranin. Leitz, 1/12.

abnormal proliferation of the endothelium lining the lymph spaces and serous cavities, we have well-characterized, clear-cut tumors.

That the name of lymphangitis proliferans is also justifiable will be shown below, for I think the inflammatory character of the tumor which I have described

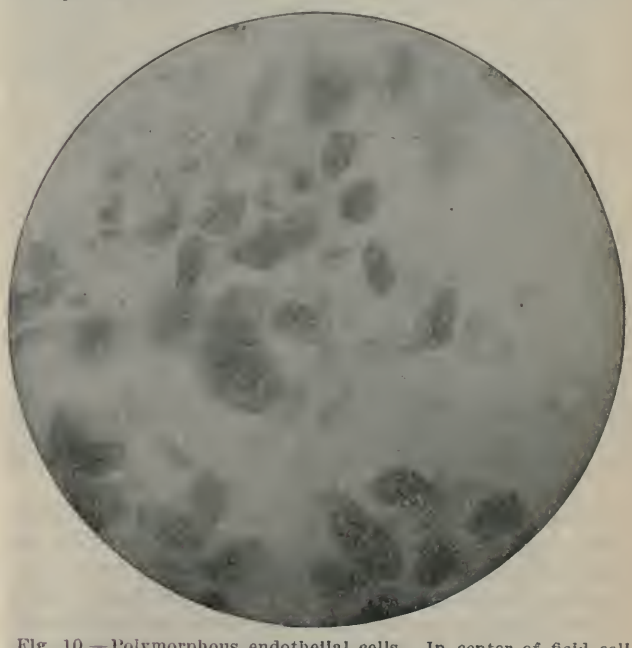

Fig. 10.—Polymorphous endothelial cells. In center of field cell with giant nucleus containing a leucocyte. Saffranin. Leitz, 1/12.

can not be questioned, at least the primum movens of the proliferation of the endothelial cells is of a nature the same as that found in chronic inflammations.

In a number of endotheliomata which I had the opportunity to study, I have never seen any endothelial

proliferation in the lymph spaces unless the surrounding tissue was also in a state of inflammatory hypertrophy. This observation is adduced by Neelsen as an argument in favor of the inflammatory character of the new growth. In addition to this one can easily see that the filling up with cells of the lymph spaces is not the result of an invasion of cells, as we see it in carcinoma and sarcoma, where the elements first get into places not their legitimate habitat, proliferate, and then destroy the surrounding tissue. In the true endothelioma there is first a swelling of the resident cells due to irritation (Reiz Anschwellung, Pollman), most likely of chemical nature, perhaps a cellular poison as described by Ehrlich. Thereafter the proliferation again of these same resident cells takes place in answer to the same formative irritation; dilatation of the lymph space follows. It is evident that the differentiation of the endothelial cells will be lost, or will at least suffer through this onslaught, and anaplasia will result. But this anaplasia may run through "physiologic" gradations. The highly differentiated mesodermic endothelial cells will change into connective tissue cells of a lower type, and will share the fate of all common connective tissue cells. They will fibrillate. This is shown strikingly in Figure 5. The older cells undergo fibrillation first, namely, those seen along the margin of the dilated spaces. Being remote from the lymph current they are deprived of an opportunity to perform their function, even if they were able to perform it; as a result, the cells resign themselves to the quiescent state of fibrillation. This is incompatible with anaplastic, blastomatous carcinoma or sarcoma cells, but is known as the routine process in inflammatory scar tissue formation, i. e., the cells do not maintain the blastomatous character of malignant cells.

The regional expansion of the process may be explained thus: The primary formative irritant was furnished by the presence of the gallstones in the gall bladder, perhaps with an addition of micro-organisms (which were not found). Or there may have been at first an inflammatory occlusion of the cystic duct. The lymphatics of the gall bladder had to remove the altered contents of the same. The change in the chemism of the substance carried by the lymph spaces caused the inflammatory changes of the lining epithelium, as described above.

The cells thus vitiated secreted in turn a vitiated substance which acted as the formative irritant to the adjoining still normal endothelial cells. In this method a circulus vitiosus is established. Experimental pathology and physiology may be able to prove these ideas some day.

Other retrogressive metamorphoses described in connection with endotheliomata, as myxomatous, and especially hyaline degeneration, are likewise frequently found in other common chronic inflammation, viz., in certain forms of peritonitides, zuckerguss exudates, etc., and in a great number of so-called benign tumors.

Furthermore, there is not an area in the tumor where there is not common inflammatory tissue surounding the tumor cells proper, no matter how few they may be in number. Even in the extreme ends of the tumor where the endothelial cells are simply swollen and not multiplied, there is lively inflammation in the surrounding connective tissue. This, also, is unlike the peripheral growth of both carcinoma and sarcoma. We see a round cell sarcoma invade the normal muscular structures, a carcinoma metastasis in a normal lymph node, etc. Specimens stained with Sudan 3 (Formalin-freezing sections) showed numerous endothelial cells containing fat droplets. These are most likely the "vacuoles" found and described in hardened specimens of endothelioma by Adler and others. The significance of these fat drops is not easily explained. Thoma has found that the covering endothelium of the serous surfaces absorbs albumin contained therein into fat. It may be that such a process went on in this endothelioma. The cells certainly do not show any fatty degeneration, but that there is an energetic metabolism going on in the cells is shown by the presence of the serous exudate filling and dilating the affected lymph space (Fig. 8, *a*). I can not believe that this liquid is a simple transudate since there was only an inconsiderable quantity of fluid in the free peritoneal cavity.

METASTASES.

In the tumor here described there was no metastasis; in two more which came under my observation, one of the peritoneum (Dr. E. F. Fish's case), and another of the skin, they were likewise absent. The cases reported in the literature of the last twenty years show about 50 per cent. with metastasis, but I have noticed in the illustrations that a number of these appear like common angio-sarcomata, i. e., the tumor cells are not found restricted to the lymph spaces. Neelsen, who described a number of endotheliomata, lays especial stress on the fact that the cells proliferate *in loco* and do not immigrate. But he has metastases. Wagner could not find any secondary tumors in a woman of 69, where all the tumor cells were within the lymph spaces. In a great many cases the metastatic tumors were found in the vicinity of the primary one; in these instances it is doubtful whether there was not a contiguous growth, as not one report mentions reconstruction methods as a means of ascertaining true metastases. Age and sex do not seem to affect the frequency of occurrence of endothelioma.

Hereditary influence has not been proven in man. Eberth-Spude have seen endothelioma in several members of a family of white mice. Transplantation has been unsuccessful.

OTHER CONCLUSIONS.

Endothelioma, hemangio-endothelioma and perithelioma may be blastogenetically alike, but the first tumor differs materially from the last two in the mode of growth, histology and clinical aspect. One need but think of the functional difference of the normal elements to appreciate this fact.

Endotheliomata are only relatively malignant. A great number of tumors reported under this name are essentially inflammatory.

THE OPERATIVE TREATMENT OF CYSTOCELE AND PROCIDENTIA UTERI.

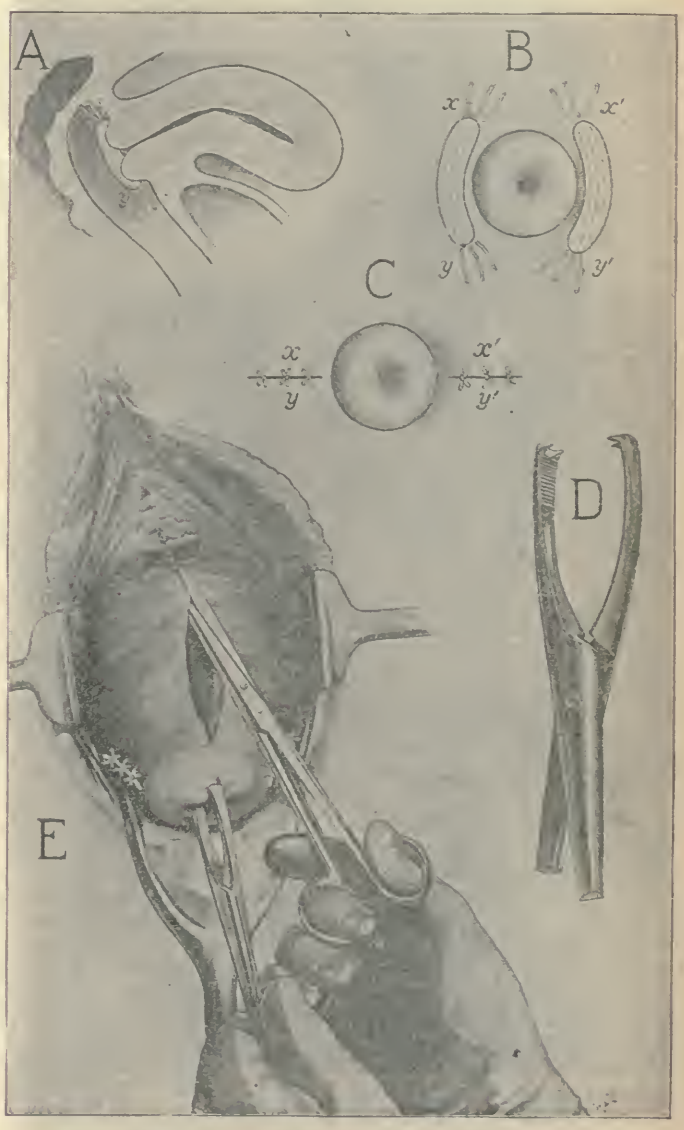
E. C. DUDLEY, M.D.
CHICAGO.

The evolution of the operative treatment of cystocele and rectocele with resultant procidentia includes the following essential factors:

1. Operations of superficial denudation and reefing of the anterior vaginal wall as practiced by Sims and Emmet.

2. Operations on the lateral vaginal walls with superficial denudation, as described by myself and others.

3. The recognition of the essential fact that no operation can succeed that does not include plastic work on the lateral and anterior vaginal fornices with the definite purpose of forcing the cervix uteri back to its normal location in the hollow of the sacrum.

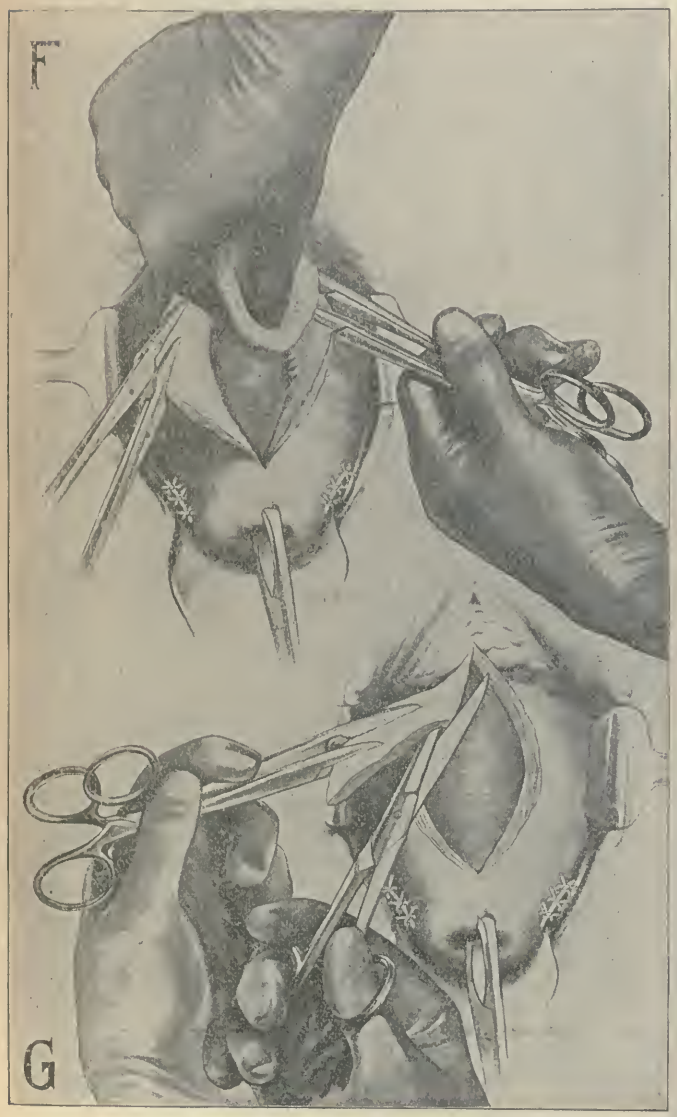


All these measures have been employed with varying success, the variation being dependent on the ability of the operator to force the cervix uteri back into the hollow of the sacrum and to make it stay there. This location for the cervix is the prime indication. With the cervix uteri in its normal posterior location, the corpus uteri must necessarily fall forward into its natural position of anteversion.

The methods above outlined, even though supplemented by hysterorrhaphy, have so frequently failed to give permanent results that many surgeons advocate the more radical alternative of hysterectomy. Of late, however, the essential principles and indications on which successful plastic work may be done are becoming more clearly defined. Dr. Edward Reynolds[1] of Boston sets forth two anatomic points which in the previous literature have not been very clearly brought out, but which necessarily underlie the success of this class of operations. They are: 1. That cystocele is hernia of the bladder and should not be treated by superficially denuding and reefing in the overstretched portion of the vaginal wall, but that this overstretched portion should be removed and the lateral margins of it should be united by interrupted sutures. In other words, this hernia should be treated like other similar conditions by reduction and the excision of the sac so as to expose and unite the strong, fixed facial margins of the wound. 2. A successful operation must recognize two fixed points of attachment of the anterior vaginal wall; the first at its lower extremity to the inner surface of the pubes; the second at its upper extremity to the facial structures on either side of the uterus, which are in direct connection with the broad ligaments. Accordingly, I have made radical changes in my method of elytrorrhaphy for the correction of cystocele and procidentia uteri. The modified operation which I have performed several times with most gratifying results may be divided into two steps, and is briefly as follows:

1. A crescentic denudation and suturing in the vaginal wall on each side of the cervix uteri.

2. The removal of a portion of the anterior vaginal wall and suturing together of the wound thus made.



First Step.—The first part of the operation is performed preferably with the patient in Sims' latero-prone

position and the vagina exposed by means of Sims' speculum. The blade of the speculum should be perforated at the extreme end. Before the speculum is introduced the cervix should be attached to the end of the blade by means of a temporary suture which is passed through the posterior lip of the cervix and the perforation in the speculum and tied. This suture should remain in place throughout the first step of operation. The object of this temporary stitch is to hold the cervix uteri far back in the hollow of the sacrum while the sutures are being secured which shall fix it there. When the cervix is thus held back the space anterior to the cervix is so increased

1. An epoch making paper on this subject has recently appeared from the pen of Dr. Edward Reynolds, American Medicine, Aug. 2, 1902.

that the corpus readily falls forward into a position of decided anteversion; that is, into the normal position. It is essential that this part of the operation be performed with the organ in normal position, because if so performed the result is more likely to be permanent. Two semi-circular strips are denuded in the vaginal wall close to the uterus about one-half of an inch wide on either side of the cervix, their convexity being turned toward the cervix. This denudation is shown in Figure B, *x y* and *x' y'*. This denuded surface is shown on one side of the cervix in Figure A, *x y*. Each denuded surface is now closed on itself by means of fine chromic

catgut sutures, Figures A, B and C. A and B show the sutures in place, but not tied; C shows them tied and also the lines of union running laterally from either side of the cervix. The folding of these denuded surfaces on themselves causes their lower extremities *y* and *y'* to be brought in contact with their upper extremities *x* and *x'*, Figures A, B and C. By this means the cervix is lifted upward and backward toward the hollow of the sacrum and held there.

SECOND STEP.—The second step in the operation is performed with the patient in the dorsal position, the parts being exposed by means of a Sims speculum or a Simon retractor. The operation is now continued as shown in Figure E, then in Figures F and G, then in Figures 1 and 2. Figure E shows the lines of union lateral to the cervix uteri made in the first step of the operation and shows the incision being made by sharp-pointed scissors through the vaginal wall, but not including the vesical wall, from a point near the cervix uteri in the median line of the vagina to a point near the meatus urinarius. The dotted lines in Figure E indicate the extent of this median incision. While the incision is being made the cervix is held securely in place by means of flat vulsellum forceps, a full-size section of which is shown in Figure D. Figure F shows the

Figure 1.

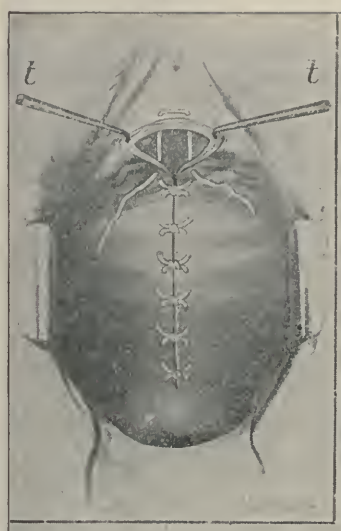


Figure 2.

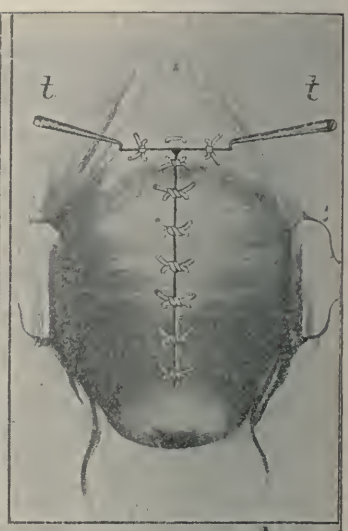

Figure 3.

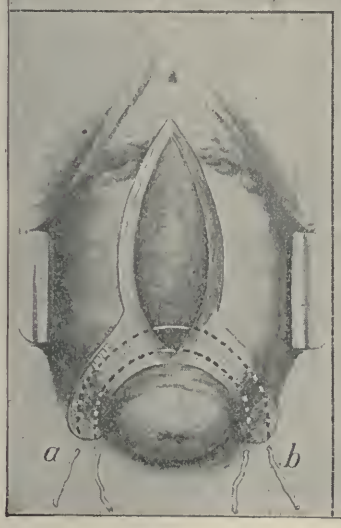

Figure 4.

vaginal wall being stripped off from the vesical wall. The operator has seized the margins of the flap in pressure forceps and is stripping it away from the vesical wall by sponge pressure. This will be found a very effective method of blunt dissection. The flap on the opposite side is held in pressure forceps and is represented as already stripped off. In Figure G the loose flap has been removed by means of scissors from one side and is being removed from the other side. Figure 1 shows the median vaginal wound nearly closed by means of chromic catgut sutures. Experience in this operation has shown that in the majority of cases there is considerable redundant vaginal wall in the region of the

urethra which may be disposed of most effectively by uniting the wound in a transverse direction. Accordingly the lateral margins of the wound are shown as being drawn apart by tenacula, *t. t.* A single stitch introduced but not tied shows how this portion of the would should be united. Figure 2 shows all sutures introduced and the operation complete. The tenacula are the same as shown in the previous figure.

It is extremely essential in this operation that the entire thickness of the vaginal plate of the vesico-vaginal septum be removed, as shown in Figure G. The former method of merely denuding a superficial surface is ineffective. It is unnecessary to add that this operation should always be supplemented by a perineorrhaphy.

Figures 3 and 4 are here introduced to show a method of denuding and introducing sutures so as to force the cervix uteri back into the hollow of the sacrum. This method is offered as a substitute for the one shown in Figures A, B and C, and will be found most applicable to cases of extreme relaxation of the pelvic floor. In principle it is the same as that employed many years ago by Sims, Emmet and others. Figure 3 shows a circular denudation in front of the uterus extending on either side to the post-vaginal fornix. Two sutures are shown in place but not tied. Three sutures are generally used instead of two. These sutures, when tied, will draw the loose vaginal tissues on either side of the cervix to the front of it so as to bring points *a* and *b* together in front of the cervix, as shown by Figure 4, *a, b.* The structures thus brought in front of the cervix uteri are in close relation with the broad ligaments; hence the effect is to bring the lower margins of these ligaments to the front of the cervix and so to force the cervix upward and backward. Reynolds prefers to expose the lower margins of the ligament and to introduce the sutures directly through them. In Figure 4 a threaded needle is being introduced to complete the closure of the median vaginal wound. This part of the operation is the same as in Figs. 1 and 2.

The accompanying figures show the cervix drawn well down to the vulva. This is not in accordance with the fact. The cervix, as already explained, is held well back in the hollow of the sacrum during the operation. The appearance of drawing the cervix downward to the vulva is only introduced to facilitate illustration.

PROGRESSIVE BULBAR PARALYSIS.*

ALFRED C. COTTON, A.M., M.D.
CHICAGO.

Kitty M., aged 11 years, an American schoolgirl, first came to my clinic Jan. 17, 1902.

Family History.—Mother living and well; father died of pneumonia; she has four brothers and sisters in good health; both maternal grandparents lived to old age; her paternal grandmother developed some form of paralysis after childbirth. Her paternal grandfather was paralyzed late in life, and had some disturbance of speech which passed away before death.

Previous History.—Birth and early history negative except for the usual diseases of infancy. She had pneumonia when six years of age; diphtheria three years ago and again last April (1901) from which she apparently made a good recovery. For the past two or three years the mother has noticed more or less impairment of hearing.

Present Illness.—Early in September the mother detected slight difficulty in swallowing and some defect in the child's speech; it seemed as if there were something in the mouth. About the middle of September she was sent home from school with instructions to have her eyes tested. This was done and she was given glasses for astigmatism.

Drooling and speech defects led to a consultation with a throat specialist, who advised the removal of postnasal adenoids. The operation was performed about the 1st of October. She had occasional fits of obstinacy and cried frequently, i. e., she was emotional, but showed no evidence of impaired mentality. Speech and deglutition became increasingly difficult, so that the hand was occasionally employed to retain food in the mouth.

Examination.—A girl of average size for her age, but somewhat pale and poorly nourished. The expressionless face, fallen lip and drooling mouth first arrest attention. She answers questions indistinctly and laboriously; the speech defect shows inability to pronounce labials and denti-linguals; she can not wrinkle the forehead, elevate the eyebrows, close the eyes completely, purse the lips or smile; the tongue can not be protruded beyond the teeth or raised to the roof of the mouth; it is thickly coated, plainly shriveled and lies passively in the floor of the mouth with occasional flickering tremors. The pharynx presents no gross lesions, but the uvula and palate show some anesthesia; the voice is monotonous and of nasal quality; the mouth is full of saliva which pours over the pendulous lip; the child masticates food slowly and swallows with marked difficulty, at times choking and coughing. Fluids do not regurgitate through the nose, nor is there any history of this symptom. The respiration is shallow and under excitement or exertion becomes slightly snoring; she also snores while asleep.

The examination of the ocular fundus and ear by Professor Hotz gave negative results. Pupillary reflex normal. The range of ocular movements is somewhat restricted toward the right. Slight horizontal nystagmus is at times noticeable. She can not close the eyes completely, prolonged effort causing parallel deflection upward and to the left. Eyes are constantly suffused, and there is conjunctival anesthesia. The general muscular system shows but little wasting. Patellar reflexes normal and co-ordination good. Electrical response to both galvanism and faradism normal, with the exception of the facial muscles, which show reaction of degeneration. A. O. C.= 2.5 M. A., C. C. C.=4.5 M. A., A. C. C.=4.5 to 5 M.A. There is no response to faradism (the strongest current) in the facial muscles. (Tested by G. W. Hall, M.D.) No anesthetic areas, either thermal or tactile, were found except on palate and conjunctiva. No tremors were present, except occasional fibrillary twitchings of tongue and facial muscles. Taste as far as observed is not affected. Chest examination negative with exception of systolic murmur; abdomen negative; urine negative.

Subsequent History.—The child was under observation during the last weeks of her life, during which time inanition was steadily progressive, with loss of weight. Towards the last she showed increasing somnolency, disinclination to exertion, and staggering, uncertain gait. Impairment of speech, deglutition and tongue movements increased. In the last two weeks fluids were regurgitated through the nose. A few days before death she developed a slight bronchitis with some elevation of temperature (103).

Throughout the observation until the last weeks the highest temperature was 100.4, the lowest 97, with a tendency to be subnormal. The pulse ranged from 70 to 120 and was easily disturbed; respiration, 20 to 26.

She died rather suddenly the night of April 7, 1902.

Bulbar paralysis is certainly so rare a disease among children that no apology is needed for bringing it to your attention. As you will recall, this disease was described for the first time in 1860 by Duchenne, and it was not until ten years later that the real seat of the lesion was recognized by Charcot and Leyden.

The fact that the symptom-complex of glosso-labio-laryngeal paralysis may accompany lesions other than the degenerative process in the nuclei of medulla, would excuse a brief consideration of the classification given by Collins in "Twentieth Century Practice."

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee: Drs. Edwin Rosenthal, H. M. McClanahan and Samuel W. Kelley.

This author presents these paralyses with reference to their etiology under eight heads. With your permission I will give them seriatim in comparison with the clinical findings of the case before us.

COLLINS' CLASSIFICATION.

1. Progressive labio-glosso-laryngeal paralysis.
2. Primary vascular lesions; (*a*) acute inflammatory; (*b*) bulbar hemorrhage; (*c*) thrombosis and embolism.
3. Bulbar neuritis (associated neuritis of bulbar nerves).
4. Infantile bulbar paralysis; (*a*) familiary; (*b*) hereditary.
5. Secondary degenerative lesions of the bulb; (*a*) in amyotrophic lateral sclerosis; (*b*) in syringomyelia; (*c*) in tabes and multiple sclerosis.
6. Pseudobulbar paralysis (cerebral).
7. Tumors of medulla oblongata, including gummata.
8. Bulbar paralysis without anatomic foundation (asthenic bulbar paralysis).

From his second class, due to vascular disturbances, this case may be excluded by its gradual onset and absence of acute symptoms, as fever, disturbance of pulse rate, vomiting, etc.

For the same reason (gradual onset) we may rule out class three, viz., associated neuritis of bulbar nerves, which condition not only causes a rapid development of symptoms, but is rarely reported as furnishing all the symptom-complex of true bulbar paralysis.

The fourth class (familiary or hereditary type) we may possibly exclude, for want of corroborative history, her brothers and sisters being free from any suggestion of similar trouble.

There is no evidence of any involvement of the cord, such as spasticity, increased muscular irritability or atrophy.

Lack of sensory disturbances, as analgesia, thermic anesthesia and also lack of muscular atrophies may exclude syringomyelia.

The persistence of the patellar reflex, absence of crises and the Argyll-Robertson pupil may allow us to dismiss tabes from consideration, and, although we have a slight nystagmus, the intention tremor, scanning speech, rigidity and exaggerated knee-jerks of multiple sclerosis are wanting. If, as it has been claimed, an isolated area of a developing multiple sclerosis have its seat in the medulla and produces the symptoms seen in this patient, may we not claim that it is time (seven months) for the symptoms of other scleroses areas to manifest themselves?

In pseudobulbar (cerebral) paralysis we should expect a sudden onset with possible subsequent improvement until there is a second attack, possibly hemiplegia; the atrophy should be that of inanition and the muscles should not show the reaction of degeneration. Especially is atrophy of the tongue wanting. Nor is pseudobulbar paralysis long free from other evidences of cerebral involvement, as mental impairment and emotional disturbances.

From tumor of the medulla it is possible that enough time has not yet elapsed for the development of sufficient symptoms to make positive differentiation. Indeed, we have already involvement of the upper facial muscles and slight involvement of the ocular muscles. However, the negative condition of the fundus, absence of sensory disturbances, cephalagia, etc., might lead us to exclude a tumor of any considerable size. The entire absence of any other signs of syphilis renders the diagnosis of gummata improbable.

Asthenic bulbar paralysis, without anatomic foundation, is not recorded as showing true muscular atrophy with the reaction of degeneration. Nor is its course steadily progressive; on the contrary, almost complete cessation of symptoms follows intervals of rest.

The extensive involvement of the facial nerve seen in this case, though not of itself a part of the symptom-complex of true bulbar paralysis, still occurs with sufficient frequency not to jeopardize our diagnosis, providing the pathognomonic symptoms be present. As to the ear involvement, the history of partial deafness for the past three years would indicate merely a coincidental condition.

It seems to the writer that from the symptoms present, the course of the disease and the onset, he is justified in classing this case as degenerative bulbar paralysis. The extreme rareness of this affection in a female child lends exceptional interest to this case.

AUTOPSY REPORT BY DR. P. BASSOE.

April 8, 1902.—The autopsy was held about eighteen hours after death and was limited to the removal of the brain and spinal cord.

General.—The body was poorly nourished. Rigor mortis slight. Lividity posteriorly. No external marks except an opening to the left of the umbilicus through which embalming fluid had been injected. No injection had been made into the vessels. The scalp and skull presented no changes. There were no abnormalities of the meninges. The brain and cord showed no changes externally and were immediately placed in a 10 per cent. solution of formalin in water and carefully suspended. An opening was made into the abdominal cavity from behind. The spleen was removed and found of normal size. The kidneys also of normal size, capsules not adherent, section dark red, cortical markings distinct.

Brain.—The brain and cord were sectioned later and showed no gross changes. After preliminary formalin hardening the medulla was placed in Müller's fluid. Serial sections will be made later. Pieces of cortex and cord were taken at the autopsy, placed in 96 per cent. alcohol, cut without embedding and stained by Nissl's method. In most of the ganglion cells of the frontal lobe a normal condition of the nucleus, nucleolus and Nissl bodies is seen. In a few cells the Nissl bodies between the nucleus and base of the cell have been broken up into fine particles, less deeply stained than the normal Nissl bodies. A number of vessels cut longitudinally are filled with red corpuscles. There are no perivascular infiltrations.

Motor Area.—The cells show distinctly outlined generally, centrally situated nuclei with nucleoli. In several cells there is a rim of unstained protoplasm around the nucleus, the stainable substance being arranged along the periphery of the cells as densely aggregated small granules. The vessels are normal.

Cervical Cord.—In specimens stained by the Marchi method degenerated fibers were scattered in every portion. They seemed more numerous in the direct pyramidal and cerebellar tracts than elsewhere. However, they were not numerous enough to leave marked gaps in Weigert-Pal preparations. The gray matter was normal. Marchi preparations from the lower portion of the medulla showed scattered degenerated fibers in the lateral columns. The posterior columns and pyramids were practically uninvolved, and show a normal number of fibers in Weigert-Pal preparations.

As stated before, the remainder of the medulla has not been examined yet.

DISCUSSION.

DR. J. M. DODSON, Chicago—I take it that the question in this case is one of central or peripheral lesion. The history of an antecedent diphtheria, of course, suggests itself in this connection, although the long interval that had elapsed from the last attack of the disease and the onset of symptoms seems almost to negative that possibility. Yet I think it does not do so entirely. I shall look with interest for the publication of the report of the complete postmortem findings.

DR. COTTON—Seeing this case for the first time in clinic, I made a snap diagnosis of bulbar paralysis as one of the possibilities, because of the symptoms presented. Meeting the mother afterward, I was surprised at her intelligence regarding the symptoms of paralysis, and I then found she had

been to other clinics. She had been encouraged to believe in the recovery of the child from the fact that a diagnosis of postdiphtheritic paralysis had been made in a neurologic clinic. The length of time intervening, however, between the attack of diphtheria and the occurrence of the paralysis was greater than I had ever seen in such a case. The fact that the disease had progressed three months before coming under my observation led me to exclude postdiphtheritic paralysis as we understand it by that name. The suggestion of intoxication from infection as affecting the function of nerves is, of course, a wide field for speculation, and the cases of pseudoparalysis without anatomic foundation remain yet unexplained. The autopsy thus far in my case seems to confirm the diagnosis; however, it would be just as interesting to us all if the autopsy were negative. That all the symptoms of bulbar paralysis should be present without any anatomic changes in the bulb or other nerve structures would certainly be remarkable. Such cases are recorded, however, as asthenic bulbar paralysis, according to Oppenheim and others, without anatomic lesion yet discoverable.

Special Article.

THE TYPHOID EPIDEMIC AT ITHACA.

(By our Special Commissioner.)

III.

THE IMMEDIATE CAUSE OF THE EPIDEMIC.

In casting about for some special cause for the epidemic, public attention naturally became focused on the fact that a band of Italian workmen had been employed in the work of preparing a dam site and reservoir projected by the Ithaca Water Company, the private corporation controlling the Six Mile Creek and Buttermilk Creek supplies. Considerable friction had been generated between the water company and the townspeople over the construction of the proposed dam, and public opinion seized, with a not unnatural avidity, on the presence of the Italian laborers as affording a satisfactory explanation for the outbreak. About 100 of these workmen were employed in the gorge of the stream at a point nearly one mile above the intake, up to about the middle of November, 1902, and during the months of November and December men and teams belonging to the town were also engaged in work on the dam and its surroundings. One gang of Italians was controlled by the contractors and one, working below the dam, by the water company itself. According to the statements of the officials of the water company, the Italians did not work in the gorge after November 14, and, although they remained at work in the vicinity for some time longer, all but twelve were discharged on December 12, and all were discharged on December 19. There is evidence that both the contractors and the officials of the water company were alive to the responsibility entailed by the presence of these workmen at this critical point, and that measures were taken to prevent the fouling of the stream. It is said that lime was used in large quantities for the destruction of and the disinfection of the excreta. At the same time, there is abundant evidence for believing that, however careful the supervision of the Italians may have been, contamination of the stream and its banks was not altogether prevented. Many observers testify to having witnessed in the neighborhood of the camps a state of things which was far from reassuring, and which, in the light of subsequent events, throws much suspicion on the presence of these men. No information can be obtained, however, regarding the occurrence of any case of illness among these workmen, and there is no record indicating that other than good health was maintained among the whole crew during the period of their work.

It is certainly a seductive hypothesis that the presence of these workmen is connected with the epidemic that followed a few months later, but after a careful examination of the site of the dam and the surroundings of the camps of the Italians, and after a consideration of the dates at which the workmen were employed in the gorge and the dates at which the early cases of fever developed, the writer is unable to find any convincing evidence for this view. The meteorological record shows that during the months of November and December, 1902, heavy rains and periods of thaw occurred several times, so that if infectious material in large quantities had been deposited by any of the Italians on the banks of the stream, such material would have been most likely to find its way into the water at a date considerably earlier than that which marks the beginning of the present epidemic. Furthermore, while it is conceivable that a typhoid convalescent with an infectious urine discharge, might have been present among the Italians during the period of their stay in Ithaca, it does not seem likely that either the character or the quantity of the infectious material discharged by such a convalescent would have been sufficient to produce a severe outbreak after the lapse of several weeks. The more plausible supposition that a mild or "walking" case of typhoid fever existed among the workmen, and that the washing into the stream of the accumulated bowel discharges of such a patient caused the present outbreak seems to be rendered somewhat problematical by the utter absence of evidence that any such case existed and by the facts of the meteorological record. One is undoubtedly tempted to suppose that the presence of these workmen in the gorge is connected in one way or another with the outbreak, but, in view of all the facts, such a hypothesis must be accepted with some hesitation.

It seems, indeed, quite as reasonable to assume that a case of typhoid fever, possibly in a mild and unrecognized form, existed at some point on the Six Mile Creek watershed, and that the discharges from such a case either passed directly into the creek or were washed down from some one of the scores of privies that afford opportunity for such a mode of contamination. The sanitary history of Ithaca, as has been already pointed out, shows that infection of the water has probably occurred in the past on more than one occasion. The outbreak of fever in 1902, it should be remembered, was a spring epidemic only less severe than that of the present year.

In favor of the view that a case of typhoid fever existed somewhere on the watershed during the month of January, 1903, might be urged the fact that the extent and duration of the infection suggest the presence in the water of the stream of a very large amount of infectious material and also of a continuance of the infectivity of the water over many days. It should be kept in mind that the stream in question is small, that its current is swift, and that there is practically no storage, so that the conditions are radically different from those obtaining in the case of a polluted lake or reservoir. It is quite possible, as has been suggested, that material from an infected privy may have been spread as manure on the surface of a field bordering on the stream itself or on one of its rapidly flowing tributaries.

Certain analogies with the famous Plymouth, Pa., epidemic of 1885 at first inclined several observers to seek for some connection between the "January thaws" and the outbreak of typhoid fever in Ithaca, but such a connection, if it exists, is not obvious. As is well known, the period of incubation in typhoid is somewhat uncertain, but the best authorities agree that a period of at least eight to fourteen days generally precedes the manifestation of definite symptoms, and in many cases the incubation period is as long as twenty-one days, or even longer. It will be seen by reference to Table 2 that the maximum number of cases that occurred among the students developed during the three-day period, February 4-6, which would place the period of infection about January 21-23, if it were assumed that fourteen days had elapsed since infection. It will be noticed, however, that many cases of typhoid fever appeared among the students considerably earlier than this, and, even allowing for an incubation period as brief as eight days, some individuals must have been infected much earlier than January 21. This inference is confirmed by the undoubted fact that many cases of typhoid fever appeared in Ithaca during the week January 19-26. On January 26 one of the local papers *(Ithaca Daily News)* contained the statement that 73 cases of fever existed in the town, and this statement was one of the first published indications of the existence of an epidemic. During the following week many more cases were reported, and on February 2 237 cases were said to exist in Ithaca.

All these facts (see especially Table 2*) indicate that the active agency in the infection was operative during at least several weeks, possibly extending from the first of January to the middle of February. There is no conclusive evidence of a sudden outburst of infection confined to a few days and terminating more or less abruptly. On the contrary, the facts rather point to a specific contamination that persisted for several weeks. The meteorological table shows that there was an extended thaw lasting from the first of January to the fourth; a slighter one about the middle of the month (Jan. 16-17), and the most marked of all January 27-30. It is certainly possible that the thaw early in January may have had some connection with the first cases to be reported, but if that were true one would expect that the onset of the epidemic would have been marked by a more explosive character than was actually the case. As a matter of fact, the beginnings of the outbreak were apparently quite gradual. It may be noted, for example, that the first patient was admitted to the University Infirmary on January 23, a date some days after cases of typhoid fever had made their appearance in the town, and it was not until about February 1 that the number of cases among the students began to assume highly alarming proportions. The most extended thaw of all, January 27-30, does not seem to have had any noticeable effect on the number of cases, unless one assumes that the cases developing between February 4-6 could be traced to infection at the time of this thaw. This, however, seems hardly likely, since a period of incubation so much shorter than the average would hardly have occurred in the maximum number of cases, and it would naturally be anticipated that the effect of this thaw would manifest itself especially about February 11-14, a time when the epidemic was plainly relaxing its hold (Table 2). The rather insidious beginnings of the outbreak, followed by a slow rise to a period of maximum infection and its final tardy and reluctant dying out, are not facts that betray the existence of any definite relation between any particular January thaw and the infection, although it seems only fair to suppose that such thaws may have served, from time to time, to accentuate the pollution.

MANAGEMENT OF THE EPIDEMIC.

Both town and university authorities have been subjected to unsparing criticism in various quarters for the overcrowding of the city hospital and the University Infirmary, and for the general management of the epidemic conditions. With respect to the overcrowding, such criticism has, perhaps, not been wholly just. There is no doubt that both hospital and infirmary have been greatly overtaxed almost from the beginning of the epidemic, but it is difficult to see how this could have been altogether avoided. The proportion of cases to the population has been very high, and both Ithaca and the university are to be congratulated that the facilities for caring for the patients were as ample as was the case. Few small towns and few universities are adequately provided with hospital accommodations for such an extraordinary emergency. The authorities of New York or Chicago would assuredly find themselves beset with many difficulties if they were suddenly called on to face the necessity of caring for 100,000 typhoid patients, and yet the proportion of cases to population in Ithaca was probably at least as large as this. The University Infirmary and its management, in particular, have received a great deal of sharp criticism, and it seems to be nowhere questioned that during the height of the epi-

* See p. 783, issue of March 21.

demic the conditions in that institution were more like those of war times than of ideal hospital practice. Unavoidable overcrowding was, of course, present, and one is told that there was much of the confusion that has sometimes accompanied great military emergencies. High praise is due the physicians of Ithaca, who, under such adverse circumstances, must have been severely overtaxed. With less than 30 physicians in the town and with sometimes over 400 typhoid patients added to their usual work, the conditions of the work can be understood. The highest appreciation of the efforts of the physicians was everywhere expressed. Whatever may have been their opinion as to the nature of the epidemic in its beginnings, there is no reason to believe that individual disinfection and prophylaxis were neglected, and, as already said, many of them showed themselves fully alive to the situation from the very first.

A particularly fortunate element was introduced into the situation by the arrival of Dr. George A. Soper of New York, representing the New York State Board of Health. The situation was one eminently demanding energy and great judgment. Dr. Soper won from the outset the confidence of all factions and immediately infused a spirit of system and hopefulness into the whole city. A particularly active campaign has been waged under his direction against the possibilities of secondary infection, and if the reforms suggested and initiated by him are carried into effect, Ithaca should be the cleanest and most ideally hygienic town in the state of New York. Only the highest praise can be awarded to the character of the methods, both physical and tactical, employed in this work. It is certainly one of the hopeful signs of the times that a man of practical experience and energy, combined with scientific knowledge, should be placed in a position of authority.

SECONDARY INFECTION.

The presence in Ithaca of the enormous number of typhoid bacilli generated in the bodies of 700-800 patients caused much concern among those conversant with the methods of spread of typhoid fever. The well-known dangers of secondary infection, a term generally applied to direct transfer of the specific bacilli from one individual to another through carelessness in disinfecting the discharges, were undoubtedly very great. The peril of further spread of the disease by this means was early appreciated, and a warfare against filth of every description was waged, and the discharges of typhoid patients were rigorously taken care of. Owing to energetic and efficient methods, the opportunities for secondary infection have been greatly diminished, and the aftermath of such cases will probably be much smaller in Ithaca than in most typhoid epidemics.

As to the part that has been played by secondary infection in originating cases of typhoid during the course of the epidemic, opinion is at variance. The fact that many cases developed among the members of one household or among the students in the same fraternity house or boarding house, together with the fact that in some cases a definite interval elapsed between the infection of different individuals has seemed to some to indicate that secondary infection has been of rather frequent occurrence. On the other hand, it is pointed out that the large number of individuals residing in a single boarding house lessens, somewhat, the value of the evidence derived from the appearance of many cases at the same house number, and it is also noted that the interval elapsing between the successive cases has been almost invariably less than the average period of incubation for typhoid fever. There can be no question that in this, as in all extensive outbreaks of typhoid fever, secondary infection has played a part, but there does not seem any reason for assigning it other than a strictly subordinate rôle. Cases of this character, however, would undoubtedly have been more numerous in the later stages of the epidemic but for the methods of prevention already alluded to.

THE OUTLOOK FOR A PURE WATER SUPPLY IN ITHACA.

Public opinion in Ithaca has become thoroughly aroused, and town and university authorities have been working with notable zeal to obtain a pure water supply. The revulsion of feeling over the use of surface water has led to an enthusiastic attempt to obtain a supply from artesian wells. A citizens' committee has taken up this matter with great vigor, and under their direction wells are now being drilled at different points in the valley, with the aim of securing an exceptionally pure and abundant supply. It is said, however, that competent engineers who have examined the locality are unable to secure any evidence that a supply satisfactory in quantity and quality can be derived from this source. Experiments are now in progress designed to determine this point, and, since there exists an overwhelming sentiment among the inhabitants of Ithaca in favor of deep well water and against surface water, the question is likely to be probed to the bottom.

At the same time that wells are being drilled in the valley a plan for filtering the water of Six Mile Creek is well under way. The water company has secured as consultant Mr. Allen Hazen, who has had large experience in matters of water purification and who is well known as the designer of the filtration plant now in successful operation at Albany, N. Y. Any measure carried out by his advice and under his supervision may be received with entire confidence by the people of Ithaca as a satisfactory solution of the problem. A slow sand filter, constructed from Mr. Hazen's designs, will unquestionably assure the city a supply of pure and wholesome water. It is expected that a thorough inspection of the watershed will go hand in hand with the preparations for filtration and that many improvements will be carried out along the banks of this stream. When this is effected and the filter plant is in operation under competent management, typhoid fever should practically disappear, and "Ithaca fever" be relegated to well-deserved oblivion.

The university authorities have determined to depend no longer on the supply of raw water from Fall Creek, and are installing a small mechanical filter which will be completed in a few weeks, and which is expected to ward off the possibilities of danger from this source. During the epidemic the university has supplied artesian well water for the drinking tanks in the campus buildings, and to its prompt action in this respect a considerable degree of immunity among the students during the later stages of the epidemic must be attributed.

Among the many persons in Ithaca to whom I am under obligations for friendly courtesies, I wish to express my especial indebtedness to Prof. V. A. Moore of Cornell University, who has generously placed at my disposal much information concerning the epidemic, and also to Dr. George A. Soper, who has kindly aided me in the course of my inquiries in many ways.

POSTSCRIPT.

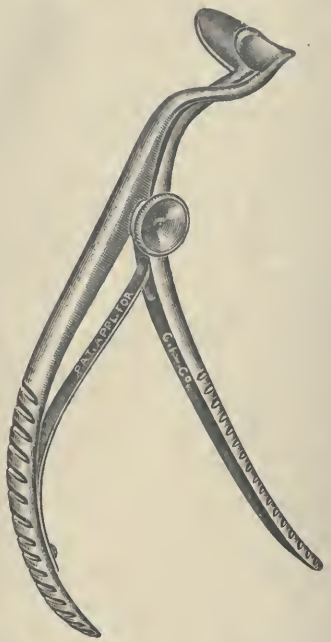
The epidemic is now, March 30, to all appearances, at an end. Only fourteen new cases have been reported since March 11, and during the last week there have been only four. The revised and corrected tabulation of cases on the best information obtainable is as follows:

	Students.	Citizens.	Total.
Cases in Ithaca	124	660	784
Cases outside of Ithaca	106	22	128
Total	230	682	912

The corrected list of deaths to the present date is as follows:

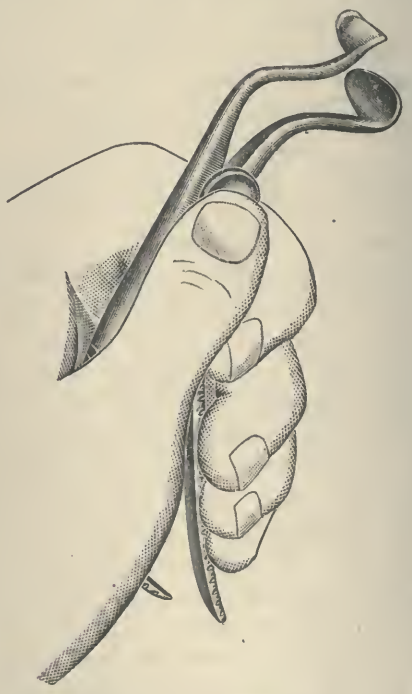
January 23 to January 29	1
January 30 to February 5	4
February 6 to February 12	7
February 12 to February 19	12
February 20 to February 26	11
February 26 to March 5	10
March 6 to March 12	5
March 13 to March 19	5
March 20 to March 26	2
March 28	1
Total	58

Twenty-six of this number were students in Cornell University.



New Instruments.

A NEW NASAL SPECULUM.



O. B. MONOSMITH, M.D.
LORAIN, OHIO.

Realizing that the bivalve speculum, opening transversely, did not meet all of the requirements of a nasal speculum, I was led to devise one for my own use that would overcome these difficulties. That I have succeeded, at least to my own satisfaction, is the excuse for presenting it to the profession. Its evolution extended over a period of about three years, during which time I made many modifications. The model, a cut of which I present, I have used about a year, and, in the majority of nares, it meets all of the requirements of an ideal speculum, both diagnostic and operative. It has merits that will appeal to the specialist as well as the general practitioner.

The instrument is to be held in the left hand of the operator for both nares, with the ball of the thumb on the screw head, thus giving a firm hold of the instrument without necessarily forcing the blades apart. By holding the instrument in this manner the blades open vertically. The advantage of this is that it raises the tip of the nose, giving a more advantageous angle of illumination and a better view of the nasal cavities. Another advantage is that the blades do not touch the mucous membrane. It will be seen that the upper blade is much shorter, and is placed somewhat back of the lower blade. It is also hooked slightly upward. This is, perhaps, the most important feature of the instrument. Being shorter and placed back of the lower blade, it conforms perfectly to the

anatomy of the nose, allowing both blades to enter the nose without leaving anything outside that is superfluous. The blades being attached to the shanks at right angles, prevent their being forced inward against the mucous membrane, and the upward curve of the upper blade prevents the speculum

slipping out at inopportune times, especially while operating. It may be noted, in passing, that with any bivalve speculum it is occasionally necessary to clip out the hair that is sometimes found in the anterior nares, in order to get a perfect view of the nasal cavities. A patent has been secured on the instrument, with the sole purpose of giving the control of the

manufacture to one instrument house that can be depended on to make it right, otherwise the merits of the instrument would be spoiled. As to the wisdom of this, I refer to an article in The Journal of the American Medical Association, vol. xxxvii, p. 1336, by Dr. Frank Allport, in which he writes: "As it is now, the moment he publishes an instrument all manufacturers have a right to make it, and, before long, the instrument on the market bearing the inventor's name may be so far removed from his original idea as to make him ashamed that he ever gave it to the profession."

THE THIERY CLAMP.

A SUBSTITUTE FOR EXTERNAL SUTURES.

ANDREW B. GLONINGER, M.D.
Surgeon to Good Samaritan Hospital.
LEBANON, PA.

I would like to give your readers the benefit of an idea that I picked up in Paris last summer at Professor Thiery's clinic. It is a little clamp, invented by Thiery to take the

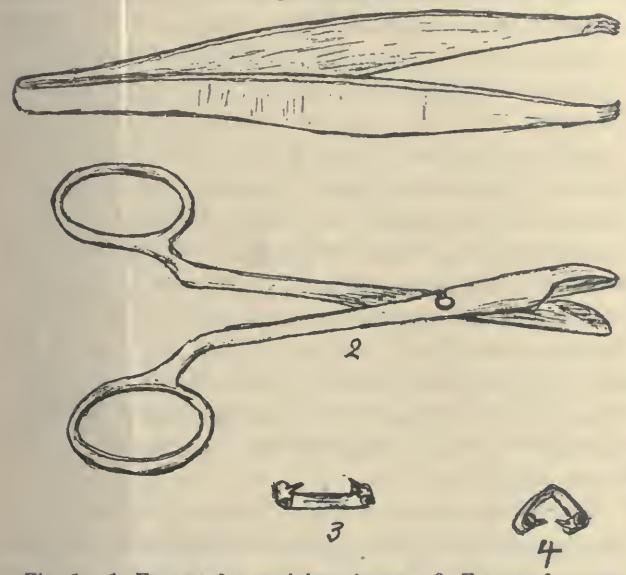


Fig. 1.—1. Forceps for applying clamps. 2. Forceps for removing clamps. 3. Clamp before application. 4. Position of clamp when in use.

place of superficial sutures, which saves time in closing incisions after operations and prevents troublesome stitch abscesses.

The clamp itself is a narrow strip of soft non-corrosive metal 1¼ cm. in length, the ends curled and armed with little spurs.

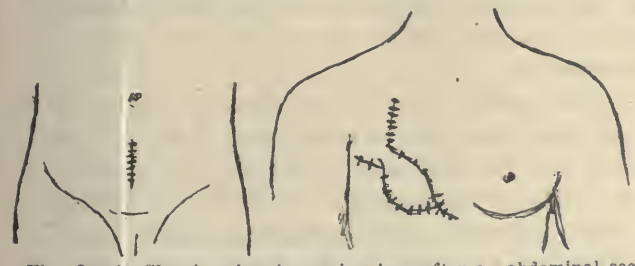

Fig. 2.—1. Showing the clamps in place after an abdominal section. 2. Showing the clamps holding a flap in place, reinforced by silkworm-gut suture at points where tension is greatest.

The two skin surfaces to be united are held in apposition between thumb and forefinger and the clamp, held in the grasp of a heavy claw-tipped dressing forceps, is pressed lightly against the adapted edges and pinched on with slight pressure. The little instrument bends easily, and the points enter the skin, holding the edges firmly together. They should be removed on the fourth day. For this an ordinary small hemostatic forceps will do, but the forceps specially designed for the purpose has a prominence on one jaw and a depression in the other; the grooved jaw is slipped under the clamp, and when the other is closed on it it bends back readily into its original shape with very little annoyance to the patient, leaving only a small cicatrix along the line of incision.

The outfit, including the two pairs of forceps and 500 clamps, cost me 20 francs in Paris. They can be used in all sorts of incised wounds where the tension is not great.

In abdominal operations they are the ideal suture. In fifteen sections I had complete union in four days in all but one, in which I had used some deep sutures on account of an unusually thick layer of fat. Following an amputation of the breast, I use two or three silkworm-gut sutures where there is tension and finish with clamps. I have had good results in closing incisions after phlebotomy for transfusion or for the ligation of varicose veins, and I tried them in two cases of amputation of the leg, but the grasp did not seem to be strong enough to hold the flap, and the result was not very satisfactory. They are specially well adapted for incisions of face, scalp and neck on account of the small cicatrix.

The misconstruction of the Code of Ethics which enjoins physicians against the methods of advertising like the quacks, i. e., by offering to give public advice to the poor gratis and by private cards or public handbills proclaiming one's skill to cure special diseases, has deterred capable physicians from imparting the kind of information they ought to impart on all proper occasions to the public. Up to date the public has obtained most of its knowledge indirectly from published accounts of epidemics, etc., and what health boards are doing and from occasional newspaper extracts from medical society proceedings selected on the judgment of non-professional and of inexpert newspaper reporters and from the alarming, overdrawn and often perverted statements made in quack advertisements. Often the first and only knowledge of what the medical profession is doing gets to the public through the last-named mercenary channels, who often pay tribute to the great work of the medical profession by indirect reference to the merits of its dead masters and by naming their quack establishments and more or less fake remedies after our great names. For we know, though the public does not, how many of the patent medicine men of our time have been simply drug store clerks or bottle washers or porters sometimes in physicians' offices, evoluted and transformed into patent medicine proprietors and kings of gullibility and Napoleons of fake finance founded on humbug—folly in matters medical and fake healing with the people, because we who have the light to shed give it not, but leave the popular medical world in darkness.—"Alienist and Neurologist."

The proportion of accidents and disease is brought out by an analysis of a recent census report made by the "Insurance Press," from which we learn that deaths due to accidents and injuries were highest among those whose mothers were born in Italy (119.5 per 100,000 of white population); lowest among those whose mothers were born in the United States (62.7). The death rate due to accidents and injuries is highest among persons 45 years of age and over. The average age at death from accidents is about 33.5. The proportions of death from accidents and injuries were greatest in the Cordilleran regions, the Pacific coast region and the Western plains; they are least in the North Atlantic coast region, the Middle Atlantic coast region and the Northeastern hills and plateaus. The warmer months show a larger proportion of fatal accidents than the cooler months. A person is more liable to meet death by accidental injuries than by any other single cause, except tuberculosis, pneumonia or heart disease. One is twice as liable to die from accident as from old age Typhoid fever, cancer, apoplexy, inflammation of the brain and meningitis, paralysis, diphtheria, diseases of the stomach, liver and brain, all these are slight menaces to life compared with the accident hazard If, as seems not unreasonable, a person is liable to die of any disabling accident that happens to him, what is to be said concerning the 11,000,000 accidents that happen every year. It seems to be true that a person is 100 times more liable to "catch" an accident than a fatal case of tuberculosis or pneumonia, and about 1,000 times more liable to "catch" an accident that a fatal case of liver disease.—"Amer. Medicine."

SATURDAY, APRIL 4, 1903.

INVESTMENTS FOR PHYSICIANS.

It is a matter of common remark among bankers and business men that physicians, more than members of any other profession, unless it be the clergy, are prone to make unwise investments of their savings. Medical men, it is true, are among the most far-seeing of individuals as far as the judgment of the character of their fellow-man is concerned; in general, they are noted for the common sense they display in the ordinary dealings of life. Too often, however, the sense of proportion seems to abandon them when it comes to matters relating to their financial welfare. The reason is largely, in our opinion, to be found in the widespread misunderstanding which exists among members of the profession regarding the fundamental principles underlying investments. How often in moving among medical men do we hear comments on "investments" in mining stocks, in oil wells, in rubber plantations or in industrial companies of various types. It is no unusual occurrence to be recommended by a friendly-disposed fellow practitioner to remove our accumulated little surplus from the savings bank and to buy ignis fatuus oil stock that is paying 12 per cent. dividends, or to sell our Chicago & Northwestern railway bonds and purchase Guatemala rubber and coffee stock at 50 cents per share because it is announced that the price will be advanced to 75 cents next month. The promoters of these will-o'-the-wisp concerns are only too well aware of the ease with which large numbers of medical men can be induced to venture in them; that they make good use of medical directories the daily mail of every medical man in the country attests.

It is doubtless to the credit of the majority of medical men that they are ignorant of the details connected with the selling of stock and bonds, that they know nothing of "puts" and "calls," and that the "short interest" and "stop-loss orders" are terms which are mysteries to them. A man to be well versed in all the minutiæ of Wall street or La Salle street should give his whole time to the occupation and he will be fortunate then if he learns how to trade with profit. The physician who is to be a success in his profession and an honor to it, must give as much time and thought to that profession as old John Graham advised his son to give to pork. If he attempts to speculate in stocks and to practice medicine at the same time he may not be the most closely-shorn of the "lambs" in the street, but he will almost certainly deteriorate as a physician in the homes of his patients.

It is important to distinguish between "investment of savings" and "investment for large profits." In the latter instance over-ambition is likely to lead to indulgence in semi-speculative investments or to the yielding to pure speculation in so-called securities which are really nothing more nor less than gambling counters.

If Simeon Teluya of the Province of Moncostenango in Guatemala were to write to a thousand physicians and ask each one of them to lend him a hundred dollars, it is very improbable that he would receive favorable answers to his request; at any rate, before loaning the $100 to a man unknown to him and living so far away, inquiry would first be made as to the reliability of the man and the security of such a loan. But let Simeon Teluya stake out a few acres of Gautemala highlands or marsh, and, with the help of an enterprising American promoter who has a couple of hundred dollars with which to begin a new scheme, organize a company with $3,000,000 capital, advertise broadcast that rubber trees which have been planted are rapidly developing and that meanwhile the yield of coffee will speedily make dividends possible, send printed prospectuses to physicians stating that this month is the last opportunity to secure "treasury stock," and that next month the price of each share will be doubled, and it is surprising how many "conservative" men, without investigating in the slightest way Simeon or his plantation, will mail their checks for the stock.

Now there can be no doubt that some rubber plantations are exceedingly profitable and that there have been mines and oil wells which have turned small investments into great fortunes. Many of the ventures exploited represent opportunities of actual value; more of them have an honest purpose behind them, but ultimately prove unprofitable, but those who have watched the course of such concerns most closely tell us that a "large proportion of such offerings afford little or no return to the public who risk their money in the scheme."

Safety of the principal is of much greater importance than large dividends or a high rate of interest. Rather than run any large risk it is better to be satisfied with the small rate of income which pertains to the so-called "widows' and orphans' investments," such as are provided by savings banks, government and conservative municipal bonds, endowment insurance in first-class companies, or first mortgages on real estate worth twice the face of the mortgage, and which is producing income considerably in excess of the interest on the mortgage and is owned by some one who has other property than that on which the mortgage is held.

Certain bonds and stocks can be purchased with safety; others are risky. One of the most important principles which should be grasped is this: It is never wise to invest in securities of which one can not have full

knowledge. This is why it is better to invest in the securities of local companies which serve essential local needs, like light, water and transportation; for the physician if he invests in his own town or city, ought to be better able to make sure whether or not the companies whose bonds he purchases are honestly and economically managed, than if he buys the bonds of companies operating in distant cities. He should study the company's reports, be sure that he understands what every item means, keep in close touch with the officers thereof and know as much as possible of the nature of the business. The advantages of seeking all one's business profits within the range of his own immediate and more or less expert observations can scarcely be over-estimated. The securities of companies, and especially of industrial concerns, which avoid publicity, and of which no adequate account of resources and liabilities, of relation of fixed charges to net earnings, and of relation of dividend distributions to surplus earnings can be obtained should be shunned as assiduously as the substitution of morphin for quinin.

A second fundamental verity with regard to investments is to be found in the fact that "the return on a security always indicates the measure of the risk." An examination of the yield of different classes of bonds will show that government bonds return about 2 per cent.; high-class municipal bonds about 3 per cent., and railway bonds of the best class from 3.25 to 4.5 per cent. If on inquiry a bond or stock be found to be selling at a price which permits of a net yield of over 5 per cent. it is either because there is a limited market for the security or the investing public doubts the stability of the return. Occasionally there is to be picked up a really safe security which yields more than 5 per cent. net return, but this is rare, and there is always some special reason to account for its cheapness.

A third law of investments is this: A large proportion of new business undertakings fail; it is therefore rarely wise to put money into any new enterprise. Such a disposition of money must be looked on as speculation rather than as an investment. It is much safer to limit one's purchases to the bonds, for example, of railways and corporations, which, through a series of years (including a period of hard times), have demonstrated their ability to pay all their fixed charges with 60 per cent. or less of their net earnings. If the stocks of first-class railroads are ever purchased (and they are, of course, always much less safe than the bonds of the same roads) the investor should first make sure of the margin of safety of surplus earnings over dividends; if, after all fixed charges have been paid, more than 60 per cent. of the surplus earnings have been distributed as dividends at any time during the preceding five or ten years, the stock should not be bought as a prime investment.

Fourthly, a physician should never intrust money for investment to any person or company who offers to place great skill in reading the markets at the disposal of the investor in exchange for a practical part of the large profits promised. Discretionary pools, trading syndicates and all such "get-rich-quick" concerns are to be avoided as one would the arch enemy. Promises of 10 per cent. return or more monthly are to be regarded as opportunities for falling into a snare, and the snare is very often a tangle which ends in disgrace. If discretionary pools had that clairvoyant knowledge of the immediate movements of the market which would permit them to make the money for their clients that they claim, they would be in the market entirely on their own account, and not be wasting time working on small commissions for other people. Fortunately the postal authorities are ridding the country of the worst of these pests as fast as their attention is called to them.

In conclusion, if medical men would learn to follow the advice of a sage counselor and "lend no money as a favor to anyone unless you are willing and able, if need be, to give the money outright; to have no business dealings with your relatives in which business and sentiment are mixed up; sign no notes and assume no financial responsibilities for other people . . . and never put a large part of your savings into any one investment," there would be many fewer heart burnings in old age and many happier physicians' families than there are to-day.

THE NOMENCLATURE OF CYTOLYSIS AND BACTERIOLYSIS.

The terms intermediary body, complement, etc., have appeared repeatedly in these columns in discussing some of the phenomena of the reactions of immunity. Although the functions of these bodies, which are made clear by certain observed phenomena rather than through the isolation of tangible substances, are now fairly well understood by scientific workers and general readers, there is among the contributors of various countries a reprehensible lack of unanimity in the terminology employed. This must needs lead to a degree of confusion among medical men in general in their attempts to grasp a problem which, primarily, is not simple.

In view of this, a brief consideration of the nomenclature of immunity seems appropriate. It is now generally understood that so-called cytolytic and bacteriolytic serum contains two substances, one thermostabile, and one thermolabile, which is destroyed by about 56 C. for thirty minutes. The thermostabile substance combines with the cell (animal or bacterial) for which it is specific, gaining entrance through the theoretical cell "receptors," of which every cell has a great variety. After this union has taken place, something happens by means of which the thermolabile substance in some way can enter or be joined to the cell and produce its solution. Without the first step the second can not occur, and they must occur in this order. We have, then, to do with three different "bodies" in the process of cytolysis: the cell with its receptor, the thermostabile body (intermediary body or amboceptor), and the thermolabile body (complement).

The amboceptor or intermediary body has a certain amount of complexity in that it has two different affinities, one for the cell and one for the complement. It has been supposed that these affinities reside in definite molecular groups of the amboceptor, and, in accordance with their function, they are called binding groups (haptophorous groups or simply haptophores). The group with affinity for the cell is the cytophilous, for the complement the complementophilous group of haptophores. Now the amboceptor, under certain circumstances, may undergo a kind of degeneration, in that it may lose its binding group on the one hand for the cell, or on the other for the complement. The degenerated body is an *amboceptoid* (Wechsberg).

The complement also is not simple in its constitution. It is the active or digesting substance of an immune serum, the amboceptor being an intermediary body. It has been shown that the complement degenerates spontaneously with ease, losing its power to cause lysis, but retaining the power to combine with the complementophilous group of the amboceptor. In this way the amboceptors are used up, and active complements which may happen to be present can not come into play. The degenerated complement is called *complementoid.* Although it is inactive in this form, when injected into animals it is able to give rise to the formation of *anticomplement,* because it retains its haptophorous group. That part of the complement which digests the cell, and is so sensitive, is the toxophorous group, or the toxophore.

Various sera are designated thus: bacteriolysin, hemolysin, leucolysin, spermolysin, endotheliolysin, and so on through the whole list of available cells. The amboceptors are the specific elements in these sera, and while some are present normally they are produced to an enormous degree in immunization; complements seem to be less specific and are not increased in immunization.

The relationship of animal species has made necessary another group of names. If the serum or fluids of an animal will dissolve its own cells the phenomenon is called autolysis; if a member of a species can naturally, or through immunization, cause lysis of cells of another member of the same species, isolysis is spoken of; and heterolysis, if the serum dissolves the cells of an animal belonging to a different species. The respective amboceptors are autolysin, isolysin, and heterolysin.

Agglutinins, precipitins and coagulins are additional bodies which are produced by injecting animals with different substances. They are simple compared with the amboceptors, and are called unicceptors, having a haptophorous group and supposedly a toxophorous (agglutinophorous); thus they have a structure similar to that of complement and also of toxin, which latter can not be discussed now. Certain bacteria produce in bouillon cultures substances which dissolve or agglutinate animal cells, giving rise to the terms bacterio-hemagglutinin, etc., in distinction to serum-agglutinins. Bacteria may also form other substances of this kind, for example, the staphylococcus forms a staphylohemolysin and a staphyloleucolysin (leucocidin). There is also a specific precipitin which is produced in the serum of an animal immunized with certain micro-organisms; bringing such a serum in contact with the fresh filtrate of bouillon cultures of the microbe in question gives rise to a precipitate (Kraus).

By way of summary, one may say that the products of immunization are antitoxins, antiferments (antirennet, etc.), coagulins and precipitins, agglutinins, and cytolysins or cytotoxins; of these the cytolysins require the united action of two separable substances, amboceptor and complement. Of these bodies, the following allow the production of special antibodies: coagulin, precipitin, agglutinin and cytolysin. An anticytolytic action may be due to the presence either of an antiamboceptor or an anticomplement.

This is surely a complex mass of names and the object of these remarks is solely to call them to mind, but the early confusion disappears for the most part when the principles have been mastered. However, various synonyms have continuously crept into literature, particularly in dealing with the thermostabile body of cytolytic serum. "Antikörper" (antibody), "Immunkörper" (immune body), "Zwischenkörper" (intermediary body), and "Amboceptor" have been applied successively to it by German writers. Bordet and the French school generally use "substance sensibilisatrice" (the substance which sensitizes). However, Metschnikoff introduced "philocytase," then later concluded that "fixateur" represented the function of the body better. We can not conceive what subtle properties the amboceptor may possess by virtue of which London's "desmon" (Gr., a bond) may be better suited than Mueller's "copula" (Lat., a bond). Let us hope we have seen the last in Gruber's "Præparator."

Nor has the complement been spared. Buchner's "alexine" (Gr., to ward off) formerly represented the whole bactericidal property of the blood before specific cytolysis was understood. The French, some Russians and Germans now use it as Ehrlich has used complement, since he abandoned "addiment." Metschnikoff has invented "cytase" out of respect to the supposed cellular (phagocytic) origin of the substance.

In view of the prevailing and growing custom in America, it seems that we are destined to use amboceptor or intermediary body and complement. Amboceptor seems preferable to intermediary body, because the anti- is so conveniently prefixed and the -oid added. As to the state of affairs in Europe, it is to be hoped that the minority will be willing in the course of time to render back their carefully culled but unnecessary names to their source—the lexicon.

LESSONS OF THE EPIDEMIC AT ITHACA.

If the deplorable occurrences at Ithaca are to serve any useful purpose in the economy of nature, it must be to point a moral rather than to adorn a tale. If we

draw lessons for our own behoof from the calamity of other people, it is not with the intent to increase in any way the burden of the afflicted town, but simply with the desire that other municipalities may heed while there is yet time the plainest of the lessons that are taught by the experiences of Ithaca.

The outbreak has already had a remarkable effect in stimulating the authorities of many other towns to inspect and guard more closely their own supplies of surface water. A searching of hearts among the officials in charge of water works is going on all over the country. Clippings come to us all the way from Connecticut to California, showing that municipal water supplies are being looked into as never before. In the city of Buffalo, for example, an active discussion is being carried on at the present moment as to the relative desirability of constructing a filtration plant or pushing the water intake farther into the lake. Rochester, Auburn and many other places in the state of New York are considering measures for the betterment of their supplies. The authorities of several of the large universities are fully awakened, it is said, to their responsibilities, and are increasing the safeguards which are already in some instances thrown about the water supply of their respective student bodies. The wide publicity given by the Ithaca epidemic to the danger that always lurks in an unguarded surface water in a populous district can have no other than a beneficial effect. The constant menace from an unprotected surface water is one of the most obvious of the lessons to be drawn from the Ithaca outbreak.

In some quarters much stress has been laid on the circumstance that the water supply of Ithaca was in the hands of a private corporation, and more or less cogent arguments for municipal ownership have been deduced from this fact. The reversion of opinion on this point at Ithaca is worthy of note: Feb. 27, 1902, the town voted against municipal ownership of the water works by a vote of 718 to 583; while at a special election, held March 2, 1903, the vote stood 1,335 for and only 30 against. There is undoubtedly much to be said in favor of the municipal ownership of public water supplies, and whatever may be one's opinion as to the desirability of municipal ownership of public utilities in general, it must be admitted that the arguments for the ownership of water supply are far stronger than in the case of transportation or illumination facilities. We can not help believing, however, that the introduction of the question of municipal ownership into the present discussion really obscures the true issue. It does not seem to be a question of municipal ownership *per se* that is here in question. Many cities that have owned their water supply for years find themselves in a much more helpless position than Ithaca in respect to controlling the general quality of their supply. It is certainly not true that municipal ownership of water works insures a good supply, or that private ownership necessitates a bad one.

The plain lesson here, and the lesson that, for our part, we should emphasize most strongly, is that both municipalities and private water companies must learn to resort habitually to expert opinion and to accept it when secured. Perhaps the most depressing feature about the management of our cities is the continued failure of the authorities to avail themselves of competent opinion and advice. The good old American custom of assuming that any man's opinion about any matter is as good as any other's, is one that can hardly be carried over into the twentieth century without considerable danger to our national prestige. In matters involving life and health, especially, there is no place for the amateur. City aldermen, college trustees, even physicians without special training in modern hygiene, must all give way eventually to the definitely trained and experienced expert, who can advise with knowledge as to the proper means of safeguarding a water supply or stamping out an epidemic. If those possessed of local authority in such matters would devote themselves to securing precise information concerning the men in whose judgment confidence can be placed, rather than in endeavoring to form for themselves in a few days or weeks an opinion about questions for the proper consideration of which an elaborate and special training is required, the result of their deliberations would be less often either grotesque or disastrous. Reliance on those who know, rather than on those who pretend to know or think they know, is the lesson to be most seriously taken to heart by municipal authorities at the present moment. The requisite information and engineering skill for all public works involving the protection of the public health can easily be obtained, and no fancied exigencies of local or national politics should be allowed to block the way when the lives of human beings are at stake.

A POSSIBLE LEGAL DISTINCTION.

A new question may arise for our technical judges to decide. It is reported that the amended law of North Carolina is so worded as to exempt those "who 'cure' the sick or afflicted by spiritual means alone." It apparently makes no provision for those who only "treat" the sick by such means. As a lay contemporary pertinently asks: "Does it apply in case the patient dies?" The Eddyite or mental healer might find himself still under the law if he had bad luck with his case. It is a little remarkable that the persons who were influential enough to obtain the exemption as stated did not see the possibility of the embarrassing complication. We await the decision of the North Carolina courts with trepidation.

TOTAL ABSTINENCE AMONG BARTENDERS.

A total abstinence society of bartenders has been formed in Chicago, its objects, as set forth, being to promote temperate habits among bartenders, to set a good example to the customers, to protect the cash register and stock, and to elevate the calling. Bartenders are not considered good risks in insurance companies on account of the dangers of their business, there-

fore the promotion of temperate habits among them has a very sensible sort of egoistic motive. To set a good example to the customers, however, by being total abstainers as a business proposition is one which we should think would not be encouraged by the bartenders' employers. It is hardly likely that they would want their customers to become total abstainers. The elevation of the calling is, of course, another question. Whether a calling which discredits itself by the conduct of its own followers can be specially elevated in this way may be a matter of some doubt.

IS SALICYLIC ACID AS A FOOD PRESERVATIVE HARMFUL?

Elsewhere[1] in THE JOURNAL appears an abstract of an article by Drs. MacAlister and Bradshaw of Liverpool, on the effects of salicylic acid as a food preservative. Their conclusions are positive and, as they say, they speak with a due sense of responsibility. According to their views, salicylic acid, in the ways in which it is used in the preparation of food products, is not only not harmful, but is a preservative to health, inasmuch as the process of decomposition which it prevents would be far more dangerous. Their argument seems to be fairly well taken and their experiments reasonably conclusive. They show by their experiments that digestion *in vitro* is scarcely perceptibly hindered by saturated solutions of salicylic acid and that the effects of small quantities on the living subjects are practically negligible, according to their own personal experiences and observation and those of Kolbe, whom they quote. The question of food preservatives is one that is of general interest and the communication, therefore, has a certain specific value. One of their arguments is that a large number of popular non-alcoholic beverages are possible with the use of salicylic acid, and are useful substitutes for the stronger alcoholic drinks. The use of salicylic acid, therefore, is in direct line with the temperance cause. On this point they lay much stress. There is a certain use of salicylic acid to which this argument does not apply, and that is in certain drinks in which a decided percentage of alcohol is used. If the amount of salicylic acid thus taken either in these "temperance drinks" or in the alcoholic ones is not harmful, then it is probably not harmful in food in the way it is used, especially the small quantities in condiments, such as catsup, etc., in which it is principally employed. What is said of the harmlessness of salicylic acid is probably equally true of several other antiseptics used as food preservatives. Dr. Tucker's paper, abstracted in a very recent issue of THE JOURNAL,[2] while conservative as to their use, deprecates any extreme legislation on articles which are not generally conceded to be harmful. It would not be a bad idea, however, as he suggests, to require manufacturers of all substances containing these preservatives to have the proportion used stated on the labels.

1. See page 942 of this issue, abstract 11.
2. THE JOURNAL, March 28, p. 875.

Cocoanut As a Vermifuge.—A diet or a free ingestion of cocoanuts is said, in many of our exchanges, to destroy tape worms. The item is quoted without credit or authority, and the question naturally arises whether the simple remedy is efficient and who has proved it.

Medical News.

DISTRICT OF COLUMBIA.

Georgetown University Hospital Addition.—Ground has been broken for the extension to the Georgetown University Hospital building. The addition will be 100 by 35 feet.

Addition to Garfield Hospital.—Plans are being prepared for the $100,000 addition to Garfield Memorial Hospital, which is to be four stories high and of brick and stone construction.

Law Against Spitting.—After a public hearing, the commissioners have adopted a health regulation prohibiting spitting on the sidewalks. The law already in force prohibits spitting in street cars, public vehicles and public places under control of the district.

Health of the District.—The report of the health officer for the week ended March 21 shows the total number of deaths to have been 111, of which 73 were white and 38 colored; 78 births were reported, of which 50 were white and 28 colored. At the close of the week there were under treatment 86 cases of typhoid fever, 10 of scarlet fever, 8 of diphtheria, and 7 of smallpox.

Medical Inspectors for Schools.—The district appropriation act approved March 3, provides for twelve medical inspectors of public schools, four of whom shall be of the colored race, at $500 each, with the proviso "that said inspectors shall be appointed by the commissioners only after competitive examination, and shall have had at least five years' experience in the practice of medicine in the District of Columbia."

ILLINOIS.

Smallpox at Greenfield.—Dr. Archie W. Barker, Springfield, who was sent by the State Board of Health to Greenfield to investigate the smallpox conditions there, reports that there are twelve cases in the village.

State Society Incorporated.—The Illinois State Medical Society was licensed to incorporate by the Secretary of State, March 24.—The incorporation is not for profit, and the object is to promote the science of medicine. The principal office is to be in Springfield. The incorporators are Drs. David W. Graham, Chicago; Carl E. Black, Jacksonville and Otho B. Will, Peoria.

Chicago.

Practiced Without a License.—Leon H. Dombro, a Russian, was fined $100 and costs, March 23, for practicing medicine without a license.

Generous Pledges.—Dr. Frank Billings announces that one individual has offered to give $100,000 or a large tract of land to the Children's Hospital Society, and that another person has pledged $75,000.

Personal.—Dr. and Mrs. George de Tarnowsky have returned from their trip abroad.——Dr. Horace G Anderson, who has been ill a long time, has been placed in a private sanatorium in Peoria.——Dr. Robert F. Bennett has been adjudged insane and sent to the State Hospital, Elgin.

Bone and Not Lung Tuberculosis.—On account of sensational statements in the daily press regarding the prevalence of tuberculosis in the School for Crippled Children, where it was alleged the majority of the pupils were afflicted with consumption, the health commissioner ordered an investigation, which demonstrated, as might have been expected, that a large proportion of the crippled children were suffering or had suffered from tuberculosis of bones or joints.

The City's Deaths.—The month is barely saving its record as one of declining mortality. The 563 deaths recorded during the week represent an annual rate of 15.58 per 1,000, precisely the same as for the corresponding week of last year, when the death rate was about normal for the season, and 7.9 per cent. lower than that of the preceding week. Pneumonia deaths still continue excessive—100 per cent. greater than those from consumption and 40 per cent. more than last year. The deaths from pneumonia numbered 121; from consumption, 60; from heart disease, 54; from Bright's disease, 33, and from violence, 28.

INDIANA.

Anatomical Board Organizes.—The State Anatomical Board, created by the recent legislature to have charge of the furnishing of corpses to colleges for dissection purposes, held its first meeting in Indianapolis, March 20. Dr. John H. Forrest, Marion, ex-officio chairman of the new board by reason of his position as president of the State Board of Health, presided. The board organized by selecting the following additional

officers: Dr John H. Oliver, treasurer; Dr. E. F. Sommer, secretary; Drs. F. M. Wright, Collins T. Bedford and T. E. Courtney, trustees.

Recent Sanitary Legislation.—The sixty-third general assembly, which adjourned March 7, passed four bills which were presented by the State Board of Health. The first was an increased appropriation for health work. Six thousand dollars per annum, aside from the salary of the secretary and chief clerk, had been heretofore appropriated Now ten thousand dollars is given. This makes an increase of four thousand dollars available Nov. 1, 1903. The state board promises to do good work with this money. The second bill, which became a law, and which the board has twice before recommended, is for the purpose of providing ventilation for the state house. The third forward step gained was the passage of the quarantine law. This law leaves very little more to be desired in the way of power given to boards of health for the suppression of infectious diseases. It first provides that physicians and householders shall immediately report such diseases as are required to be reported in the rules of the State Board of Health. It then becomes the duty of the health officer in whose jurisdiction the disease is found to immediately establish a quarantine "so as effectually to isolate the case or cases and the family if necessary, in such manner and for such time as may be necessary to prevent transmission of the disease." The penalty for breaking quarantine or for physicians refusing or neglecting to "take such precautions as are directed in the rules of the State Board of Health" is a "fine of ten to fifty dollars, to which may be added imprisonment in the county jail not exceeding six months." The law requires that all infected persons and premises shall be disinfected at the proper time according to the rules of the state board. School children, "if infected with any communicable disease, or if they have been exposed to any communicable disease," shall not attend school or appear in public; and all school teachers "shall exclude from the schools all such children, unless a written permit to attend is given by the health officer having jurisdiction." Other important provisions are contained in the law.

IOWA.

Invoke the Law.—Dr. Edwin W. Haradon, Jesup, has been sued by Harry Baker of the same place for $3,000 damages for libel in the form of an information alleging the insanity of the plaintiff——Dr. Edward S. Burroughs, Marshalltown, has been sued by a husband and wife for $6,500 damages; the wife alleging mistake in diagnosis and claiming $5,000, and the husband alleging nothing, but claiming $1,500.

Adulteration Causes Blindness and Death.—A correspondent sends the following extract from the "Waukon Standard," suggesting that the fatal result may have been due to lemon extract made with wood instead of grain alcohol:

> Clarence Floyd, a printer and newspaper writer of Center Point, Iowa, died last week after a protracted period of heavy drinking. Lately he had been unable to purchase liquor, no one daring to sell it to him, but somehow he got hold of two dozen bottles of lemon extract. He drank all but three or four of these bottles and he went blind on the streets of Vinton. Then he grew violent and physicians were summoned. They could do nothing for him and he died in horrible agony.

KENTUCKY.

Jewish Hospital for Louisville.—Jewish individuals and societies of Louisville have already pledged $24,526 of the $30,000 required to establish a free non-sectarian Jewish hospital in that city.

Violated Health Law.—For going to church while suffering from smallpox, Henry Welch, a farmer of Fayette County, was indicted by the grand jury, March 18. This is the first case since the passage of the statute.

Commencement.—Louisville Medical College graduated a class of 53, March 24. General Basil Duke was the orator of the occasion; Dr. John D. Miller of Mississippi delivered the salutatory, and Dr. D. J. Maguire of Kentucky was valedictorian.

Prison for Physician.—Dr. Asa P. Taylor, Lexington, president of a defunct mutual deposit company, was sentenced to three years' imprisonment, March 27, for embezzlement. The offense lay in paying a dividend from the surplus fund of the company.

MARYLAND.

Clean Bill of Health.—Dr. Rohrer, who has been in charge of the smallpox hospital at Chestertown for the past month, released all the suspects and patients there on March 27, and Chestertown now has a clean bill of health

Personal.—Dr. Washington G. Tuck has been reappointed postmaster at Annapolis.——Dr. William W. Golden has been chosen superintendent of the new Davis Memorial Hospital at Elkins, W. Va.——Dr. Henry W. McComas of Oakland has returned from a visit to Hot Springs, Ark. Dr. W. H. Ravenscroft of the same place, who has spent the greater part of the winter in Denver, has also returned.

Baltimore.

Mortality and Morbidity.—The mortality last week was 200, or 16.60 per annum per 1,000 for whites and 37.41 for colored. Pneumonia caused 33 deaths. Two new cases of smallpox were reported, both in negroes.

Damage Suits.—The suit against Dr. Pierre G. Dausch for $20,000 damages for death following operation, has been dismissed on an order of counsel for plaintiff.——A verdict for $100 damages has been obtained against Dr. Arthur D. Mansfield by a woman who claimed that the Doctor pushed her violently while attempting to collect a bill.

The Crim Estate.—The personal property of the late Dr. Crim has been appraised at $48,305. In this is included the large collection of antiques, hitherto mentioned as left in reversionary bequest to the University of Maryland. There are over 1,500 articles enumerated in the inventory, comprising all kinds of furniture and household effects, silverware, paintings, and engravings. The sale of the collection will commence in this city April 22.

Personal.—Dr. Howard A. Kelly will go abroad shortly, to be gone until August. He will attend the sessions of the International Medical Congress at Madrid and will deliver one of the four principal addresses, representing this country. His subject will be "The Passing of a Specialty." He will then go to Glasgow, where he will deliver an address before a medical society, and to Paris, where he will address the French Surgical Society. He will travel extensively through Europe before returning to America.——Dr. Alexander D. McConachie will also attend the Madrid Congress.——Dr. M. W. Glover, U. S Marine-Hospital Service, who has been assigned as medical inspector to the U. S. Immigration Bureau at this port, arrived from New York March 23.

MASSACHUSETTS.

Homans Memorial.—A meeting memorial to the late Dr. John Homans was held in Sprague Hall, Boston, March 30. Addresses were made by Drs. Richardson, Cabot, Shattuck, Bradford, Edes, Warren and Harrington.

Corey Hill Hospital.—Dr. Joel E. Goldthwaite, Boston, has joined with twelve other Boston medical men and will erect on Corey Hill a fine hospital, to be called the Corey Hill Hospital. It will accommodate about thirty patients and be modern and complete in all its details.

Lowell Typhoid Traced.—The health department of Lowell has traced the typhoid fever which is prevalent there to the milk supplied by a Chelmsford milkman, whose hired man was ill with typhoid. The local authorities have interdicted the delivery of milk from this source in Lowell.

Brigham Hospital.—The new buildings of the Brigham Hospital are to cost more than $1,000,000, and the income will be about $150,000 annually. This will be administered by a board of twelve directors recently chosen by the corporation which is styled The New England Trust Company.

Massachusetts General Hospital Staff.—Drs. James C. White, William L. Richardson, and C. B. Porter, who recently resigned from the visiting staff of the Massachusetts General Hospital, have been appointed members of the consulting staff. Dr. James J. Minot has been appointed visiting physician.

Formalin and Bacteria.—The tests made by Dr Hibbert Winslow Hills, bacteriologist of the Boston Board of Health, on the value of formalin injections to arrest bacterial activity in the body as advocated by Dr. Barrows, indicate that solutions to be efficient must be sufficiently strong to destroy tissues and hence are impracticable.

Unregistered Practitioner Sentenced.—Henry Beltman, who came to America from Germany only a year ago, was sentenced to three months in jail as he was unable to pay a fine of $100 assessed against him for practicing medicine without being registered according to law. He pleaded for leniency, claiming that he ignorantly infringed the law.

Ten Hours a Day Limit for Nurses.—A bill before the state legislative committee on labor provides that nurses and attendants in hospitals, asylums and sanatoriums shall not be

required to be on duty more than ten hours in the twenty-four, and that if emergency requires such service, corresponding time off during the ensuing week shall be allowed.

Bequests.—Arioch Wentworth, whose fortune is estimated at over seven millions, left $100,000 to the town of Dover, N. H., for a hospital to be called The Wentworth. The bulk of his estate is to be used in the establishment and maintenance of a great trades school.——The will of J. H. Center, Boston, leaves $54,000 to charities, prominent among which are the Massachusetts Homeopathic Hospital, Children's Hospital, House of the Good Samaritan, and the Massachusetts Charitable Eye and Ear Infirmary.

MICHIGAN.

From Murder to Manslaughter.—The charge of murder against Dr. Wallace E. Newark, Charlotte, on account of his implication in the death of Mrs. Harriet Wirtz, has been changed to manslaughter, and his bail reduced from $2,500 to $1,500.

To Muzzle Dogs.—The Michigan State Board of Health has issued a circular recommending that every local board of health immediately make and publish regulations ordering the muzzling of all dogs at large and the killing of all unmuzzled dogs found at large, and that provision be made for the prompt and effective execution of such regulations.

No Isolation Hospital.—At the session of the Detroit city council, March 28, the proposed appropriation of $75,000 for a city hospital for communicable diseases was cut out of the estimates for the year. Drs. Guy L. Kiefer, Johnston B. Kennedy and Charles G. Jennings argued for the hospital, and Dr. J. Henry Carstens opposed and prevailed.

University Treats Hydrophobia.—The Board of Regents of the University of Michigan, at a recent meeting, decided to provide Pasteur treatment for hydrophobia, and appropriated $2,500 for the purpose. Residents of Michigan will be treated free, while patients from other states will be charged what they would have to pay at a private institution. Dr. Thomas B. Cooley, a graduate of the medical department of 1895, will have charge of this work under the supervision of Dr. V. C. Vaughan, director of the hygienic laboratory.

MISSOURI.

Quigg Bill Defeated.—The bill to create four boards of examiners, one for each of four so-called schools of practice was defeated in the house.

Osteopathy Bill Passed.—Both houses of the legislature have passed the bill regulating the practice of osteopathy and providing therefor a state board of examiners, and the bill now requires only the governor's signature to become law.

New Blind Asylum.—The legislature has passed the bill authorizing the sale of the asylum for the blind property in St. Louis and the purchase of a new site. The bill carries an appropriation of $150,000. Under the provisions of the bill a commission of three will be appointed by the governor to take charge of the matter.

Commencements.—On March 24 Kansas City Medical College graduated a class of 24. Chancellor E. Benjamin Andrews of the University of Nebraska delivered the address to the class. ——Medico-Chirurgical College, Kansas City, awarded diplomas to a class of 20, March 19.——The graduating exercises of the University Medical College, Kansas City, were held March 26, when a class of 63 was graduated.

College Merger.—On May 1, 1903, St. Louis University assumes control of the Marion-Sims-Beaumont College of Medicine, which becomes the medical department of the university. St. Louis University founded the pioneer medical college of the Mississippi Valley in 1836; in 1855 its medical school became independent of the university. The revival of its medical school by the acquirement of the Marion-Sims-Beaumont College is a step in the development of the university, and of great importance for the progress of medical teaching in St. Louis.

NEW YORK.

Surgical Pavilion Opened.—The Cochran Surgical Pavilion, an annex to St. John's Riverside Hospital, Yonkers, provided at a cost of $55,000 by the late William Francis Cochran, was thrown open, March 21.

One-Fourth Consumptives.—In an argument before the legislative committee on ways and means by Dr. Julius B. Ransom, physician to the Clinton State Prison, Dannemora, he stated that one-fourth of the population of the prison is afflicted with tuberculosis.

Nursery and Child's Hospital Bill Unconstitutional.—A bill now before the legislature authorizing the sale of the property of the Nursery and Child's Hospital has been declared unconstitutional by Attorney-General Cunneen. The hospital holds the property under a perpetual lease from New York City, and in view of the encroachments necessitated by the proposed extension of the terminal facilities of the New York Central and Hudson River Railroad the managers of the hospital are anxious to sell the property and purchase another and more suitable site. The legal opinion says that the authorities of New York City might be empowered to effect the sale.

New York City.

Nurses' Home.—The Presbyterian Hospital is about to erect a magnificent six-story home for its nurses. The structure will be located in East Seventy-first Street, near the hospital, and is to cost $300,000.

In Memoriam.—The alumni of Charity Hospital, Brooklyn, at a special meeting held March 11, adopted resolutions of regard, regret and sympathy on the death of Dr. Earle Woolworth, who was an interne in the hospital in 1897.

Decision Favors Faith Healers.—The Appellate Division of the Supreme Court in Brooklyn has reversed the conviction of J. Luther Pierson of Valhalla, the charge being a failure to provide a physician for his adopted daughter. Judge Bartlett wrote the opinion, which was concurred in by Judges Hirschberg and Jenks. Presiding Judge Goodrich, in dissenting from this opinion, maintained that liberty of conscience should not justify practice inconsistent with the peace and safety of the state.

Tents for Tuberculous.—The president of the department of health has written a letter to the mayor regarding this subject, from which the following excerpts are taken:

During 1902 7,571 persons died of tuberculosis of the lungs in New York City, while 1,312 died of other forms of tuberculosis. In 1901 the deaths from pulmonary tuberculosis numbered 8,135. While the death-rate from tuberculosis was thus gratifyingly reduced in 1902, the disease remains the greatest single cause of deaths in this city. I believe that with an appropriation of $35,000, which amount will be formally requested by the board of health from the board of estimate and apportionment, I can erect a sanatorium on the tent and ducker plan, with accommodations for sixty patients and fifteen attendants, to be operated from May 1 to Dec. 31, 1903. If this camp should be put in operation and should prove to be successful, as I do not doubt it will, it will then be possible for the city of New York to enter on this method of tuberculosis prevention on a larger scale.

A tract of ninety acres in Orange County, N. Y., has been offered to this department free for a period of two years, and the acceptance of the offer entails no financial obligations on the city.

The extreme cheapness of the tent plan for the care of tuberculosis cases, as compared with the hospital plan, leads me to believe that if the work is taken up under the auspices of the New York City government it will be adopted by many other cities of the United States.

PENNSYLVANIA.

To Enlarge Hospital.—It is proposed to enlarge the Bryn Mawr Hospital and subscriptions are being secured for this purpose.

Smallpox on Steamer.—The British steamer "Riverdale," on its arrival at Delaware Breakwater, signaled that smallpox had broken out among the crew. The vessel was taken charge of at Reedy Island Quarantine.

Hospital for Allegheny.—Allegheny is soon to have a general hospital. The main building will be seven stories high, and there will be separate one-story buildings for contagious diseases and for a laboratory and autopsy room.

Hospital Bill Passed.—A bill passed by the legislature and recently signed by the governor gives municipalities the right to acquire property, either within or without their limits, on which to erect hospitals, or for the purpose of waterworks or for poor-farms.

Philadelphia.

Hospital Staff Change.—Dr. David D. Stewart has resigned as visiting physician to the Protestant Episcopal Hospital and Dr. Charles H. Weber has been appointed to the place.

Phototherapy at the Polyclinic.—The Polyclinic Hospital has established a phototherapeutic department and will treat without charge a limited number of appropriate and deserving cases.

Health Report.—The official health report for the week ended March 28 shows a decided decrease in the number of new cases of typhoid fever, there being only 154 new cases, as against 247 for the previous week. There was an unusual number of new cases of diphtheria and scarlet fever, 54 of the former and 94 of the latter. There were 31 new cases of smallpox. The general mortality was high.

To Raise Standard.—At the regular meeting of the Philadelphia County Medical Society, March 25, a resolution was adopted urging the passage by the legislature of the Ray bill, now before the senate. The bill provides for higher preliminary requirements for those entering medical colleges. One provision of the bill, which took away a privilege now accorded students of smaller colleges of good standing, namely, that of entering the second year of medical college by showing an equivalent for the first year has been amended in the senate so as to retain the original privilege.

GENERAL.

Plague at Hawaii.—Two cases of plague were reported from Hilo, Hawaii, March 17.

More Plague at San Francisco.—After being free from any report of plague for many weeks, San Francisco has had one more case; this was in a Japanese woman, who died in the week ended March 21.

Examination for Army Medical Corps.—The examination will be held at the Army Medical Museum, beginning April 20, to fill forty vacancies in the junior grade of the medical department of the Army.

Florida Postpones Quarantine.—Every spring it has been a precaution of Florida to declare a quarantine against Cuba through fear of yellow fever. This year no quarantine will be enforced until cases of yellow fever occur in Cuba.

The Fourth Pan American Medical Congress, which was to have been held this year in Buenos Ayres, Argentine Republic, will not be held there on account of some unforseen complications It has practically been decided to hold the next meeting in Toronto, Canada, September next.

Vacancies in Navy Medical Department.—There are twenty-seven vacancies in the grade of assistant surgeon in the United States Navy. General Van Reipen and Surgeon-General Rixey are exerting every effort to fill the vacancies with young medical graduates of marked ability.

The Navy Medical School will hold its graduating exercises April 4. The following assistant surgeons will graduate at that time: Drs. R. A. Backman, E. M. Brown, R. E. Hoyt, M. W. Baker, J. L. Neilson, H. Shaw, F. M. Munson, H. F. Strine, J. P Trainer, J. H. Holloway, R. H. Michels and B. F. Jennings.

Promotion of Naval Medical Officers.—The acting secretary of the Navy has decided officially that medical officers of the Navy must, under the law, be promoted to the next higher grade as line officers of like dates of precedence are promoted. In promoting medical officers they are to be advanced grade by grade with such line officers.

Whiting Caught.—We are glad to announce that F. Whiting, who was swindling physicians in Pennsylvania, New York and other eastern states, has been arrested, convicted and is now serving a six months' jail sentence. Credit is due to Drs. J. W. Morris, Jamestown, N. Y.; F W. Frankhauser, Reading, Pa., and C. G. Hubbard, Hornellsville, N. Y., in securing Whiting's arrest and conviction. We can not allow this opportunity to pass without again urging our readers never to pay money to agents of any journal, or, in fact, to agents of anything, unless they show written and undoubted authority to make collections. Some two years ago a smooth young man swindled a large number of physicians, keeping up for several months by claiming to represent one journal for a while, then another and another, changing his name and field of operation with each change in journal.

CANADA.

Appointment.—The board of governors of McGill University have appointed Dr. James M. Elder of Montreal, assistant professor of surgery and lecturer in clinical surgery in the medical department of McGill.

Ghoul's Work at Queen's University, Kingston.—A freshman of Queen's University has recently been placed under arrest, having been caught in the act of attempting to rob a grave in a cemetery near that city.

Physicians to Speak in Montreal Churches.—The Protestant Ministerial Association of Montreal has decided that meetings should be held in all the city churches in May, at which addresses will be given by city physicians on "Tuberculosis and How Best to Prevent its Spread"

Canadian Physicians Turned Down in South Africa.—Three Canadian physicians, who went to South Africa with the Canadian Army medical corps, tried, at the conclusion of the war, to practice in the Transvaal. They were prohibited from doing so because only English diplomas were legal there They appealed to Lord Milner, but he refused to alter the regulation.

New Isolation Hospital Site Selected in Montreal.—The site of the new contagious diseases hospital, which is to be conducted under the management of the authorities of the Notre Dame Hospital, has been secured. The piece of land contains 52,000 feet and cost $15,000. The board of management of the hospital is to receive $15,000 annually from the city council for the purpose of maintaining the institution.

Honoring Dr. William Bayard, St. John, N. B.—A tribute of public regard and personal esteem was recently tendered to Dr. William Bayard of St. John, one of the oldest medical men in Canada. It took the shape of a handsomely engrossed resolution on parchment and was presented by the municipal council of St. John on the occasion of Dr. Bayard's resignation from the board of commissioners of the General Public Hospital, after a service of forty years

Medical Inspection of Schools in Montreal.—In a paper recently read before the social science department of the Women's Club, Montreal, Dr. C. H. Church of that city strongly advocated the medical inspection of the schools of Montreal, as the conditions existing in some of them are to the last degree dangerous and unsanitary. Dr. Church had recently made an inspection of some of the city schools and the conditions he found prevailing, as embodied in his paper, seem almost to be incredible in a city the size of Montreal.

Deaths from Scarlet Fever in Ontario.—The returns for Ontario for February show a great number of deaths from scarlet fever. There were in all 104 deaths from this disease as compared with 38 during February, 1902. In January there were 94 deaths from scarlet fever, so that this year already there have been over 200 deaths from this disease. The deaths in Ontario in February from other diseases were: smallpox, 4; diphtheria, 27; measles, 7; whooping-cough, 7; typhoid, 19; tuberculosis, 160; total deaths, 2,083.

Growth of Montreal Tuberculosis League.—The Montreal League for the Prevention of Tuberculosis is rapidly growing in importance. It is now virtually associated with the main body, which holds its annual meeting at Ottawa, April 16. Dr. Roddick, as chairman of the executive, and Dr. Richer, secretary, will represent the league officially; and Senator Drummond, president of the league, Professor Adami and Dr. Lachapelle will also be present. Dr. Lachapelle will shortly present a strong resolution to the City Council, recommending that a by-law be passed against the obnoxious habit of spitting in public places.

Academy of Medicine and Physicians' Club for Toronto.—A movement is now on foot in Toronto looking to the amalgamation of the Toronto Clinical Society, Toronto Medical Society, Toronto Pathological Society and Ontario Medical Library Association into an Academy of Medicine and the establishment in connection therewith of a physicians' club. The movement is being endorsed by prominent practitioners in Toronto; and it is understood that already negotiations are under way for the purchase of a very handsome residence in the very heart of the city. The movement is a very desirable one, and it is to be hoped will meet with full consummation.

Ontario Medical Association.—The annual meeting of the Ontario Medical Association will be held in Toronto, June 16 to 18, under the Presidency of Dr. J. C. Mitchell of that city. This will be the first time in its history that a three days' meeting has been deemed advisable. The chairman of papers and business is Dr. W. P. Caven, Toronto, while Dr. Bruce Riordan, Toronto, will have charge of arrangements. This will ensure success both socially and scientifically. Dr. Thos. Cullen of Baltimore and Dr. Musser of Philadelphia are to be present and contribute papers During the meeting a discussion will be held on arteriosclerosis. Dr. Harold C. Parsons, Bloor St., W. Toronto, is the general secretary.

FOREIGN.

Another Hospital Bed at Nice.—H. Humphrey Moore of California has established an American bed in the Victoria Hospital at Nice.

Veit Goes to Erlangen.—Professor Veit of Leyden has accepted a call to Erlangen to the chair of obstetrics and gynecology, in the place of the late Professor Gessner.

Legacy for Neurasthenics in Norway.—A legacy from the Meyer family of Bergen, Norway, leaves over $75,000 to be applied to the assistance of neurasthenics. Part of the fund is for children.

Measles in London is more fatal than in previous years. It is not on the list of reportable disease in many sections of England. In view of its greater severity, English physicians are urging that it be made reportable.

Personally Conducted French Medical Trip to Foreign Universities.—The "Presse Médicale" of Paris has organized several of these tours and is now arranging one to visit the universities in Spain on the occasion of the International Medical Congress.

The Tenth Congress of Polish Physicians and Scientists, which was to meet in Lemberg, Austria, July, 1903, has been postponed until July, 1904, on account of the several international meetings which have either taken place recently or will occur during the current year.

Schaudinn Receives the Tiedemann Prize.—Dr. F. Schaudinn of Berlin has been awarded the annual Tiedemann prize by the Senkenburg Society at Frankfurt a. M. for his biologic studies and monograph on the Coccidia. The prize consists of a medal and $125. The previous recipients have been Koch, Bütschli, Ehrlich, E. Fischer, Behring, and A. Kossel.

England Fears Sleeping Sickness.—The question is asked in London whether or not the so-called sleeping sickness of Africa can be transmitted to England by returning soldiers and, if so, how the danger should be handled? The disease has been known for years, but only as a rarity. Its change to an epidemic excites alarm, it is said, lest its nature be such as to threaten other than African or even other than tropical countries.

Novel Cure for Baldness.—A Weimar quack prescribed as a cure for baldness to smear the head with plum jam and spend three days and nights in the cellar. The farmer who followed his directions had a fine growth of mould by the third day, which was claimed to be the new growth of hair. But the course of treatment was interrupted by a severe cold, which kept the man in bed for three weeks. He complained to the authorities and the quack was fined $1.25.

Memorial to Panas.—The friends of the late eminent Paris ophthalmologist are soliciting subscriptions for the purpose of erecting a portrait bust of Panas in the large hall of the ophthalmic clinic where he lectured for twenty-two years. A medal is also to be struck, and all who subscribe at least $5 will receive a duplicate of the medal. Subscriptions can be sent direct to the bankers, MM. Rodocanachi et Cie, avenue Gabriel 42, Paris, or to the secretary, Dr. Monthus, rue Godot-de-Mauroi 41.

Quarantine Mecca Pilgrims.—Egypt is inspecting the caravans of pilgrims that are on their way to Mecca. Tor is a small port near Mount Sinai where each pilgrim has to stop and be investigated and have his belongings fumigated. Quarantine is established whenever there is need. The government pays the expenses of pilgrims who are detained. All boats are compelled by inspectors to carry pure water and to use wholesome food. The inspectors have the right to levy fines for infractions of rules and to detain vessels until such fines are paid. Since many pilgrims are sick or feeble and make the pilgrimage for that reason, hoping thereby to insure a right to paradise, the mortality and spread of disease is great. It is estimated that a third of those who start perish in the hardships of the desert.

Professional Secrecy Conflicting with Notification of Diseases.—The proposal to have notification of the venereal diseases made compulsory, which was discussed at the Preventive Conferences, is energetically combatted by Boulengier in an appeal to the "Presse Méd. Belge." He complains that the physician is being deprived more and more of his personal initiative, and being degraded into a mere police official. People at large are like great children. Much more can be accomplished by gentle moral suasion and example than by compulsion. What is needed is better training of medical students in the diagnosis and treatment of venereal diseases, special diplomas for specialists in this line and a "practical year" in venereal practice, with repeated post-graduate courses, which should include lectures on medical ethics. All public medical officials should be compelled to attend these courses. Unna's journal quotes his article approvingly.

German Society for Campaign Against Quackery.—A society has been recently organized for this purpose at Berlin with a large membership of physicians and laymen belonging to all classes of society. The aim of the organization is to enlighten the public in regard to the damage inflicted on health and purse by the practices of charlatans, and also to instruct the public in the proper care of the sick. Public lectures on both subjects are to be held, and examples of the damage done by quacks will be cited. Still another line in which the society hopes to accomplish much is to send delegates to the open meetings held by charlatans to take part in the discussions. Popularly worded pamphlets warning the public are also to be distributed, and the publication of a weekly journal to further the cause is contemplated. Flagrant cases of injury from quack practices are to be reported to the officials and daily press. The dues of the society are merely 25 cents a year, and the list of members already includes many prominent names, both in and outside of the profession. Dr. Siefart of Tauenzienstrasse 3, Berlin, is the treasurer. The first public meeting was held March 8 in the city hall. The charlatans and their adherents were there in full force and by their demonstrations rendered the proceedings rather noisy.

Semi-Centennial of Munich Med. Wochenschrift.—At the jubilee banquet, March 7, Dr. Merkel reviewed the history of the "Wochenschrift," which is practically the history of medicine in Bavaria. The history of the medical press in general from its earliest inception was reviewed by Dr. Sudhoff, the most complete historical sketch of this subject yet produced. Both of the addresses are to be published in the "Wochenschrift." A bust of Dr. Dollinger, who has been managing the weekly, was unveiled, and a painting and set of silver were presented to the publisher and editor-in-chief. A reproduction of the first number of the "Wochenschrift" under its primitive title of "Aerztlisches Intelligenz-Blatt," was distributed to the 160 guests. It was announced that the number of subscribers is now 9,000 and that the balance on hand for distribution to worthy objects was $3,850 Of this sum $1,230 was given to the National Physicians' Insurance Fund, $500 to the Fund for Widows and Orphans of Bavarian Physicians, and other sums to similar organizations, with $1,250 to the Pettenkofer Memorial Building Fund, $25 to the Haller Monument Fund in Berne, and $125 to the Ziemssen Memorial Fund. This makes a total of nearly $12,000 distributed for such purposes since 1897. The "Wochenschrift" has been published by a syndicate of ten physicians, to which Helferich of Kiel and Spatz of Munich have recently been added.

Campaign Against Charlatans in Germany.—The last "Allg. Med. Ct.-Ztg." reports five new successfully prosecuted suits against quacks in Germany. The Hanover court condemned L. Fette to four years at hard labor and a fine of $375 for his swindling methods, selling a box of salve that he bought in the drug stores for 10 cents for $3 to $5, and similar frauds. The Bayreuth court condemned Ahrbecker to two years of hard labor for selling abortifacients, and another charlatan, Jacob, to one month's imprisonment for receiving and treating by his methods a man with a complicated and soiled fracture of the leg, until the man was in the last stages of sepsis, when he summoned a physician. The Detmold court also condemned a magnetopath to six months in prison for treating an incarcerated hernia as "stomach cramps" until too late for suitable aid to be effective. Another magnetopath, Vigano, has also been sentenced to two years of prison at Magdeburg. It was found that he used to stand on a metal plate in the floor, connected with an electric apparatus, so that his patients could actually "feel the magnetic sparks emanating from him" as he touched them. He treated gallstones with an "oil cure," and presented the patients afterward with pebbles which he announced that they had voided. The testimony showed that the office boy ran out to pick up the pebbles as needed. He frequently received from $15 to $20 for a course of this treatment.

LONDON LETTER.

The Eyesight of School Children.

For some time the London School Board has had under consideration the question of the eyesight of the children and the means to be taken for its preservation when defective. As a result it has been decided to appoint 6 oculists. The general result of a preliminary test showed that while 80 per cent. of the children in the schools were found to have normal vision and 10 per cent. fair vision, the sight of 10 per cent. was bad, and of these 2 or 3 per cent. were very bad. Such defects of vision as existed were not due chiefly to fine work or bad lighting in the schools, but to social and nutritive conditions and to racial peculiarities, the proportion of those who had very bad sight being larger in the poorer schools than in those which were well-to-do, and larger in those schools which were predominantly Jewish than in those which were mainly Christians. The recommendation of the medical officer was that in future every child, when first admitted into a senior depart-

ment, should be examined by the class teacher, and a vision record made, such test being repeated annually.

The Anatomy of the Skull Stereoscopically Demonstrated by the X-Rays.

At the Royal Academy of Medicine in Ireland Dr. W. S. Houghton pointed out that the difficulty of interpreting a single skiagram arose from several causes. The *x*-ray picture was an example of uniplanar projection of multiplanar objects. This caused superposition of shadows. Then the fact that the *x*-rays formed a diverging cone caused magnification and obliquity distortions. These sources of inaccuracy in the "single picture" were eliminated by the beautiful stereoscopic method of Roentgen photography of Mr. Mackenzie Davidson. By this method a reproduction of the skull could be obtained, perfect in contour and perspective. Dr. Houghton showed by diagrams how all sources of inaccuracy were eliminated in the stereoscopic method and afterwards in the reflecting stereoscope showed prints of the base of the skull and lateral views in which general points were well demonstrated, including the relations of the groove for the lateral sinus to the mastoid air cells, the mastoid emissary vein, the internal auditory meatus, the external auditory meatus, the cochlea, the semicircular canals, the canal for the internal carotid artery, and the foramina in the base of the skull.

The Physical Condition of School Children.

The physical deterioration of the town population, which ever increases at the expense of the country, has given rise to serious forbodings by those interested in the national welfare. A royal commission appointed to inquire into the physical training of children in Scotland has just presented its report. The principle that education should consist in training the body, as well as the mind, though acted on in the schools of the upper classes and in the universities, is systematically ignored in the state-provided schools for the mass of the population. The commissioners ask for a more comprehensive conception of school life than prevails, and provision of larger playgrounds and exercise halls. They consider that too many subjects are attempted to be taught and that the children are too closely confined to their books. Systematic school exercises are recommended. At present in the schools in Scotland only from half an hour to two or three a week are devoted to physical training. The commissioners have collected some rather alarming statistics concerning the prevalence of diseases of the eyes, ears, nose and throat.

Paraffin Injections in Prolapse of the Bowel and Uterus.

At the Clinical Society Mr. Stephen Paget read a paper on this novel method of treatment. He described the case of a man aged 65 who in 1897 underwent excision of the rectum for cancer. Ever since he suffered prolapse of the bowel and was compelled to wear a rectal plug. On January 15 paraffin was injected into the prolapse bowel, forming two round, hard nodules under the mucous membrane, so that the orifice was closed by a sort of valve. The prolapse was cured and the use of the plug discontinued. In another case a woman aged 70 had suffered from prolapse of the bowel for 22 years, and had undergone 5 operations. Prolapse occurred on the slightest effort, and if the motions were very loose she had no control over them. On February 15 paraffin was injected under the mucous membrane and formed a hard collar, more than half of the bowel. This produced great improvement, but still slight prolapse at times. March 1 a second injection was made and the anal orifice was narrowed by Mayo-Robson's operation. The prolapse was permanently cured. In a third case a woman aged 63 had for 28 years suffered from prolapse of the uterus, in spite of an operation performed 14 years before. The vagina was so dilated that it would not contain a pessary, and there was complete prolapse of both walls and of the cervix, which was greatly enlarged. Paraffin was injected in various directions under the mucous membrane of the vagina, mostly in the posterior wall and under the mucous membrane of the cervix. Since then there had been no prolapse, not even when she strained. The cervix was high, and both vaginal walls were indurated, and the recto-vaginal septum was half an inch thick.

As to Prognosis.—Never be too sure. Be not over-positive. A wrong prognosis is always bad—for the doctor. One that is conservative and guarded is always safe for the reason that it permits one to turn either way in modification of the former contingent opinion, and thus always be right.—"Med. Council"

Correspondence.

Pompeii and the Alleged Lost Art of Gynecology.

Barry, Ill., March 21, 1903.

To the Editor:—Enclosed please find an article which appeared in "Current Literature" of December, 1900, based as to the knowledge alleged to have been in existence in the time when Pompeii was in existence, that is, before 770 A. D., on an article in the "Scientific American." I saw, some weeks ago, in the "Sunday Globe-Democrat," the same statements, only stronger. I mislaid the copy which I intended to send you at that time, but, fortunately, while looking over some old numbers of the "Current Literature" I find the enclosed.

[The enclosure credits the Pompeiians with having a great number of surgical instruments the exact counterpart of those used to-day and further declares that gynecology in its present degree of perfection was existent 2,000 years ago.]

Now, I do not believe a word of the statement for two reasons: If such were a fact, it would be very strange if no hint of the kind is to be found in the works of the Elder Pliny, who perished in the eruption of Vesuvius which destroyed Pompeii, he being in command of the Roman fleet stationed in the Bay of Naples. His works are well known to contain a hodge podge of almost everything known at that time which by any possibility could be considered at that time as belonging to natural history and a great deal that has no sort of relation thereto. But if it should so happen that he does not deal in medical and surgical knowledge, my second reason is much stronger, for, as you know, we have what the Encyclopedia Brittanica,, vol. 23, p 675, calls the "Authoritative Treatise of Paul of Argina, 650 A. D.," which contains no mention of any such wonderful instruments. I suppose that the translation by Travis Adams, 3 vols., London, 1847, is easily to be found in some of the Chicago medical libraries. I think if I am right that The Journal ought to have an article on the subject. I should think that Dr. Senn might well occupy some of his learned leisure, if he has any at this time of year, in writing such an article; it ought to be illustrated by pictures of those wonderful "anticipations" by the ancients of the proudest achievements of modern surgery.

E. W. Baker.

Answer.—There is a popular superstition that there are lost arts; that in times past the earlier civilizations excelled the efforts of our times. Wendell Phillips used to have a favorite lecture which he delivered through the country on these lost arts, which may have been a partial cause of the prevalent notions on the subject. The fact is, however, that there is no lost art. Whatever was lost during the middle ages has been more than recovered. Dr. Senn's paper on Pompeiian surgery and surgical instruments, "Medical News," Dec. 28, 1895, which seems to be unknown to our correspondent, while it illustrates surgical instruments obtained at Pompeii, gives no evidence of anything to compare with the imaginations of the writer of the article in "Current Literature" referred to by Dr. Baker. The instruments Dr. Senn illustrates are crude and, while they seem to suggest in some respects modern appliances, etc., they are very far from being what a surgeon of the present day would care to be restricted to in his surgery, and a very poor mechanic at the present time could improve on them. As the late Prof. Joseph Henry used to say, there is no lost art except that of reckless and unlimited waste of human life, to which many of the great works of the ancients, as now shown in the ruins of Baalbec and in the Pyramids, can be attributed. Human life and time counted for little with the despots of the Orient in the early history of the world.

Osteopaths and Legislation.

New York, March 28, 1903.

To the Editor:—It seems incredible that the osteopaths should have been enabled to gain favorable legislation in several states, and it makes one feel that the physicians have not properly presented the matter in discussions before legislative

committees. On several occasions when I have been present it was painfully evident that regular physicians who were being depended on by members of the committee had not read any of the books or other literature of the osteopaths, and that they were not prepared to take a dignified position in discussions. It seems to me that the osteopaths could always be defeated without the necessity for any very elaborate argument if some physician would take the trouble to have properly-prepared specimens of spinal columns to show to members of the committee. I have chosen a longitudinal section of a child three or four years of age, preserved in formalin solution, and the fresh rack of a lamb. The osteopaths are then asked to state that they cure diseases by "setting or moving" vertebræ and ribs and other bones, and the fraudulent nature of their pretension is so apparent to legislators who have the specimens before them, that even as laymen they are at once convinced of the deception that is practiced on patients, and one need not turn any fine points in rhetoric, or polish his diction in preparation for the discussion. There is one point in osteopathic bills that is misleading to legislators. I quote from this year's New Jersey Senate Bill No. 218, Page 4, Section 9: "The certificate or license granted by said board shall not in any way be construed to authorize the holder thereof to prescribe or use drugs in his or her practice, nor to perform operative surgery." This sounds very innocent, but it means that osteopaths will take charge of all sorts of cases that really should have the benefit of drugs or of operative surgery.

58 West 56th Street. ROBERT T. MORRIS.

Priority in Technic of Tubercle Bacilli Recognition.

CHICAGO, March 30, 1903.

To the Editor:—In your issue of March 28, I notice an abstract of a paper which appeared in the "Deutsche Zeitschrift für Chirurgie" by Forssell on an "Improved Method of Determining the Presence of Tubercle Bacilli in the Urine."

I would direct your attention to the fact that the process described is identical in every essential feature with the method introduced by Dr. J. E. Skinner and myself a number of years ago and described by us in an article published in THE JOURNAL of the American Medical Association, Jan. 29, 1898. Our process, as described in this paper, consists in separating the sediment from a considerable volume of urine by gravity (preferably in a tapering glass vessel like a percolator), drawing off the deposit, and reducing it to a very small bulk by centrifuging. Forssell's method, as will be seen by consulting the abstract referred to, is practically identical with this.

It is true that our method was especially devised and introduced for the purpose of detecting casts in the urine, and this fact is indicated in the title of our article. But in two or three places we refer to its use in examining for any sediment, and in next to the last paragraph we speak of its great advantage in testing urine for micro-organisms, especially when they are sparingly present.

I may add that I have used the method now for six or seven years and find it fully as advantageous as claimed in our article for the detection of casts and all other sediments when present in small proportion, and I am glad to have the added testimony of Forssell in regard to its value in examining for tubercle bacilli WALTER S. HAINES.

A Vigorous Protest.

CHICAGO, March 30, 1903.

To the Editor:—I wish to protest as vigorously and publicly as may be against the sentiment, the lack of good taste, the apparent deplorable motive, and the contents of the editorial with the Latinized caption, on page 855 of the last issue of THE JOURNAL. This poorly conceived, libelous and anonymous assault on the scientific labors of Dr Jacques Loeb, and on his personal character, does not add dignity to THE JOURNAL, nor is it calculated to cultivate respect for the Association among the many students of this pioneer in physiology. I have read it with shame and disgust, and I call for a public apology from the censorial editor of his flagrant neglect of duty. BAYARD HOLMES, M.D.

ANSWER.—A careful reading of our editorial will, we think, convince one that our critic is over-sensitive in his interest in the eminent physiologist referred to. It was not intended to reflect in any way on his personal character or scientific work, but to criticise the unfortunate—to say the least—sensationalism which has attended most of the announcements of his discoveries in the public press, and to notice the latest statements credited to him which seem to be extreme and scientifically presumptious. We do not think an apology is called for.

The Sub-Section on Tropical Medicine.

NEW YORK, March 28, 1903

To the Editor:—Allow me the observation that tropical medicine is of such vast importance that a sub-section as proposed by you and which you editorially endorse would not cover the ground. Why should the Section on Hygiene and Sanitary Science have anything to do with it? That section has as much interest in every other section as it would have in tropical medicine. ALBERT S. ASHMEAD.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of, the writer not to publish his name will be faithfully observed.

WHY IS THE A. C. E. MIXTURE NOT USED MORE?

MAHONY CITY, PA., March 23, 1903.

To the Editor:—Dr. Willy Meyer (in THE JOURNAL of February 28 and March 7) quotes our English colleagues as having used the A. C. E. mixture in 15,000 cases without one death. If this is true kindly advise me why the A. C. E. mixture is not used more in this country. GEORGE W. REESE.

ANS.—The A. C. E. mixture has never achieved the popularity in this country that it has in England. We believe it is used there more than is either ether or chloroform. Deaths are, however, reported from its use.

MADRID CONGRESS RAILROAD CERTIFICATES.

NEW YORK, March 25, 1903.

To the Editor:—The following information has just been received by cable from the Secretary-General of the Fourteenth International Medical Congress: The French railroads have made their rate reductions for the members of the International Medical Congress depend on a special certificate, and on the use of the same route for going and returning. Any member of the congress to whom this is of interest should therefore write immediately to the secretary-general at Madrid, stating at what port he expects to land and what route he will take. The secretary-general will send to him at the port named under the address "poste restante" the necessary certificate. JOHN H. HUDDLESTON,
Secretary American Committee.

MATERNAL IMPRESSIONS.

ATCHISON, KAN., March 26, 1903.

To the Editor:—In THE JOURNAL of March 21, Dr. A. G. Beisheim reports a case of so-called maternal impression. The Doctor evidently wishes to convey the inference that the burn was responsible for the birthmark.

The maternal-impression belief is as old as the race and apparently as ineradicable as the unlucky Friday superstition. Occasionally some one meets misfortune on Friday; therefore Friday is responsible. Very rarely a powerful shock or accident occurring during pregnancy is followed by the appearance of a mark on the child at birth; such a coincidence is promptly regarded as a case of cause and effect. When an expected marking doesn't appear—which is the case at very many births—the maternal-impression theory receives no discredit thereby, but possibly some pious reflection on the efficacy of prayer may be elicited instead.

Surely at this late day the maternal-impression superstition should be relegated to the medical lumber-room. When it is remembered that there is practically no more anatomic or physiologic connection between the nervous systems of the mother and her unborn child than there is between the nervous systems of the setting hen and her unhatched chicks, how can the belief in the transmis-

sion of nervous influences so powerful and so selective as to produce specific localized structural lesions, be entertained. Such an unscientific theory may be good christian science or good sewing-circle-science, but surely it is too absurd a notion to merit the credence of intelligent medical men

The grief of the mother of an imperfect child is usually great enough without adding to her distress by laying the blame for the unfortunate occurrence on her. On the contrary, physicians had far better try to relieve the sacred period of motherhood of the cruel, absurd belief, that the mother can, by any possible means, "mark" her unborn child. E. T. Shelly.

Marriages.

Aug. D. Ferguson, M.D., to Miss Elma Gaulding, both of Frost, Texas, February 25.

Clinton B. Herrick, M.D., Troy, N. Y., to Miss Mary M. Slavin of Cohoes, N. Y., at Jersey City, N. J., March 19.

Abbie M. Winegar, M.D., Battle Creek, Mich., to Mr. W. Ray Simpson of Helena, Cal., at San Francisco, March 8.

Lieutenant Henry S. Kiersted, assistant surgeon, U. S. Army, to Miss Edith McBean of San Francisco, March 28.

Deaths.

John Wallace Collins, M.D. University of Louisiana, New Orleans, 1860, throughout the Civil War a surgeon in the Confederate service, professor of gynecology and abdominal surgery Denver Medical College from 1886 to 1895 and emeritus professor since 1895, president of the Colorado State Medical Society 1888-1889, physician and chief surgeon at the Colorado State Penitentiary, Canon City, died at the home of his brother, near Pueblo, March 20, aged 67.

Jonathan L. Cilley, M.D. Miami Medical College, Cincinnati, 1866, for 19 years demonstrator of anatomy in the Ohio Medical College, considered one of the greatest anatomy teachers in America; a surgeon during the Civil War in both Army and Navy, died March 18, in the Post-Graduate Hospital, New York City, from complications following an operation for Bright's disease, from which he had suffered for eighteen months, aged 65.

Cyrus E. Baker, M.D. College of Physicians and Surgeons, New York, 1862, who served as acting assistant surgeon in the volunteer forces until 1863, when he was invalided on account of sunstroke and malaria, and who thereafter practiced in Claremont, N. H., died at his home in that place, March 23, after many years of ill-health, aged 67.

J. Augustus Carncross, M.D. Jefferson Medical College, Philadelphia, 1876, assistant physician at the Friends' Hospital for the Insane, Frankford, Pa., a member of the Philadelphia County Medical Society, and a well-known authority on nervous and mental disease, died at the hospital, March 19, after a short illness from heart disease, aged 58.

Frederic L. Marcotte, M.D. Chicago Medical College, 1877, of Concordia, Kan., formerly surgeon of Missouri Pacific and Burlington and Missouri River railways; formerly president Republic County Medical Society, died at Leavenworth, Kan., where he had been taken for treatment, March 18.

William Eastman, M.D. Rush Medical College, Chicago, 1871, a member of the American Medical Association, and one of the most prominent practitioners of southwest Wisconsin, died at his rooms in Mineral Point, Wis., March 15, from paralysis, after an illness of a few hours, aged 70.

Charles B. Ferrell, M.D. Bellevue Hospital Medical College, New York, 1873, member of the Franklin County Medical Society, and some-time physician at the state penitentiary, died at his home in Columbus, March 23, from meningitis, after an illness of two weeks, aged 63.

Charles Howell, M.D. University of Michigan, Ann Arbor, 1861, died at his home in Ann Arbor, Mich., March 20, after a long illness, from paralysis, aged 73. He served throughout the Civil War as a surgeon on the Union side.

Herbert H. McAuley, M.D. Kentucky School of Medicine, 1889, of Chicago, organizer of the Chicago Hospital Corps in the Boer war, died at St. Joseph's Hospital, Joliet, after an operation for appendicitis, March 24, aged 32.

William A. Howell, M.D. University of the Victoria College, Cobourg, Ont., 1860, died at his home in Jarvis, Ont., March 23, from paralysis following spinal disease due to a fall from his horse in 1874, aged 66.

Spencer Morris, M.D. Cincinnati, 1846, for many years a popular quiz-class teacher of Philadelphia, died at his home in Mount Morris, Pa., after an illness of four years, from paralysis, aged 82.

Charles W. Dulin, M.D. College of Physicians and Surgeons, Chicago, 1895, of Kansas City, Mo , died at his home in Nevada, Mo., March 23, from typhoid fever, after an illness of two months, aged 30.

Norton Strong, M.D. Harvard Medical School, Boston, major and surgeon U. S. Army (retired), who was stricken with paralysis five years ago, died at his home in Baltimore, March 23, aged 51.

James Shackelford, M.D. Jefferson Medical College, Philadelphia, 1861, formerly a state senator, died at his residence in Maysville, Ky., March 25, after an invalidism of several years.

Hans M. Martin, M.D. Rush Medical College, Chicago, 1897, of Newark, Ill., died at St. Charles' Hospital, Aurora, Ill., March 17, from dropsy, after an illness of several weeks, aged 34.

Thomas T. Oliver, M.D. Medical Department of Victoria College, Toronto, 1853, died at his residence in Chicago, March 26, from pneumonia, after an illness of one month, aged 73

H. Turner Bass, M.D. University of Pennsylvania, Philadelphia, 1874, was shot by Dr. Julian M. Baker, March 16, and died on the following day at his home in Tarboro, N. C.

Henry Allan Noyes, M.D. Hahnemann Medical College, Chicago, 1891, of Pittsfield, Mass., died at Asheville, N. C., March 24, from tuberculosis, after an illness of a year.

James C. Burlington, M.D. Indiana Eclectic Medical College, Indianapolis, 1886, died at his home in Attica, Ind., from pneumonia, March 15, after an illness of ten days, aged 65.

Ross C. Kirkpatrick, M.D. Starling Medical College, Columbus, 1870, died at his office in Los Angeles, Cal., March 13, from angina pectoris, after a short illness, aged 60.

Roscoe M. Parsons, M.D. Chicago Homeopathic College, 1882, died at his office in Traer, Iowa, March 21, from an overdose of chloroform, taken to induce sleep, aged 55.

John M. Douds, M.D. Homeopathic Hospital College, Cleveland, 1881, died at his home in Beaver Falls, Pa., March 17, after an illness of several months, aged 60.

Frank Merritt, M.D. Detroit Medical College, 1877, twice mayor of Charlotte, Mich., died at his home in that place March 16, after an illness of three weeks.

John H. Fisher, M.D. Eclectic Medical Institute, Cincinnati, 1852, died at his home in Augusta, Mich., March 23, from pneumonia, after a short illness, aged 69.

Benjamin Miller Van Sickle, M.D. Bellevue Hospital Medical College, of New York, died at the home of his mother in Newark, N. J , March 15, aged 46.

Harvey L. James, M.D. University of Buffalo, N. Y., 1881, died at his home in Shelby, N. Y., March 14, from consumption, after a long illness, aged 46.

John Steifel, M.D. Homeopathic Medical College of Missouri, St. Louis, 1878, died at the home of his daughter in Bucyrus, Ohio, March 14, aged 78.

Charles Wesley Roberts, M.D. Hahnemann Medical College, Philadelphia, 1889, died in Scranton, March 20, from heart disease, aged 55.

John Miller, M.D. Heidelberg and Berlin, Germany, died at his home in Buffalo, N. Y, March 18, from gastric ulcer, aged 79.

Walter H. Vincent, M.D. New York University, 1884, died at his home in Orwell, Vt., March 6, after an illness of one week.

Robert Safford Newton, M.D. New York University, 1876, an alienist of New York City, died at his home, March 25, aged 45.

Charles F. Parker, M.D. University of Vermont, Burlington, 1883, died at his home in Boston, March 24, after a long illness.

J. P. Shacklett, M.D. Louisville Medical College, 1880, died at his home in Ekron, Ky., March 22, after a prolonged illness.

Albert R. Erskine, M.D. University of Pennsylvania, Philadelphia, 1851, died at his home in Huntsville, Ala., March 24.

Augustus C. E. Hertel, M.D. Cooper Medical College, San Francisco, 1859, died at his home in San Jose, Cal., March 14.

J. C. Archer, M.D. Ensworth Medical College, St. Joseph, Mo., 1898, died recently at his home in South St. Joseph, Mo.

Frederick Alexander Hesler, M.D., surgeon-lieutenant U. S. Navy, died at sea, March 11, from heart disease.

Warren O. Blaisdell, M.D. 1878, died at his home in Macomb, Ill., from rheumatism of the heart, March 18.

Julius C. Fox, M.D., 1878, died at his home in Keyesport, Ill., March 12, aged 65.

Book Notice.

BIOLOGICAL LABORATORY METHODS. By P. H. Mell, Ph.D., Director of Alabama Experiment Station. Cloth. Pp. 321. Price, $1.60. New York: The Macmillan Co. 1902.

This little book, while not strictly medical, is one that can be of use to the physician who utilizes the microscope. There are many uses for the microscope, moreover, that are not strictly medical which would be a profitable recreation at least for the physician who has time on his hands. The special advantage of the book is the fulness of its illustrations and descriptions of the biologic methods. It may be a little deficient in purely medical details such as special tissue stains, etc., but on the whole it is very complete.

Miscellany.

Skill in the combination of drugs, not only to increase the physiologic action of each, but to make the medicine pleasant of administration, is greatly to be desired and has made the reputation of many a man. But to attempt to prescribe for every symptom of a disease by throwing unskillfully together eight or ten drugs, as is too often done, is unscientific, dangerous and is that abomination of abominations—polypharmacy. —H. R. Purdy.

For the Removal of Tattooing.—Those who have been tattooed and who regret it may succeed in ridding themselves of these marks by the following process: Pour on the tattooed portion a concentrated solution of tannin, then by means of a needle analogous to that of the tattooer, prick the surface and then rub hard with a nitrate of silver pencil. There is formed a slough which falls at the end of fourteen or eighteen days, and the operation leaves only a slight scar, which at the end of two months is invisible.—"Cosmos."

No Patent Medicines at St. Louis Fair.—J. A. Ockerson, chief of the liberal arts department of the St. Louis exposition, says: "Articles that are in any way dangerous or offensive; also patent medicines, nostrums and empirical preparations whose ingredients are concealed, will not be admitted to the exposition. The director of exhibits, with the approval of the president, has the authority to order the removal of any article he may consider dangerous, detrimental to or incompatible with the object or decorum of the exposition or the comfort and safety of the public."—"Practical Druggist."

Overfeeding and Cancer.—Oldfield urges in the "British Medical Journal" that the overfeeding of animals and the retention in their tissues of the decomposition products make the eating of such animals as food productive of an unstable cell equilibrium which foreruns the cancer incidence, and that the same thing applies to vegetables, though in a lesser degree. During his late tour through India he found cancer practically absent from all areas where vegetation was sparse and where the animals used for food had lived a hardy existence, but in those regions marked by ranker vegetation and where the animals were more highly foddered it was more prevalent.

The Cocain Evil.—The law of Illinois specifically prohibits the sale of any article, open or proprietary, containing cocain, except on the prescription of a physician. . . . The law is certainly one of the most righteous ever enacted by a legislative body. The curse of the cocain habit to-day afflicts thousands of homes, from the palaces of the rich to the hovels of the poor. It is doubtful if the evils of alcoholism are more extensive or more destructive in their effects on society than the insidious and deadly ravages of cocain. . . . What the statute prohibits in Illinois the conscience of every druggist in America should as resolutely prohibit, and any thought of profit arising from complicity in the traffic should be as foreign as complicity in any other dastardly crime against his patrons or society in general.—"Western Druggist."

Adulteration.—Nearly every drug in the Pharmacopeia is adulterated, and, as such, fails to give the desired action. So great has this evil become that we often confess to one another that we prescribe less and less, and confine ourselves to a few fundamental drugs, remedies which we think we obtain from reliable sources and give in cases of necessity, leaving our patients to take their favorite compounds of tonics and appetizers on their own responsibility. . . . If drugs could be treated sacredly, exactly and conscientiously by the druggists, and by the public, as they are in hospitals, in experimental laboratories, and as physicians themselves treat them, the practice of medicine would be a much more satisfactory profession than it is at present.—"Medical News."

Queensland More Progressive than the United States as to the Adulteration of Foods.—While we wait in vain for our political bosses to do something for the health of the people, Queensland has perfected a system to protect her citizens from the scoundrels who seek to cheat them by the most vicious criminality in the manufacture of impure and poisonous foods. Strict laws are enforced in Queensland as to the substances that may and may not be used as ingredients, coloring matters, preservatives, etc., of beer, alcoholic liquors, mineral waters, fruit essences, foods, milk, tea, vinegar, butter, cream of tartar, etc. There are detailed laws also as to the carrying on of the businesses pertaining to the manufacture and sale of all such things, and a fine not exceeding $250 is provided for infringement of any parts of the law. Were it not for the hope that the careless and corrupt and ignorant among our people and their lawmakers will at last renounce their ways and become interested in the health and welfare of the nation, the outlook for republicanism in government would not be hopeful. —"American Medicine"

Diarrheic Form of Hyperchlorhydria.—Hyperchlorhydria is usually accompanied by constipation, but there is a variety with diarrhea, either paroxysmal or constant. Both the diarrhea and the constipation are evidently defensive reactions on the part of the intestine to the hyperacid chyme. Surmont and Lerat have been making a special study of the diarrheic form and proclaim that it is undoubtedly due to imperfect closure of the pyloric orifice, and this insufficiency is the result in turn of nervous influences, a muscular asthenia. These nervous influences are demonstrated also in the intense depression that follows the attacks, the violent abdominal pains occasionally experienced, and the secondary influence of emotions or chilling, noticed in all cases of diarrhea. Diagnosis is almost impossible without chemical investigation of the stomach contents, but differentiation is important as prognosis and treatment directly depend on it. The paroxysms of diarrhea usually occur in the middle of the night; the pain is located in the epigastrium and around the umbilicus. It subsides abruptly as the desire is felt. The subject experiences afterward great nervous depression and a nausea and distress recalling the sensations of seasickness. This condition does not subside until toward morning, and if the subject drops to sleep he awakes from time to time with a start. One of Surmont's patients was an army officer and his depression after a paroxysm was so extreme that he feared he would be compelled to leave the service, as he realized the impossibility of responding to any professional calls at such times. The condition resembles the nervous depression liable to follow the paroxysmal sialorrhea of certain tabetics or certain profuse sweats. The diarrhea may be the only apparent symptom of the hyperchlorhydria. One of the patients with the permanent form of diarrhea from this cause was a child of 11. This diarrhea always occurs very early in the morning or after breakfast and lunch. There is usually considerable pain and some nervous depression follows. Treatment is that of hyperchlorhydria in general with hydrochloric or phosphoric lemonade in cases rebellious to the usual measures.—"Echo Méd. du Nord," vii, 2.

Privileged Communications and the Physician.—At the last meeting of the New York Society of Medical Jurisprudence

Alfred L. M. Bullowa, a lawyer, read a paper entitled "The Medical Secret, or the Privilege of Physicians in Court Proceedings." He said that the present code gave every practicing physician the right to decline to answer any question or to give any testimony which would reveal any secret, condition or fact that had come to him by reason of his professional duties. This provision of law in this country is of the first importance in life insurance cases, and next in inheritance cases, where insanity on the part of the testator might be alleged. The physician is not expected to divulge professional secrets, even if he knew that his patient was deliberately perpetrating a fraud. Physicians complain that the law bears hard on them when they desire to sue for professional services, but lawyers are similarly prevented from detailing the nature of their services. In supplementary proceedings, or in bankruptcy actions, no call can be legally made on physicians for their account books if the latter contain information regarding their patients of a privileged character.

State Boards of Registration.

Texas Examination.—The next meeting of the Board of Medical Examiners (Regular) for the State of Texas will be held in Austin, April 20 to 23. For further information or application blanks, address Dr. M. M. Smith, secretary, Austin, Texas.

Indiana Examination.—A special meeting of the Indiana State Board of Medical Registration and Examination is called for April 23, when this year's graduates of the medical colleges of that state will be licensed to practice. They will receive certificates without examination if they matriculated before Jan. 1, 1901, but after Jan. 1, 1905, all graduates will be obliged to take examinations.

New Arizona Law.—The new medical practice act of Arizona, which has just passed the legislature, provides for a board of medical examiners, three regular, one homeopathic and one eclectic, appointed by the governor, meeting quarterly at Phœnix, and at such other times as it may appoint. The law provides for the issuance of license to those who are residents of Arizona, are of the age of 21 and are of good moral character, and who in addition: 1, present diploma and pass examination; or 2, present diploma and show certificate of license under the laws of 1901 or 1897; or 3, have practiced for five successive years previous to the passage of the act and pass an examination. The law provides how application shall be made, sworn to, and how certification shall be made as to character and length of practice. The fee for license is $2, and for examination $10. Those who have complied with previous laws are given until June, 1903, to comply with this law. Violation is punishable by a fine of $100 to $1,000 or imprisonment for three months to one year, or both fine and imprisonment. Other provisions of the law appear in the following portions quoted:

Sec. 5. The examination provided for in the preceding section shall be made by said board as soon after the application shall have been presented as it may be conveniently done and after notice to the applicant of the time and place thereof. The examination shall be conducted under such reasonable rules and regulations as the board may prescribe therefor, and with the design and purpose of ascertaining the fitness of the applicant for the practice of medicine in this territory. If the applicant request it, he or she shall have the privilege of being examined in the branches of the science and practice of medicine other than physiology, anatomy, pathology, chemistry, practice, surgery, obstetrics and gynecology, by the member or members of the board of the particular school of medicine specified in his or her diploma, and if the examination in such other branches be satisfactory to the member or members conducting said examination, it shall be approved by the board and to the extent thereof be deemed to be to the board's satisfaction.

Section 7. Upon proper proof to the Board of Medical Examiners of Arizona that the holder of any license issued under the provisions of this act has been guilty, since the issuance thereof, of any grossly immoral or unprofessional conduct, or of other conduct rendering him or her unfit to practice medicine in this territory, or has been convicted of any felony, said board shall, after due notice to such holder and full opportunity to him or her to defend against or refute such charges, revoke and cancel such license, and it shall thereafter be unlawful for such person to practice medicine in this territory until he or she shall again be licensed thereto under the provisions of this act.

Sec. 10. Any person shall be regarded as practicing medicine within the meaning of this act, who shall, within this territory, (a) by advertisement, or by any notice, sign or other indication, or by any statement, printed, written, or oral, in public or in private, made, done or procured by himself or herself, or any other, at his or her request for him or her, claim, announce, make known or pretend his or her ability and willingness to diagnosticate or prognosticate any human diseases, ills, deformities, defects, wounds or injuries: (b) or who shall so advertise or make known or claim his or her ability and willingness to prescribe or administer any drug, medicine, treatment, method or practice, or to perform any operation, or manipulation, or apply any apparatus or appliance for cure, amelioration, correction, reduction or modification of any human disease, ill, deformity, defect, wound or injury, for hire, fee, compensation or reward, promised, offered, expected, received or accepted, directly or indirectly; (c) or who shall within this territory diagnosticate or prognosticate any human diseases, ills, deformities, defects, wounds or injuries, for hire, fee, reward, or compensation, promised, offered, expected, received or accepted directly or indirectly; (d) or who shall within this territory prescribe or administer any drug, medicine, treatment, method or practice, or perform any operation or manipulation, or apply any apparatus or appliance for the cure, alleviation, amelioration, correction or modification of any human disease, ill, deformity, defect, wound or injury, for hire, fee, compensation, or reward, promised, offered, expected, received or accepted, directly or indirectly; (e) or who shall act as the agent of any person, firm or corporation, in the practice of medicine as hereinbefore set forth; (f) except it be in the advertisement or practice of dentistry, midwifery, or pharmacy, or in the usual business of opticians, or of vendors of dental or surgical instruments, apparatus or appliances.

Sec. 11. The provisions of this act shall not be construed to modify, or in any wise affect the provisions of the laws of this territory relating to the practice of dentistry.

Association News.

NEW ORLEANS HOTELS.

ST. CHARLES HOTEL FILLED—ANNOUNCEMENT OF HOTEL COMMITTEE.

Dr. E. D. Martin, New Orleans, Chairman of the Committee on Hotels, writes that all accommodations in the St. Charles Hotel, the headquarters, are taken for the time of the meeting. He requests that physicians who write for reservation of rooms specify what they desire, as to the time of their arrival and departure, price, baths, single or double rooms, etc. THE JOURNAL next week is the special New Orleans Number, containing an elaborate write-up of New Orleans, with many illustrations thereof. Full particulars of hotels, railroads, excursions, programs, etc., will be given.

Medical Organization.

Humboldt County (Cal.) Medical Society.

Members of the medical profession met at Eureka, March 7, and organized a county medical society, which asked affiliation with the state society.

Athens County (Ohio) Medical Society.

This society was organized at Athens, March 3, with the following officers: Dr. Charles S. McDougall, Athens, president; Dr. Edmund F. Danford, Glouster, vice-president; Dr. Ulysses P. White, Athens, secretary, and Dr. David H. Biddle, Athens, treasurer

Rowan County (Ky.) Medical Society.

The physicians of Rowan County met at Morehead, March 21, and organized a county society, after listening to an address by Dr. Joseph E. Wells, Cynthiana, councilor for that district. The constitution and by-laws prepared by the American Medical Association were adopted without change and the following officers elected: President, Dr. F. M. Carter, Farmers; secretary, Dr. Jeremiah Wilson, Morehead.

Bath County (Ky.) Medical Society.

The physicians of Bath County met at Owingsville, March 20, and organized a county society, and adopted the constitution and by-laws promulgated by the American Medical Association without change, after an address on the subject of organization by Dr. Joseph E. Wells, Cynthiana, councilor of the district. The following officers were elected: President, Dr. Henry H. Lewis, Salt Lick; secretary, Dr. J. W. Rutherford, Sharpsburg.

Fleming County (Ky.) Medical Society.

The physicians of Fleming County held a meeting at Flemingsburg, March 18, and organized a county society, and adopted the constitution and by-laws proposed by the American Medical Association, after listening to a talk on organization from Dr. Joseph E. Wells, Cynthiana, councilor of the district. Dr. Alvin M. Wallingford, Mt. Carmel, was elected president; Dr. Charles R. Garr, Flemingsburg, vice-president, and Dr. Addison S. Robertson, Flemingsburg, secretary and treasurer.

Nelson County (Ky.) Medical Society.

The physicians of Nelson County, met at Bardstown, March 21, and organized a county society, adopting the constitution and by-laws prepared by the American Medical Association without change. The following officers were elected: President, Dr. J. Edward Smith, Bradstown; vice-president, Dr. William J. Heiser, New Haven; secretary, Dr. Hugh D. Rodman; treasurer, Dr. H. E. McKay, both of Bardstown, and delegate to the state association, Dr. Aloysius G. Blincoe, Bardstown.

Nichols County (Ky.) Medical Society.

The physicians of Nicholas County met at Carlisle, March 17, and organized a county society, after listening to an address by Dr. Joseph E. Wells, Cynthiana, councilor of the district, and adopted the county constitution and by-laws of the American Medical Association without change. The following officers were elected: President, Dr. G. W. Grimes, Carlisle; vice-president, Dr. H. Yancey, Carlisle; secretary, Dr. George B. Spencer, Carlisle; treasurer, Dr. Samuel R. Fisher, Headquarters; delegate to the state association, Dr. B. F. Reynolds, Carlisle; censors, Drs. N. H. McNew, Harry Munger and Malcolm Dills.

Societies.

COMING MEETINGS.

AMERICAN MEDICAL ASSOCIATION, FIFTY-FOURTH ANNUAL MEETING, NEW ORLEANS, MAY 5-8.

Florida Medical Association, St. Augustine, April 8.
Western Ophthalmological and Oto-Laryngological Association, Indianapolis, April 9-11.
Tennessee State Medical Society, Nashville, April 14-16.
Medical Association of Georgia, Columbus, April 15.
South Carolina Medical Association, Sumter, April 15-16.
Iowa State Medical Society, Sioux City, April 15-17.
Mississippi State Medical Association, Greenville, April 15-17.
Medical Association of the State of Alabama, Talladega, April 21.
Medical Society of the State of California, Santa Barbara, April 21.
Medical Association of the State of Missouri, Excelsior Springs, April 21-23.
Kentucky State Medical Society, Louisville, April 22-24, 1903.
Texas State Medical Association, San Antonio, April 28.
Louisiana State Medical Society, New Orleans, April 28-30.
Medical and Chirurgical Faculty of Maryland, Baltimore, April 28-30.
Nebraska State Medical Society, Lincoln, April 28-30.
Illinois State Medical Society, Chicago, April 29-May 2.
Arkansas Medical Society, Jonesboro, April 30-May 2.
Association of American Medical Colleges, New Orleans, May 4.
American Proctologic Society, New Orleans, May 5.
Kansas Medical Society, Concordia, May 6-9.
American Academy of Medicine, Washington, D. C., May 11-12.
American Association of Genito-Urinary Surgeons, Washington, D. C., May 12-14.
American Surgical Association, Washington, D. C., May 12-14.
American Therapeutic Society, Washington, D. C., May 11-13.
American Medico-Psychological Association, Washington, D. C., May 12-15.
American Ophthalmological Association, Washington, D. C., May 13-14.
American Orthopedic Association, Washington, D. C., May 12-14.
American Pediatric Society, Washington, D. C., May 12-14.
Association of American Physicians, Washington, D. C., May 12-14.
Oklahoma Territorial Medical Association, Guthrie, May 12.

Florida Medical Association.—The thirtieth annual session will be held in St. Augustine, April 8, 9 and 10.

North Texas Medical Association.—This association has been incorporated at Sherman by Drs. Joseph M. Fort, Paris; J. T. Wilson, Sherman, and Bacon Saunders, Fort Worth.

Medical Society of the State of North Carolina.—The fiftieth annual meeting will be held at Hot Springs, June 2, 3 and 4. An especially attractive program is being prepared to honor the semi-centenary of the society.

San Bernardino (Cal.) Medical Society.—This society held its annual meeting and banquet, March 11. Dr. C. Van Zwalenburg, Riverside, was elected president, and Dr. Joseph A. Champion, Colton, secretary and treasurer.

Wichita (Kan.) Academy of Medicine.—About fifty physicians of Wichita met, March 16, adopted a constitution and organized an academy of medicine, with the following officers: Dr. James E. Oldham, president, and Dr. J. M. Jacobs, secretary.

Kansas City (Mo.) Medical Library Association.—The Jackson County Medical Society and the Kansas City Academy of Medicine have joined in incorporation of the Kansas City Medical Library Association to establish a library for the medical profession of Kansas City and its vicinity. The collection now numbers about eight hundred volumes.

San Joaquin Valley (Cal.) Medical Association.—At the fifteenth semi-annual meeting held in Fresno, March 10, the following officers were elected: Dr. Joseph D. Davidson, Fresno, president; Drs. Walter E. Lilley, Merced, Nathaniel P. Duncan, Hanford, and M. L. Pettit, Visalia, vice-presidents; Dr. John R. Walker, Fresno, secretary, and Dr. Thomas M. Hayden, Fresno, treasurer.

Chicago Medical Society.—At its meeting, March 25, the society elected the following fifteen councilors-at-large: Drs. Charles S. Bacon, Arthur D. Bevan, Frank Billings, W. S Christopher, N. S. Davis, Joseph B. DeLee, Arthur R. Edwards, Adolph Gehrmann, David W. Graham, Malcolm L. Harris, Fernand Henrotin, James B. Herrick, Louis L. McArthur, Walter Van Hook, and George W. Webster. Fifteen other councilors will be elected by the branches and affiliated societies. The councilors constitute the governing body and will elect the president and other officers and trustees at the June meeting.

Aberdeen District (S. D.) Medical Society.—This society, which comprises twelve counties in the northeast corner of the state, held its annual meeting at Aberdeen, March 17, at which the following officers were elected: Dr. Charles B. Mallery, Aberdeen, president; Dr. Lynn A. Pickering, Warner, vice-president; Dr. Henry J. Rock, Aberdeen, secretary and treasurer; Dr. Robert Hill, Ipswich, censor for three years, and Dr. Henry J. Rock, Aberdeen, delegate to the next meeting of the state association. After the routine business and reading of papers, a banquet was served in honor of Dr. H. E. McNutt, Aberdeen, at which he was presented with a fine fur-lined overcoat, as a slight testimonial of appreciation of his successful efforts in improving the standard of the profession in the state by the passage of the new medical bill requiring examination.

BUFFALO ACADEMY OF MEDICINE.

Meeting of the Section on Pathology, held March 17, 1903.

Dr. Irving P. Lyon in the Chair.

The Cardiac and Vascular Complications of Typhoid Fever.

DR. W. S. THAYER of the Johns Hopkins Hospital, Baltimore, read this paper.

Among the cardiac complications of typhoid fever we first meet acute endocarditis. The bacillus of typhoid fever has been found in this lesion. Pericarditis is a rare complication, while myocarditis is met extensively. Acute myocarditis complicating typhoid gives its clinical symptoms. Among the vascular complications we find acute endarteritis and arterial thrombosis. Gangrene of extremities due to this change has occurred.

As an exhibit under the microscope, Dr. Thayer presented a section of acute coronary endarteritis. The venous changes are better known than the arterial, e. g., venous thrombosis, which is secondary to a phlebitis. The typhoid bacillus has been found in the wall of the vessel.

In the reports of the Johns Hopkins Hospital from May, 1899, to Jan. 1, 1901, there were 1,357 cases of typhoid fever. Of these 122 cases were fatal, or about 9 per cent. In 156 cases the pulse was over 140. In only 2 per cent. of cases was the pulse under 50, in these latter cases there was no death; all convalesced. In 215 cases there were cardiac murmurs on admission; the murmurs were mostly soft systolic. A peculiarity about these murmurs was that they were only noted on first examination, not afterwards. The excitement incidental to admission, etc., can account for this. Diastolic murmurs were not met with unless the patients have given a history of having same previously. In all there were two cases of pericarditis and two cases of endocarditis. These cases were reported and were interesting. The two cases of acute endocarditis were unsuspected during life were, therefore, only found at necropsy.

In regard to vascular changes in these cases reported, there were 38 cases of venous thrombosis, of which 5 were fatal.

Of these 38 cases, 36 were of the lower extremities, and mostly the left side. Thrombosis of the left iliac vein was comparatively frequent in connection with lower extremities. In all these cases of venous thrombosis this complication occurred toward the end of the fever. The typhoid thrombosis was found in one thrombus. Of the 122 fatal cases, autopsies were had in 87 cases.

Dr. Thayer urges a more general examination of the arterial lesions to see frequency of involvement. In several cases the aorta and mitral valve were involved. One hundred and twenty-six cases were accurately examined and blood pressure noted in the recumbent posture in bed. The ages varied from 8 to 69, the majority being under 30. Of these 126 cases 8 developed cardiac complications after admission. In 52.3 per cent. of the cases the radial was palpable. In 46 per cent. of the cases the radial was not palpable. The few remaining were not reported. In 110 cases the blood pressure was above normal.

Dr. Thayer did not make any general conclusions, wishing, rather, to excite the interest and the more minute examination of these complications in typhoid fever.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Injections of Yolk of Egg in Tuberculosis.

Dr. T. Boyle, in "Amer. Jour. Med. Sciences," recommends the use of the yolk of the egg, combined with equal parts of a normal salt solution, administered hypodermically. One ounce may be introduced beneath the skin without producing local irritation. He claims that the lecithin, normally present in the yolk of the egg, does not undergo the molecular change which takes place when it passes through the digestive tract. The mode of introduction hypodermically is recommended only when the digestive processes are not normal. The lecithin of the yolk is more stable than that put on the market.

Ipecac in Pneumonia.

The following method has been recommended by Perreau, in "St. Louis Clinic," in the treatment of pneumonia:

℞.	Pulv. ipecac.	gr. xv	1
	Mucil. acaciæ	ʒiii	90

M. Sig.: One teaspoonful every hour for eight doses.

Care should be observed to avoid vomiting and diarrhea by lengthening the intervals between the doses. The author states that by this method of treatment the lung is depleted and counteracts microbic infection. He reports splendid results, especially when the treatment has been begun early.

Acute Laryngitis.

The following combinations are recommended by "Merck's Archives" in the treatment of acute laryngitis:

℞.	Potass. cit.	3iv	15
	Dionin	gr. vi	35
	Tinct. aconite	m. xxiv	1 60
	Spts. etheris nitrosi		
	Syr. tolutani, āā	3vi	24
	Aquæ q. s. ad	ʒiii	90

M. Sig.: One teaspoonful in water every two hours to relieve the cough, fever and hoarseness; or:

℞.	Menthol	3iss	6
	Olei pini sylvestris		
	Olei eucalypti		
	Tinct. benzoini		
	Tinct. tolutani, āā	3i	4

M. Sig.: To be used as an inhalation from a steam kettle several times daily.

Ulcer of Stomach.

Westphalen, in an abstract in "Med. Press," recommends in the treatment of round ulcer, that in the beginning nothing be given by the mouth, except a little cold tea or Vichy water or small pieces of ice. Nutrient enema may be used during this period if necessary. This period of starvation by the mouth may continue over a period of from six to sixteen days. Then the author gives four glasses of milk daily, increasing the quantity half a glass each day. After another period of ten days he adds soups and more solid food. He advises the continuance of fresh milk or whey, with cream, as they reduce the hyperacidity of the stomach, the milk keeping the motor function of the stomach at a minimum. He also recommends bismuth in heaping teaspoonful doses, in a glass of water before breakfast in the morning. The diet should be regulated for a year. The patient should be kept in bed for three weeks at the beginning of the treatment.

Syphilis.

Horwitz, in the Amer. Text-Book of Ther., recommends the following in the treatment of the initial chancre:

℞.	Unguenti hydrargyri nitratis	gr. xx	1 30
	Unguenti iodoformi		
	Balsami peruvianæ		
	Unguenti belladonnæ		
	Unguenti zinci oxidi, āā	3ii	8

M. Sig.: Apply locally. The patient should be instructed not to allow the salve to remain too long in contact with the parts; otherwise it will become rancid and cause greater injury than benefit.

The following ointment is also recommended:

℞.	Unguenti hydrarg nit.	3ss	2
	Unguenti petrolati	ʒss	15

M. Sig.: Apply locally.

Another excellent ointment of service in hastening cicatrization is composed as follows:

℞.	Unguenti hydrargyri oxidi rubri	gr. viiss	50
	Unguenti petrolati	ʒss	15

M. Sig.: Apply locally. In the local treatment of the skin eruption the following is recommended applied to the sores after removing the crusts by the application of hot water to soften them:

℞.	Ung. hydrarg. nit.	gr. xv	1
	Balsami peruv.	3i	4
	Ung. belladonnæ	3ii	8
	Ung. iodoformi q. s. ad	ʒi	30

M. Sig.: As a local application.

The mucous patches may be easily controlled by instructing the patient to avoid all highly-seasoned foods, stimulants and such articles of diet as are liable to irritate the sores. Tobacco should be discontinued until the mouth is well. If the patches are superficial and not too numerous they should be touched with the following solution:

℞.	Argenti nitratis	gr. xxx	2
	Aquæ destil	ʒi	30

M. Sig.: Apply once daily to the patches.

The following astringent mouth wash should be used:

℞.	Potassii chloratis	3iii	12
	Acidi tannici	gr. xx	1 30
	Olei gaultheriæ	gtt. vii	35
	Glycerini	3ii	8
	Aquæ q. s. ad	ʒvi	180

M. Sig.: As a mouth wash two or three times a day.

And for the alopecia, to stimulate the new growth of hair, the author recommends the following:

℞.	Hydrarg. chloridi corros.	gr. vi	35
	Tinct. cantharidis		
	Tinct. capsici, āā	3iii	12
	Spts. ammon. arom.	3vi	24
	Spts. rosmarini	ʒvi	180
	Alcoholis q. s. ad	ʒxii	360

M. Sig: Apply locally to the scalp with a sponge moistened in the solution and use thorough friction.

Rickets.

I. A. Abt, in "Archiv. of Ped.," recommends, in treatment of rickets, that the patient be kept out of doors in order to receive an abundance of fresh air and sunshine. During the first stages of the disease children should not occupy, for too long a time,

the same position in bed on account of the softness of the bones. Spinal curvatures may also occur in infants who are held or carried in the sitting posture. They should not be allowed to stand or walk too soon for the same reason.

As to the diet, it should be digested without giving rise to fermentation or putrefaction. The food should be fresh and should contain as much fat as the child can take care of; fruit juices, beef juice and the animal broths should constitute part of the diet.

The most useful medicinal preparation is cod liver oil, given pure in doses of one-half teaspoonful three times a day. It is not so well tolerated in the summer time and had better be omitted during the summer months. Phosphorus is also recommended, and by some authors it is classified as a specific in this disease. It is best prescribed in the form of Thompson's oil, every minim of which contains 1/100 of a grain of phosphorus. The usual dose is one-half a minim or 2/200 of a grain of phosphorus.

Baths are of decided therapeutic value. Salt baths are indicated in those children who perspire profusely.

Medicolegal.

Physician Can Not Enjoin Removal from Reformatory.—The case of Marshall vs. the Board of Managers and Superintendent of the Illinois State Reformatory was brought by the former to restrain the latter parties from removing him from the office of physician of said reformatory. But the Supreme Court of Illinois thinks it clear that the trial court did not err in dissolving the temporary injunction granted and dismissing the case for want of equity, as it says that it is well settled that the title to a public office and the right to exercise its functions can not be determined by a court of chancery unless express authority so to do is conferred on the court by statute, the remedy being in a court of law. This reformatory, it holds, is a penal institution, and the position therein of physician is an office, and a court of chancery has no greater power to determine the title to such office than the title to any other public office.

Unlawfully Exposing People to a Contagious Disease.—In Nebraska all public offenses are statutory, and no person can be punished for any act or omission not made penal by the plain import of the written law. In view of this, in the case of State vs. De Wolfe, where the latter was charged with having unlawfully exposed the citizens of a village to a contagious disease by negligently keeping an infected person in a public place, the district court held that no prosecution could be maintained for the acts complained of, the code failing to specify them. But the Supreme Court of Nebraska holds that the trial court erred in dismissing the action. It says that there is as much reason now as there ever was to repress conduct calculated to injure the health of the people. Without a clear expression of purpose so to do, it can not believe that it was the intention of the legislature to so limit the meaning of the word "nuisance" as to make conduct blameless which has always been considered inherently wrong and deserving of punishment. And while there are in the state no common-law crimes, the definition of an act which is forbidden by the statute, but not defined by it, may be ascertained by reference to the common law. So a statute declaring all common nuisances to be criminal is to be construed as prohibiting every act which was by the common law indictable as a nuisance.

Current Medical Literature.

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

Philadelphia Medical Journal.

March 21.

1 *A Review of the Recent Literature on the Intercommunicability of Human and Bovine Tuberculosis. John M. Swan.
2 *Cryoscopy. D. S. Grim.
3 Trunecek's Serum and Its Value in Disturbed Cerebral Functions Caused by Circulatory Changes, with Report of Twelve Cases. Alfred Gordon.
4 *The Operative Treatment of Goiter. Ingersoll Olmsted.
5 *Psychopathic Epidemics. (To be continued.) John B. Huber.
6 A Case of Diabetes Mellitus in a Young Child. James H. Lloyd.

1. **Bovine and Human Tuberculosis.**—Swan reviews the literature and concludes that the two disorders are intercommunicable, and closes his article by summarizing Koch's paper and his arguments against this view. He thinks it is a mistake to adopt extreme opinions concerning the organism causing the disease, but holds that while there are differences, they belong to the same parent stock and are modified by their environment.

2. **Cryoscopy.**—The methods of cryoscopy are described by Grim, who also gives a review of the theories as regard to it as summarized in the following conclusions:

1. Cryoscopy can not replace, but only supplement, the older qualitative tests and microscopical examination of urines.
2. It is probably the most delicate test we possess in detecting and estimating the effect of therapeutic measures directed toward cardiac and kidney lesions.
3. It permits of reasonable accuracy in diagnosing renal insufficiency and the type of renal lesion present, though the examinations should be prolonged over a number of days; our conclusions coinciding with Lindemann's.
4. Uremia can not be diagnosed from the examination of the urine alone.
5. Cryoscopy of the urine from each kidney, obtained by ureteral catheterization, and especially when supplemented by the phloridzin and methylene blue tests, becomes a very delicate and reliable test in determining a unilateral kidney lesion and the degree of insufficiency of the affected kidney.

Because of an insufficient number of cryoscopic examinations of the blood, we can not criticize the "interchange" theory of Koranyi.

4. **Operative Treatment of Goiter.**—Kocher's methods and results are described by Olmsted. He mentions, in conclusion, that he has operated on twelve patients during the last year, all cases of simple goiter, and one of exophthalmic goiter, apparently with good results in all, though he does not give details, reporting briefly only two. The average time of residence in the hospital for treatment was seven days. The important points in operation are absolute asepsis, ligation of all the bleeding vessels, avoiding the wounding of the gland proper, and the preservation of the recurrent laryngeal nerve.

5. **Psychopathic Epidemics.**—In this first installment of his article, Huber describes certain delusions which are frequent and are still flourishing, such as Eddyism, mesmerism, the Sanford and Simpson delusions and the Dowieism craze.

7 The Development and Ultimate Result of Medical Science. Andrew F. Currier.
8 *The Treatment of Felon. Edward Wallace Lee.
9 *Report of a Case of Epidemic Parotiditis, with Fatal Termination. W. J. S. Stewart.
10 *A Study of Tuberculous Infection—Special Susceptibility of Childhood—Causes and Methods of Infection—Factors of Development of the Disease. F. M. Pottenger.
11 *The Intravenous Injection of Formaldehyd. William L. Baner.
12 *The Hemorrhagic Diathesis as a Factor in the Production of Hemorrhage Following Removal of Tonsils and Adenoids. Frank H. Washburn.
13 The Treatment of Infantile Convulsions. (Concluded.) Adolph Goldhammer, O. C. Tarbox, and Edmund N. Huff.

8. **Felon.**—According to Lee, felon is a more serious matter than is usually supposed, and is very commonly maltreated. The method he suggests would be to give a general anesthetic with the patient in the recumbent position, with thorough asepsis, elevate the hand and arm to relieve congestion before the Esmarch bandage is applied, using slight digital pressure over the brachial artery, which will thoroughly bleach the parts before the bandage is put on. This, he says, is necessary to control the slight hemorrhage that would otherwise embarrass the operation. The hand is then placed on an aseptic towel, over a hard substance, and an incision made from a few lines back of the inflamed area to the tip of the finger, down to the bone, if necessary. The extent of the disease can be clearly seen as hemorrhage is repressed and all pus and débris should be cleaned out with peroxid of hydrogen, afterward washing the wound and cavity with a 1 per 1000 solution of bichlorid of mercury. All diseased tissue, integument, cellular tissue, tendon, periosteum and bone, etc., should be removed, not leaving a vestige; again washing the wound out with peroxid and bichlorid. The whole cavity should then

be swabbed with pure carbolic acid, immediately followed by a washing with alcohol, which will prevent over-action of the carbolic acid, and again washed with a 1 to 1000 bichlorid of mercury solution. The wound can be then closed and held in position with a snug compress, over which a dry gauze bandage is applied and over this a rubber tissue, and over all, including the whole hand, cotton gauze and a bandage, the arm and hand being placed on a splint and elevated. In four or five days the dressing can be removed. If the work has been well done the wound will be found closed, free from discharge and on rapid road to recovery. The same dressing should be reapplied, and four days more will show all the parts united. The wound now only needs a protective dressing until new epidermis and skin have formed. He thinks the results justify the pains taken in this method of treatment.

9. Fatal Parotiditis.—Stewart reports a case of a sailor who apparently died from heart failure, due to the excessive strain to which that organ has been subjected from embarrassed respiration for some hours before death. The obstruction was due to swelling from the parotiditis, but the death was unanticipated, as it did not seem so serious. He has not found any such case on record, nor ever read of a death from asphyxiation in this disease. It was not the immediate cause of death in this case.

10. Tuberculosis of Childhood.—Pottenger has studied tuberculous gland infection, etc., in children, and finds, from the facts and study of the literature which he reviews, that tuberculosis is common in childhood, causing about 25 per cent. of the deaths occurring during the last quarter of the first year, and quite a large proportion of those during the second and third years. Nearly all cases of tuberculosis show involvement of the lymph glands; and, if the fact that the process is furthest advanced is an indication, they are in a large percentage of cases to be considered the primary foci. Nearly all children show enlarged glands during the period of infancy and early childhood, of which investigation seems to show from 60 to 70 per cent. to be tuberculous, and, of those chronically enlarged, even a larger per cent. are so affected. A large proportion of those who have enlarged glands during childhood develop tuberculosis in later life; and it is probable that the gland was frequently the primary focus whence came the spread of infection. Why the bacilli do not cause a general tuberculosis in these children with lowered vitality has not been explained. It may be that they are less virulent, as has been shown by experiments, and it is possible that they meet with such opposition in these structures that they are unable to make further headway. He suggests that it will be well to collect all statistics to see if children exposed to tuberculous infection from parents and others do not have a more virulent form than those who receive their infection from less virulent sources. He thinks that the reason of the prevalence can be explained by the general mismanagement of children, their habits of putting everything into the mouth, creeping on the floor with exposure to dust, etc. Pottenger believes that many cases of tuberculosis in the adult are due to primary foci acquired in childhood. We are too apt, he says, to consider the infection as originating at the time it makes its marked appearance, though he would not say that adults can not acquire it. It is at the adolescent period that these foci are most liable to become active, during the special strain of sexual changes, social functions, studies, etc. It is the second period of life when the vitality is low and, as in early childhood, it is marked by an increased number of tuberculosis cases. From the total of his investigations he deduces the following general conclusions:

1. Tuberculous infection is very common in early childhood.
2. A large proportion of those patients who, although infected, do not show acute symptoms during childhood, develop active tuberculosis in later life.
3. In seeking the cause of this frequent infection, aside from the habits of the child and the carelessness of the parent bringing it in frequent contact with the bacillus, all those things which lower vitality at this time must be considered; and, I would call special attention to the fact that there is a connection which seems more than coincidence in the time that tuberculous infection takes place and the time that the child is most apt to suffer from catarrhal conditions of the stomach and bowels.
4. More attention should be given to the care and feeding of children, so that their systems may be resistant to infection.
5. All tuberculous children, whether they have lesions in the glands, bones, lungs, or any other part of the body, should be treated for their disease.

11. Formaldehyd Intravenous Injections.—Baner notices Barrow's experiences and the experimental results of Fortescue-Brickdale and others, and says from the available facts it seems improbable that formaldehyd used intravenously has a specific value in sepsis. One thing suggests itself to him, however, that we are too apt to be forgetful of the intravenous route in cases of intense toxemia, and rely too much on hypodermoclysis and the rectal enema for that dilution of the toxins which gives the poisoned tissues a breathing spell, as it were, and enables them to keep up the battle. The intravenous injection of antiseptics probably does not kill the bacteria in the blood in septic cases, but does dilute the toxins. A normal saline solution by the same route will do this equally well, and there is less danger probably of injuring the blood.

12. Hemorrhagic Diathesis.—Washburn reports a case of severe hemorrhage following removal of tonsils, with subsequent recovery, and discusses the possibilities of hemorrhagic diathesis in these cases.

Medical News, New York.

March 21.

14 *Some Types of Retinitis and Chorioretinitis. Alexander Duane.
15 *The Indications for Operative Interference in Intracranial Tension. Frederic S. Dennis.
16 *A Preliminary Report of the Venous Hum in Relation to the State of the Blood. C. N. B. Camac.
17 Some Physiological Observations on a Crustacean Heart. (To be continued.) George V. N. Dearborn.
18 *Pneumonia. An Infectious Disease. J. O. Cobb.
19 *Observations on American Climates and Localities in the Treatment of Pulmonary Tuberculosis. James K. Crook.

14. Retinitis and Chorioretinitis.—The types here noted by Duane are focal exudative chorioretinitis, occurring with acute onset, rapid course and a generally favorable prognosis, usually in young people and often without apparent cause, marked by the presence of single circumscribed exudates situated usually not very far from the optic disc; often associated with considerable edema and milkiness of the surrounding retina and impairment of vision depending on the site of the exudate. The salicylates, calomel in broken doses and rest in bed seem to furnish the best treatment. Second, plastic chorioretinitis, another form characterized by pretty sharply defined whitish aggregations of connective tissue, which may be sunk in the substance of the choroid or retina or may project out into the vitreous, even as far as the lens or the ciliary body, attributable to organization taking place in the fibrous exudate. They may develop in conjunction with a disseminated choroiditis or may accompany a retinitis, in which case they very frequently originate in a patch of hemorrhage, or they may also probably occur as a result of hemorrhage without inflammation of either retina or choroid. Once developed the plastic products are apt to remain unchanged for years, though the milder forms may be capable of absorption, with often great reduction of size. Mercury and the iodids seem to be the best treatment. The last form mentioned is retinitis circinata, which may appear in atypical forms, a case of which is here described.

15. Intracranial Tension.—The conditions of intracranial tension are described and illustrated by a case reported by Dennis. He remarks that the tension may be extreme, and mentions an instance where, after trephining and opening the dura, the clot made its way from the lateral ventricle through the track made in the cortex, through the slit in the dura mater and through the trephine hole, with such force as to be projected several feet in the air. The author considers that operative interference is indicated in many cases. In some the indications are very clear, while in others they are somewhat doubtful. A deep coma, in his opinion, calls for operation, and where this does not occur, if the symptoms are gradually increased in severity, it may save life. The problem, however, is hard to solve as to just when operation is demanded in some cases.

16. Venous Hum.—Camac tabulates a number of cases in which venous hum was present with a decidedly marked percentage of hemoglobin. He thinks the cases are not those of

incipient chlorosis. The practical point is that pallor and even a cervical bruit may not indicate anemia. The blood should be examined to determine this point.

18. Pneumonia.—The infectious nature of pneumonia is argued for by Cobb, who points out that it is largely a disease of cities and of overcrowding. He considers that cold and dampness have very little to do with its spread, though dryness is a considerable factor. He thinks the more rational explanation of its more frequent occurrence is that in the severe, dry winters the atmosphere is dryer than at other times and, the weather being severe, people tend to huddle more in places of amusement, in business and in homes, and the air becomes more and more infected. It is a disease, he claims, incident to overcrowding and can only be stamped out by careful attention to ventilation.

19. Climate and Tuberculosis.—Crook speaks of the advantages of climate, and mentions the localities which are suitable for various cases. In the early stage of the ordinary case with slight lung involvement and little constitutional disturbance there is usually improvement with change of climate. Catarrhal cases, with profuse secretion, should have a dry climate, preferably a warm one like Arizona. They usually do poorly in moist climates. Persons of the nervous, irritable and erethistic temperament do better in a marine climate, and should not be sent to high elevations. Sir Hermann Weber advises against sending cases of ulcerative tuberculous laryngitis to high elevations. Most chronic, slowly progressing cases, especially of fibrous phthisis, do best in a marine climate. Cases complicated with heart disease should be kept at a low elevation. Cases involving much loss of lung substance or a large portion of the respiratory area from any cause, usually fare badly at high elevations. The low desert land of Arizona would seem to be the ideal climate for such patients. Puny, scrofulous-appearing youths, not actual, but potential or probable cases of tuberculosis, are generally benefited by prolonged residence in high mountainous regions. There has been considerable difference of opinion as regards the proper climate for hemorrhagic cases. The author thinks that the best observers are beginning to agree that the occurrence of hemorrhage is no bar to high altitude. The tendency to pulmonary hemorrhage does not in itself furnish an indication for or against a particular variety of climate. He is also unable to find evidence that cases of phthisis with albuminuria or marked diabetes should be kept away from high altitudes, but he thinks it would be generally unwise to send them far from home. For those who can not take advantage of change of climate, there should be a sanatorium close to their home.

Medical Record, New York.

20 *The Present Status of the X-Ray Treatment of Malignant Tumors. William B. Coley.
21 *Sigmoidoproctectomy for Cancer of the Rectum. George W. Roberts.
22 A Case of Adenoids with Malaria. Walter F. Chappell.

20. The X-Ray in Malignant Disease.—Coley gives a general review of the *x*-ray treatment, reporting a number of cases. He says in conclusion:

> We find abundant evidence that the *x*-rays have an inhibitory action on all forms of malignant tumors. Yet, the number of cases is insufficient to enable us to state what particular varieties are most susceptible to this influence. So far it would seem that sarcomas primary in the lymph glands yield most readily to the treatment. Superficial epitheliomas might be placed in the same category. Several cases of recurrent carcinoma of the breast have been observed in which the growths have entirely disappeared after prolonged exposures of the *x*-rays. Yet all these cases have been too recent to be classed as cured. In fact, sufficient time has not yet elapsed in a single case of cancer treated with the *x*-ray to justify us in regarding it as cured. While this should, on the one hand, prevent us from reporting patients as cured in whom the tumors have merely disappeared under treatment, it should not, on the other hand, lead us to minimize the importance of these immediate results, even be they no more than a prolongation of life or an alleviation of suffering. One can not witness the marvelous melting away or disappearance of an undoubtedly malignant tumor under a few weeks' or months' treatment with the *x*-ray, without feeling that we have a new and powerful addition to our hitherto scanty means of attacking this disease. The knowledge of this new agent is so slight that there is added hope in our very ignorance. For, by deeper insight into its nature, gained by further experience, we may hope to better utilize its power, and thus accomplish greater results. In the meantime, while the *x*-ray has a legitimate place in the treatment of inoperable cancer, present data do not warrant us in advising the method in primary operable cases.

21. Sigmoidoproctectomy.—Roberts' article describes the technic in detail, for which the reader is referred to the original. He reports several cases.

American Medicine, Philadelphia.

March 21.

23 *Excision of the Superior Maxillary Under Medullary Narcosis. A. W. Morton.
24 *On the Transportation of Cellular Emboli Through the Thoracic Duct into the Lungs. W. G. MacCallum.
25 *The Albumoses: Their Clinical Significance Viewed from a Modern Standpoint: Their Detection and Distinction from the Other Proteids Found in the Urine as a Means of Lowering the Death-Rate in Obscure Suppurative and Other Diseases. Thomas J. Yarrow, Jr.
26 *Influence of Marriage and Pregnancy on Diseases of the Heart. M. J. Backenstoe.
27 The Report of a Case of Malignant Edema. Isaac R. Trimble.
28 *Briefs on Physical Training. G. Frank Lydston.
29 Some Problems of Preventive Medicine. (Concluded.) Burnside Foster.
30 National Bureau of Medicines and Foods: For Pure and Honest Drugs, Chemicals and Foodstuffs. Philip M. Jones.

23. Spinal Anesthesia.—The case reported by Morton is of interest, as showing how high an operation may be performed under this method. The operation is the same and one of the illustrations is the same as was reported in THE JOURNAL of Nov. 8, 1902. He thinks the advantages of the method are that the anesthetizer is out of the way of the operator; avoidance of the danger of blood and secretions getting into the lungs and causing later pulmonary complications; the facts that heart disease or lung or kidney complications do not prevent it, and finally, that the shock is not so severe. He has used it in 929 cases; 76 were operations above the diaphragm, and many were similar operations to that reported.

24. Cellular Emboli in the Lungs from the Thoracic Duct.—MacCallum has not found any description of extensive affections of the lungs due to the cause suggested in this title, but reports a case, which he finds best explained in this way. He says we have here evidently to deal with multiple hemorrhagic infarctions of the lungs, produced by plugging of the branches of the pulmonary artery with masses of cells of the type of the lymphoid cells and larger mononuclear phagocytic cells. What is the origin? He suggests that this can be best explained by their being carried through the thoracic duct and into the subclavian vein. He thinks the study of such possibilities has not been made sufficiently thorough, though they seem to have some important bearings.

25. Albumoses.—Yarrow gives a lengthy article discussing the tests and clinical significance of albumoses in the urine. He thinks we have in them a very valuable aid in diagnosing concealed pus collections which has not been, to any great extent, taken advantage of, and illustrates his views by a number of brief reports of cases. He enumerates a number of conditions in which this examination might be of value. The recognition of the fact that pus is often present may relieve a situation of some of its danger and offer a chance for early operation. He is opposed, like Deaver, to placing absolute reliance on the presence or absence of leucocytes, and thinks the additional test is of some value.

26. Marriage and Heart Disease.—The question as to whether marriage should be advised in case of heart disease is noted by Backenstoe, who thinks we should study the degree of the disorder, especially if it is giving rise to cardiovascular symptoms, such as hemoptysis and dyspnea, and in these cases marriage should be advised against. The situation of the patient as regards occupation and environment should be taken into account, and the ability to keep quiet in case unfavorable symptoms make their appearance. If the conditions are all favorable there is no objection, but the condition of the heart should be carefully watched. All effort or fatigue should be avoided in case of pregnancy. He attributes considerable importance to the preventive action of a mixed milk diet, the milk being consumed at the rate of two quarts a day. He would not offer serious objection to marriage in the absence of cardiovascular symptoms of a certain gravity when the patient is willing to promise to follow this diet in case of pregnancy.

28. Physical Training.—The concluding article of Lydston reviews the more valuable forms of athletics. He thinks that

outdoor exercise is excellent, better than gymnasium practice, and the element of play should come into it as an essential. A person should have a thorough physical examination before undertaking practical athletics. The ideal form of outdoor exercise is boxing for men, and fencing is the ideal form of athletics for women. Wrestling, within proper bounds, is especially good, but it is hard to thus restrict it. Non-professional ball playing is good. Football, he thinks, is too brutal, especially as there is a chance of rowdyism. His conclusions are given that physical training is an important part of preventive and curative therapeutics, and should be taught in medical schools. Such departments of medicine as neurology and surgery, particularly orthopedic surgery, are especially enriched by a knowledge of physical training on the part of the physician. The aim should be to utilize the inherent physical capital of the individual and bring it up to the physiologic standard. Physical and intellectual development should go hand in hand. He thinks these would tend to reduce pauperism and crime if properly followed. Comparative measurements are not to be relied on. Specialism in muscle building is justified only in so far as it tends to bring up any given portion of the body to the relative proportions normal to the particular individual—to the normal symmetry. Occupation should be considered. The highly trained muscles are useless and perhaps injurious to those of sedentary occupation, and tend to muscle and visceral degeneration, and the tendency of certain individuals to become muscle and joint bound is a point which should be guarded against. The athletic habit should be guarded against, as well as athletic overstrain. The ideal system of muscle building is that which involves the least expenditure of time and the use of the least apparatus. Abdominal muscle development is the keynote of success. Of practical athletics the best forms are boxing, fencing and handball. All are best performed in the open air. Golf is admirable in this respect. The element of play, diversion of the mind and cheerful companionship is a *sine qua non* in obtaining the best results.

Boston Medical and Surgical Journal.

March 19.

31 An Account of Dr. Thaddeus MacCarty—A New England Country Doctor of Pre-Revolutionary Days. Edited by Burnside Foster.
32 *Lipoma Arborescens. Charles F. Painter and William G. Erving.
33 Suppuration of the Frontal Ethmoid, and Sphenoid Sinuses, with Brief Report of the Treatment of 237 Cases. (To be continued.) Edgar M. Holmes.

32. **Lipoma Arborescens.**—This disorder, consisting in fatty growths of the joints in connection with arthritis and tuberculosis, is described by Painter and Erving, who report seven cases. The clinical symptoms are those of a foreign body, and the authors think that in the absence of other evidence of tuberculosis it is reasonably certain that isolated villous hypertrophies without more symptoms of joint disease will not be found to be due to tuberculous infection in the cases they report. They briefly review the literature, remarking that while the condition has been noticed in pathologic works it has received very little attention in surgical text-books. The clinical picture is that of a more or less swollen joint without any signs of acute inflammation, and most commonly without even any excess of fluid. The growth sometimes produces pain; more often pain is absent, but there is often impairment of motion from locking of the joints. The tumors are attached to the synovial membrane by a pedicle, usually slender, consisting mainly of blood vessels in a mass of small round cells. In structure they vary from a soft, fatty to a tough, fibrous growth. They are very vascular, and after removal shrink to a great extent. The bulk of the mass consists, however, of normal adipose tissue, through which run bands of varying width of fibrous tissue. They adopt practically Stieda's conclusions that it is etiologically a chronic inflammatory condition of the joint. It is not a lipoma in the sense of being a new growth, but is merely a hypertrophy of normal pre-existing tissue, a hyperplasia and fatty degeneration to an extreme degree of pre-existing synovial tabs. Diagnosis is not certain in an unopened joint. Prognosis of spontaneous healing and recovery of joint function is unfavorable. They disagree, however, with Stieda's conclusions, in giving less importance to tuberculosis in the etiology.

38 Corneal Burns. E. M. Marbourg.
39 Nervous and Mental Phenomena of Arteriocapillary Fibrosis and Atheroma. J. E. Courtney.
40 Chloroform Anesthesia. E. T. Duke.

37. **Treatment of Pneumonia.**—Morris reviews the various treatments of the past and those recommended at present. He does not find that creosote bears out the praises that have been given it. More extended experiments should be conducted. Quinin has been advised and a very low mortality reported under its hypodermic use, but it should be further tried. Antipneumococcic serum has not met the full expectations, though many are hopeful of better results. Saline infusions are also similarly noticed. He advises to treat the patient and then the pneumonia incidentally. If the patient is strong and robust, depletion at the outset, calomel and soda, 5 grains each, followed by magnesium sulphate, morphin to relieve pain, pleasant surroundings, equable temperature with an abundance of pure air, dry cold to chest to relieve temperature, followed by the tepid bath, if necessary. Beginning on the second or third day concentrated nourishment every three hours, day and night. Strychnin, digitalis and whisky if heart shows any indication of weakness, and if collapse is imminent, hot applications and saline infusions. If the patient is of low resisting power, do not deplete, but support and nourish from the commencement. If the patient is accustomed to drink, continue it in increasing dose. He thinks that following such a course one has done all that our present knowledge warrants.

51 A Case of Hypertrophic Cirrhosis of the Liver, with Splenomegaly in a Young Man. Augustus A. Eshner.

46. **Prognosis in Pneumonia.**—French first notices the increase of pneumonia, its significance, if any, and the reduction of its mortality. He emphasizes the prognostic elements as, first, age, which he finds is well known, advanced years influencing mortality. As regards catarrhal pneumonia, the rule of Ziemssen that the danger increases in proportion to the youth still holds good. As regards sex, he thinks statistics show, if anything, a rather greater mortality among women, though the number of cases occurring is much less. Habits and consti-

tution have much to do with it. The percentage of deaths is large among alcoholics and degenerates. Pregnancy adds to the danger, as well as heart disease. Traumatic pneumonias are very fatal. Fleshy people suffer more than thin ones. The amount of lung tissue involved also influences mortality, the danger increasing with the amount. The upper lobes are somewhat more dangerous than the lower. The involvement of both lungs makes the prognosis more serious. Of the various complications, heart disease as well as meningitis is almost always fatal. Affections of the kidneys are dangerous. Catarrhal or capillary bronchitis is always a dangerous complication. Something is said also as regards the severity of the epidemic, which is emphasized by Osler, who considers the toxemia the most important element in the disorder. Of the individual, symptoms most reliance is to be placed on the pulse. A pulse in the adult of over 120 or in children of over 140, is of grave significance, according to Quain. Marked irregularity in force or rhythm, especially in the young, is a bad sign. The table given by Sears and Larrabee seems to illustrate the law that the mortality in pneumonia is in direct ratio to the frequency of the pulse. The line of average mortality seems to be drawn at a pulse rate of 130. Below that the mortality is less than the average of 35.9; above it is higher than the average. The variations in respiratory rate follow much the same law, though the importance of respiration is much less than that of the pulse. The importance of temperature as a prognostic element is generally recognized as second only to that of the pulse, but it does not follow the same laws, according to Sears and Larrabee's figures. It seems to show a steady decrease of mortality corresponding to a rise of temperature up to 105, after which the mortality again rises, increasing with the temperature. That the mortality should be so great below 100 would be more remarkable if the number of cases were larger. The line of comparative safety would seem to be between 103 and 105, with the danger increasing above and below these figures. As regards treatment, there seems little from their studies that is encouraging, and they conclude that pneumonia is uninfluenced by treatment. French, however, is disinclined to accept this conclusion, and hopes the time will soon come when treatment will be universally admitted to be an important element in the prognosis of pneumonia.

47. Yellow Fever.—Finlay claims that he had pointed out the principal facts in regard to yellow fever from his clinical observations, that were subsequently determined by the yellow fever commission, differing only slightly. He thinks his right of priority has been tacitly denied by the Army board, their work only verifying the conclusions he had already reached and the results which have been so brilliant were those he had already pointed out as being probable.

57 A Key to the Home Modification of Bottled Milk. J. F. Connors.
58 Report of a Case of Tetany. T. J. Elterich.

52. Mongolian Idiocy.—Muir has investigated 26 cases and discusses the condition generally. He found a history of drunkenness in 4 cases of his 26; 4 cases with either a family history of insanity or eccentricity; in 3 the father was violent in temper; in 1 the father was a suicide; in 4 the mother was a neurotic and excitable; in 3 cases there were twins or triplets in the family; in 3 the intra-uterine movements were hardly felt; in 3 the mongol was premature; in 1 a previous child was anencephalous; in 8 the labor was prolonged or complicated; and in about one-half the cases a statement of fright or worry was reported. Only 38 per cent. of the cases had tuberculosis in the parents and only 3 had syphilis. In 15 cases the mother had bad health during pregnancy. Fifteen were males and 11 females. He describes the symptoms, appearances, and the data as to physical development of the patients. Fourteen of the cases were idiocy of the low grade, 4 medium, and 7 of a high grade. Speech came late. The best-educated one knew his own name, could spell "Monday," and knew the year and month, knew all the figures and some of the letters. The prognosis seems bad in these cases. Treatment has been of no avail and thyroid treatment was useless.

54. Circulatory Failure.—This is a brief preliminary report dealing with circulatory failure from direct loss of blood, shock, loss of blood and sepsis combined, and sepsis in acute infectious disease. In shock and hemorrhage it would appear that saline infusions and also hypodermoclysis can be promptly and safely used. The infusion has an immediate effect and the hypodermoclysis improves the circulation in five to ten minutes. Both are more rapid in effect than drugs and apparently increase the effects of the drugs given. It is safe to continue with the saline until the pulse is of good quality, and then to stop it. From a study of septic cases treated by saline infusion it seems that it would be safe to reserve this for septic cases where there has been decided loss of body fluids, as in severe choleraic or typhoid diarrhea. In cases of sepsis without loss of body fluids and with an imperceptible pulse and rapid respiration and a very rapid thumping of an undilated heart, saline infusions and hypodermoclysis may be warranted, but should never be employed in a routine way or when the heart's action is hampered by pericardial effusion. Seven of the 8 septic cases—the basis of this report—were looked on as hopeless and the ultimate recovery of 4 out of the 8 was in every way satisfactory, considering the gravity of the cases. Enteroclysis properly carried out with Kemp's flexible double current catheter, fifteen minutes' flow of water at 110 F., seems to be an absolutely safe method of combating circulatory failure in sepsis. It stimulates the kidneys, eliminates poisons, induces intestinal absorption of water when the body craves for it, reduces temperature to a certain degree and seems to be indicated as a routine treatment in all septic conditions, even if the kidneys are unimpaired. In severe anemia, Caillé has found that enteroclysis is followed by an actual improvement of the blood mixture, independent of the administration of drugs. In conclusion, he emphasizes that circulatory failure is not always heart failure, and more attention should be given to this fact. Enteroclysis properly carried out should be universally adopted in the practice of medicine as a therapeutic measure of undoubted value when increased elimination through the kidneys is desired, as in all forms of infective disease and in faulty metabolism generally. It may also be given in connection with medicines.

59 *Report of Two Cases of Bullet Injuries to the Left Lateral Half of the Upper Portion of the Spinal Cord. J. T. Eskridge and Edmund J. A. Rogers.
60 *A Study of Sensations in Motor Paralysis of Cerebral Origin, Based upon Thirty-five Cases. Alfred Gordon.
61 Report of a Case of Mamillai Tremor of the Head. John K. Mitchell.

59. Bullet Wound of the Spinal Cord.—Two cases of gunshot wound of the upper left lateral half of the spinal cord are reported by Eskridge and Rogers. The direct cerebellar and the crossed pyramidal tracts were cut across in both, but the extensive inflammatory softening and the hemorrhagic infiltration came on early and the rapidly fatal termination prevented the valuable data as to localization which was desired. Still some interesting points were noted suggesting that there are fibers in the cervical region of the spinal cord that aid in elevating the upper lid of the eye of the same side, and in modifying the size of the pupil of the opposite side. These results are opposed to what has been found by experiments, but the conditions are somewhat different.

60. Sensations in Motor Paralysis.—Thirty-five cases of hemiplegia have been studied by Gordon, with special reference to sensory disturbance and their cerebral localization. He finds that in all the cases there was more or less sensory involvement. The order in which the sensory involvement was most frequently observed is summarized as follows:

Touch—upper limb, trunk, lower limb, face. Pain—upper limb, trunk, lower limb, face. Temperature—upper limb, lower limb, trunk, face. The stereognostic sense was disturbed in 29 cases out of 35. In 22 the loss was complete. The greater the involvement of the other sensations the more marked the astereognosis, which he thinks favors the conception of the stereognostic sense as depending on integrity of the three cardinal sensations. Paresthesia was present in only 12 cases. The special senses were involved only in 11. The longer the date of motor paralysis, the less the sensory disturbance He is forced to the conclusion that hemisensory disturbances probably always accompany motor paralysis of cerebral origin, no matter to what extent the latter is marked; paralytic or even only paretic symptoms will at the same time show sensory symptoms. The method and persistence of investigation will determine this fact.

62 Study of the Cadaver of a Woman Who Died in the Sixth Month of Pregnancy. J. Clarence Webster.
63 The Technic of Vaginal Hysterectomy in Cases of Pelvic Inflammation. William R. Pryor.
64 *Hysterectomy in Puerperal Septic Infection. Charles Jewett.
65 *Hydrops Tubæ Profluens. Henry D. Ingraham.
66 *Version or Forceps, Which? S. Marx.

64. **Puerperal Sepsis.**—In this paper Jewett tabulates all the material that he has been able to obtain in regard to the effects of hysterectomy in childbed sepsis and finds a total of 116 operations. In 4 the result was not stated; of the remaining 112, 59 resulted successfully, that is, 52 per cent. In 34 operations after term labor, there were 17 recoveries, 50 per cent., and in 28 after septic abortion there were 11 recoveries, or 39.2 per cent. In 25 cases in which no extrauterine structures were involved, 19 were saved, 76 per cent. Of 12 patients in whom peritonitis was found at operation, 2 or 16.6 per cent. recovered; in 12 cases where bacteriologic examinations were made, streptococci were found. In 17 cases operated on the first week after delivery, there were 64.7 per cent. of recoveries. Seventeen operations during the second week gave 52.9 per cent. of recoveries. In 54 abdominal hysterectomies there were 27 recoveries, or 50 per cent.; and in 29 vaginal operations there were 14 successful results, 48.8 per cent. In 3 cases of supravaginal amputation with extraperitoneal treatment of the stump, all the patients recovered. No instance of recovery appears where there was a clearly-established diffuse peritonitis. The experiences presented justify the conclusion that while hysterectomy is very seldom demanded in the treatment of puerperal septic infection, the operation can not be wholly rejected. In rare instances it is clearly indicated. He gives a table of cases.

65. **Hydrops Tubae Profluens.**—Two cases are reported by Ingraham, one due to hemorrhage in childbirth, and the other probably too long-continued constipation. In the first case there has not been any relief. In the second, relief of the constipation caused relief of the symptoms, which recurred when the condition of the bowels was neglected.

66. **Version or Forceps.**—Marx favors the use of version in preference to forceps and would not sanction the application of forceps to the head above the brim, except when rupture of the uterus exists or is impending, or when we are dealing with a tetanized organ from which the waters have long escaped.

73 The Heart and Life Insurance. J. C. Sullivan.

69. **Septic Uterus.**—Marcy recommends in a case of actual abortion the leaving alone of the placenta if it is not detached or can not be detached as a whole. Examine the patient at least twice every day as to temperature. If there is a slight rise or if we can not see the patient often, then a clean fountain syringe with a sterilized glass uterine tube attached, pouring in one-half pint of hydrogen dioxid, diluted with one-third sterile warm water, allowing it to flow while introducing the tube into the uterus to prevent air entering the uterus is recommended. The os must be sufficiently open to allow the free escaps of the fluid. There should also be ready a pitcher of hot sterile water in which has been dissolved a few tablets of potassium permanganate with which to continue the douche, repeating this procedure as often as necessary. He claims that this method will be satisfactory, and says it bleaches septic debris in the uterus and renders it odorless and harmless, without doing violence to the uterus itself. In the discussion following the plan was criticised by Dr. C. B. Reed.

February.

74 *A Brief History of Bacteriological Examinations in Suppurative Otitis Media, with Remarks upon the Relative Virulence of the Various Micro-organisms. Wendell C. Phillips.
75 *The Treatment of Acute Otitis Media. F. Bezold.

74. **Otitis Media.**—Over twenty different micro-organisms are noted by Phillips as having been observed in otitis media. The most virulent are the streptococci. Next to them he considers the diplococcus intercellularis meningitidis. The pneumococcus is frequently found, but is not to be considered especially virulent. It is probably more frequently present in purulent otitis media than any of the others.

75. **Treatment of Acute Otitis Media.**—Bezold notices several points in regard to the treatment. He insists on determination of the site of the perforation which, in his experience, was most frequent in the upper and lower posterior quadrants. He has never observed an acute perforation in the Shrapnell membrane. Multiple perforations or a marginal one, indicate tuberculous infection. He comments on the anatomic peculiarities of the pneumatic cells as affecting the duration of the disease. They differ in size and number in different cases. In ordinary tubal occlusion, if the serum is not mechanically removed and brought to absorption by the repeated use of the Politzer bag, he would practice paracentesis in the lower posterior quadrant of the ear-drum, preceding it by mechanical cleansing of the ear and irrigation with a 5 per cent. carbolic solution. The serum which exudes is removed with cotton tips, and if the remainder is not forced into the meatus by the air-bag, he would use an external air douche to force it into the nasopharynx. In ordinary acute otitis media he would operate by paracentesis and use the air douche and inflate a small quantity of boric acid powder. He considers a careful drying of the canal by dipping out the discharge with cotton tips to be very important. If acute middle-ear suppuration lasts more than two months and there are complications present which will prevent its spontaneous cure, he does not hesitate to proceed to operation, especially if pain or swelling are present below the mastoid. He objects particularly to irrigation through the catheter and to the packing of the ear canal, the so-called dry method.

79 Some Points in the Differential Diagnosis of Cancer of the Stomach. Collins H. Johnston.
80 Auto-intoxication as a Cause of Gingivitis. J. C. Maxwell.

76. **Tuberculosis.**—Shurly advocates the sanatorium treatment of tuberculosis in some advanced cases, though the home treatment he considers is preferable, especially with salubrious environments, for children and young adolescents, as also among the educated well-to-do class of people during the early stages of chronic pulmonary disease. When septic poisoning has occurred, however, greater relief may be expected from sanatorium life and discipline. He thinks it would be well for general hospitals to have an annex properly built for the accommodation of these cases. He deprecates the panicky feeling about its contagion and thinks that possibly the prevalence of the disease is overestimated.

77. **Epilepsy.**—Ostrander holds that the prevalence of epilepsy may be diminished by greater attention on the part of physicians to the remote causes, especially the nutrition of children

in early life, which he thinks has much to do with the degeneration of their nervous system and in the production of later epilepsy. He also objects to the use of nerve sedatives or powerful drugs to prevent or abort convulsions. It is not always advisable to do this. The proper treatment may be summed up as régime and discipline, and since these can not always be controlled at home the colony treatment is the ideal one for a large class of these unfortunates.

78. **Typhoid Fever.**—Safford reviews certain points in typhoid fever, the diet which he finds of late years has come to be more liberal, at least according to the recommendation of certain authorities As regards the baths, he thinks the opponents and adherents of the Brand method are compromising on the tepid bath, though in cases of hyperexia the case may be a little different. The mere lowering of temperature, however, is not considered as important as formerly. Intestinal antisepsis is also mentioned. He thinks in using means for this, we should take special care as to the condition of the kidneys. The various reactions, the diazo and Widal reactions are noticed. The former may be of value in the diagnosis and prognosis. Its late appearance and persistence would indicate acute tuberculosis. The reappearance of the reaction after its disappearance for a time may help to determine the question of relapse as distinguished from the fever of complications. Its occurrence in other diseases, of course, is not to be forgotten, and is responsible for the neglect into which it has fallen. The Widal reaction is less questioned of late, but still it is not absolutely reliable, and often appears but late. If its limitations are recognized it may be used with advantage. In conclusion he calls attention to the elimination of bacteria through the urine as a possible cause of the continued danger of infection, and the question of typhomalarial fever, which he holds does not exist.

82 Report of a Case of Acute Leukemia. W. B. Thistle.
83 A Case of Hemorrhage from Stomach and Bowels Complicating Chronic Bright's Disease. W. T. Gemmell.

81. **Non-Identity of Human and Avian Diphtheria.**—After first noticing the experimental work of others, Harrison gives his own experiments, in which he inoculated fowls suffering from roup with diphtheria antitoxin without effect, and also healthy fowls with cultures of the Klebs-Loeffler bacillus, which were similarly ineffective. He also finds that he did not infect rabbits and guinea-pigs with false membrane taken from birds, and he has kept rabbits and guinea-pigs in cages with diseased hens and they have never taken the disease. He also finds that the structure of diphtheria membrane in man and fowl is quite different. In the former it consists of necrosed epithelial cells and inflammation of underlying connective tissue with abundant fibrous exudation. In fowls, however, it is entirely composed of pus cells, some small masses, and débris of epithelial cells and bacteria; micro-organisms which stain by the Gram method were seldom found. Attempts were made to increase the virulence of the hen diphtheria micro-organism, which he calls the *Bacillus cacosmus*, with success, producing roup in the hen at pleasure by inoculation from roupy pigeons. He finds also that the same disease can be produced in healthy hens by the use of the *Bacillus pyocyaneus*.

89 The Modern Hospital. J. H. Phillips.

86. **The Heroin Habit.**—The published statements that heroin does not cause the habit of using it are contradicted by Pettey, who reports cases of heroin addiction. Out of the last series of 150 drug-habit cases coming under his care, 8 had been addicted to the use of heroin, 3 were initial habits, the patients not having been before addicted to any drug. He finds the same difficulty in breaking off the habit that we have in morphin. In his experience, it differs from morphin in having less of the primary stimulating effect, being more prompt and certain as a hypnotic, and less powerful and prompt as a pain reliever. It does not so greatly impair digestion or assimilation or interfere with secretion and excretion, but it does cause constipation and interfere to a hurtful degree with the nutritive function, and its prolonged administration is liable to produce the opium habit.

1. Tuberculosis.—Williams first notices the pathology and calls attention to the defenses of the air passages to protect the lungs, the tonsils, larynx, nose, especially the trachea, and to a certain extent the primary bronchi. The last two have three layers of epithelium which have to be penetrated, the top one armed with cilia, producing a strong current outwards, thus preventing the tubercle bacilli from descending. The amount of germs that must be inhaled is very great, and yet we note that comparatively few of those who inhale them suffer from pulmonary tuberculosis. He notes in this connection the well-known experience at the Brompton Hospital. The chief causes of tuberculosis, however, are two: 1. Impure air; 2, lack of proper food Frequently deprivation or starvation is the starting point of a tuberculous infection. He gives a striking instance of this in a man who had his esophagus injured by sulphuric acid, embarrassing swallowing. When death occurred, as it did shortly, his lungs were found filled with tubercles. Special conditions that favor tuberculosis are noticed, such as ossification of ribs, noted by Freund, and pleurisy. Why the apices are first involved is probably due to a certain amount of obstruction and stagnation in the upper lobes. The first place where a tubercle lesion is likely to be found is near the upper lobe about one and a half inches below the posterior apex in the superscapular region. Thence it spreads by continuity, by the lymph, by the circulation (which is the most serious and rapid method and the one which occurs when the meninges are infected) and lastly by re-inhalation of sputum. The points of diagnosis are mentioned, history, physical signs, sputum examination, diagnosis of pneumonia and of bronchitis, which in cases of catarrhal infections is sometimes difficult. As regards typhoid fever, this has more bearing in acute tuberculosis than on the ordinary form.

2. The Infectivity of Phthisis.—Hillier notices the different methods of the infectivity of phthisis, the chief one being the inhalation of sputum, and offers the following conclusions from the evidence he has adduced:

I hold it conclusively established that both dried tuberculous sputum dust and the minute drops coughed out by the consumptive are capable of conveying the infection. The precise proportion which each factor plays in this infection it is difficult to estimate, but there are two points in connection with the cough infection which, I think, are of special importance.

In the first place, the minute cough-sprayed drop which contains a tubercle bacillus probably in the majority of instances contains that bacillus in a condition of a high degree of virulence. The bacillus contained in the minute sprayed drop comes straight from its natural soil, and is probably more potent as an agent of infection than that contained in the dust particle which has been exposed to desiccation, and in the majority of instances to some degree of light.

Secondly, those sprayed drops which fall to the ground, or are deposited elsewhere, although they may not carry with them a large number of bacilli, nevertheless deposit such bacilli as they do carry, under conditions which ensure their rapid desiccation and formation into the smallest particles of dust. These minute drops thus add their quota of bacilli to that quantity of minute dust which alone is capable of inhalation.

With reference to the extent of the infectivity of phthisis, while I hold it to be an infective disease, I do not consider that the degree of this infectivity is a high one. But as against this we must set the fact that phthisis is a chronic disease, and that the chance of conveying the disease often extends over years.

Of those exposed to infection for brief periods only a very small minority are infected. Of those exposed for days, weeks, even months in a small confined atmosphere many escape. Why many escape and others do not escape, has not yet been scientifically demonstrated. But this we know, that be the causes of apparent immunity what they may, no person can develop tuberculosis who is not exposed to the possibility of invasion by the tubercle bacillus.

3. Human and Bovine Tuberculosis.—We have already given Raw's views in The Journal of February 28, '99, p. 609.

4. Phthisis and House Infection.—Johnson analyzes a number of cases of tuberculosis occurring in old houses in Richmond. He finds, out of 11, 6 arose in old ill-ventilated, narrow-windowed, sunless or dusty houses; 2 arose in houses known to be tenanted by persons suffering from phthisis; 2 were imported cases living in old houses in which the disease was rapidly accelerated; one is an imported case residing in a modern house. In not a single instance does the disease arise *de novo* in modern, decently-kept houses. It is bad building and bad management that make tuberculous houses. The modern, well-cleansed house, he says, offers no risks whatever.

5. Diet in Tuberculosis.—Tuberculosis is characterized by generally widespread toxic changes. The tissues in this condition are not capable of elaborating food stuffs satisfactorily. One advantage of the meat diet in addition to its directly curative effect is that it supplies organically combined iron and renders the administration of other organic hemetics unnecessary. A rational dietary in phthisis is not indiscriminate stuffing nor

indiscriminate lessening of food, but consists in furnishing a diet rich in the proper constituents. The special advantages of a meat diet in this relation is that, besides containing the nuclear bodies which have a directly stimulative action, it contains also proteids which have a high nutrient value. Sufficient fat and carbohydrates should be given to meet the physiologic needs and should be increased as metabolism and absorption improve, to the maximum which can be elaborated.

6. Sanatorium Treatment.—The Nordrach method is here discussed by Ilichens, who claims that it is the duty of the practitioner to cultivate his observations and diagnostic skill so as to recognize the earliest signs of tuberculosis and as soon as diagnosis is made put the patient on the most thorough open-air treatment that his circumstances will allow. If the patient is poor much can be done at home, keeping his windows wide open day and night, and being under an open shelter or in a chair in the garden with a sufficient and nourishing diet. If well-to-do the patients should be sent, if possible, to a sanatorium and the best plan would be to have one in the climate in which they have permanently to live. Even in the slightest cases a very long period should be devoted to treatment and rest from work. Even after an apparent cure there are many tubercular foci which are apt to be left. If more time can not be given even one or two months at a sanatorium will be a training, and after leaving the patient should live an open-air life for one or two years. If poor one must do the best we can for them by allowing them to take up some light occupation out of doors.

10. The Problems of Diabetes.—White notices a number of things which are required to complete our knowledge in regard to glycosuria and diabetes: 1. We must have some better methods of recognition of dextrose in the urine as easy as small amounts of albumin are discovered. We want to know something more about glycoronic acid and whether people that pass it later become glycosuric; the connection of exophthalmic goiter with glycosuria is another question. We want information about the occurrence of other sugars than dextrose in the urine. Very few if any observations have been made in England on pentosuria and the question is asked whether the passing of lactose in the urine may lead to diabetes or not. The more accurate use of the term diabetes is noted as desirable. We need to find out whether alimentary cases of glycosuria become real diabetes mellitus, and the fact that many diabetics can utilize levulose much better than dextrose is of interest. The question arises whether other sugars might not be utilized in this disease. Another point mentioned by White is the extraordinary fact that patients put on a strictly carbohydrate-free diet may, if a little carbohydrate is given, excrete far more sugar than has been given. We also want an explanation why sugar disappears when coma comes on and also why the body fails to utilize dextrose when it has not lost the general power to oxidize. Coma is a matter of great importance. There is considerable evidence that it is closely associated with oxybutyric acid, which is always abundantly present and the fact that coma is sometimes benefited by giving alkalies is suggestive of this. The origin of oxybutyric acid is also of interest. There are no special anatomic changes in the nerve centers or in the peripheral nervous system with diabetes, but the fact that the knee jerk is absent in 50 per cent. of diabetics is difficult to explain. As regards treatment, the author thinks that in many instances the dieting has been too strict. Many cases are not allowed enough fat, and he thinks that the use of a large amount of alkali is excellent in the treatment of coma.

11. Salicylic Acid and Food Preservatives.—MacAlister and Bradshaw have experimented on the effect of salicylic acid in food stuffs and find that it exerts about the same retarding influence on digestive processes as does kitchen salt. Its effect on nutrition can not be very well elucidated by laboratory experiments. The only practical method was to take it themselves and give it to others. One of them took a dose of five grains of the pure acid every day for a month without any ill-health following, and a smaller quantity given to children every day with their dinners did them no harm. It is a curious fact that insects do not appear to be harmed by taking salicylic acid dissolved to saturation in syrup. Kolbe, quoted by Binz, while directing attention to the strong antiseptic properties of the drug, says it is not poisonous to human beings and in proof of this took himself and gave to others from 1 to 1.5 grams a day and in some cases for nine months together without apparent injury. The objection that it is injurious to the mucous membrane on account of its acid quality alone can not be maintained. The argument is fallacious that any substance which has a deleterious action on one kind of protoplasm must act deleteriously on all kinds. Some micro-organisms require oxygen while others are killed by it. While the harmfulness or not of antiseptics is a matter of disagreement, authorities are agreed as to the harmfulness of food in decomposition, and we may be courting a greater evil by barring their use. They maintain that the use of salicylic acid enables the manufacturer to place on the market, wholesome, agreeable and inexpensive articles of food for persons who can not afford the more costly luxuries and which take the place of intoxicating drinks. They say this with due consideration and with, they trust, an adequate sense of responsibility.

12. Anti-Streptococcic Serum in Endocarditis.—From a study of the effects of antistreptococcic serum in endocarditis including two tabulated statements of organisms present before and after the use of the serum, Ogle says, that if any conclusion can be drawn, perhaps they will be:

1. That the gravest symptoms combined with streptococcic infection, even of the blood stream, are not incompatible with recovery if treated by injections of anti-streptococcic serum. 2. That this is true also in malignant endocarditis, but that here the chances are probably less favorable on account of the colony of micrococci involved in the vegetations in constant contact with the blood stream. 3. That in malignant endocarditis staphylococci are frequent, or a mixed infection of staphylococci and streptococci. 4. That if an examination of the blood be negative it would be prudent, therefore, to use injections of anti-staphylococcic, together with anti-streptococcic serum.

14. The Etiology of Sleeping Sickness.—Castellani finds an organism in this disorder in the blood and the cerebrospinal fluid which he thinks a new variety of streptococci. While the streptococci are hard to differentiate, the cultivation on gelatin he thinks is sufficient to differentiate it from all others.

22. **Coincidence of Oxaluria and Indicanuria.**—Moraczewski, at Carlsbad, has examined 439 persons to determine the frequency of this coincidence. He found that oxaluria accompanied indicanuria in 84.3 per cent. of the 376 cases in which the latter was noted, and in 100 per cent. of the 23 cases in which the indicanuria was extremely pronounced. Indicanuria was present in 74.2 per cent. of the 398 cases with evident oxaluria. In only 15 per cent. of the total number was oxaluria found without indican, while they coincided in 84 per cent. In only 10 per cent. was indican noted without oxaluria. The subjects were those with uric acid diathesis or oxaluria *sui generis*; or diabetics, the latter representing 23 per cent. of the total number. The digestion was apparently excellent in the majority. Altering the diet and administering alkalies modified both in the same proportion. The diet proposed by Rosin for oxaluria avoids spinach, cabbage, milk, eggs, tea and cocoa. Acid reaction is obtained with meat. This is supplemented by small doses of magnesia and copious drinking.

24. **Diagnosis of Multiple Stenosis of Intestines.**—Schlesinger reports the successful diagnosis of 4 cases of this condition. It was based on the repeated observation of the abrupt, visible erection of certain loops of intestines at a distance from each other, with no palpable rigid intestine between. The assumption of multiple stenosis is confirmed by the recurrence of these "huge snail shells pushing out the abdominal integument," at about the same place each time. Also by the subsidence of a protruding loop with borborygmi and rumbling noises. A history of syphilis or tuberculosis is an aid to the diagnosis. One of his patients had a stricture at twelve points, but recovered after "exclusion"—*Ausschaltung*—of 6.5 feet of the small intestine.

25. **Metameres in Syringomyelia.**—Ferrannini establishes by the findings in 2 cases which he describes that the sensory disturbances are of a type corresponding to the spinal cord or the roots according as the lesions are situated in the former or in the latter.

27. **Differentiation of Inflammation of Pelvic Cellular Tissue.**—Loeb reports a case diagnosed as an inoperable sarcoma which proved at the autopsy to be syphilitic gummata of the liver. Lancereaux has reported another of stenosis of the rectum in an anemic woman of 36, from compression by a mass adherent to the pelvic wall, assumed to be of malignant nature. There were no traces or history of syphilis, but the patient entirely recovered under potassium iodid, 3 gm. daily for two months.

28. **Extravasation from Congestion.**—A supposedly healthy young man awoke from an afternoon nap finding himself on the floor instead of the bed, and with his face, mouth and neck somewhat swollen and dotted with punctate hemorrhages, down to a red line around his neck. He had also urinated. The physician diagnosed the case as a first attack of epilepsy occurring during sleep, the congestion and swelling of the head aggravated by the neckband of his undershirt, loose under ordinary conditions.

29. **Phosphometer.**—Jolles has improved and simplified his apparatus for detecting phosphorus and phosphoric acid in the blood. The description is illustrated.

30. **Hereditary Heart Affections.**—Ferrannini remarks that in the history of certain families general dyscrasias, nervous affections, nutritional disorders, cardiac defects and vascular and morphologic anomalies appear before us as in a kaleidoscope, recurring in various combinations. He gives the history of one family for three generations, including 42 individuals. In 31 per cent. there was some cardiac affection, and only 7 per cent. were healthy. He attributes the inheritance of heart disease to an embryologic substratum in inherited insufficiency of the histogenetic power of the mesenchyma.

31. **Diagnosis of Hourglass Stomach.**—The usual signs of this condition may be lacking and yet it is possible to differentiate it as shown by the case described by Rosenfeld. The patient was a pale, thin man of 28. Functional tests showed HCl in abundance, but otherwise nothing abnormal in the stomach. There was no palpable constriction and the fluid contents of the stomach could be siphoned out with a soft sound. Radioscopy disclosed that the spiral metal sound rested in the usual curved line along the bottom of the stomach, but below it there was evidently a cavity, 8 cm. in height, casting a lighter shadow, and at its base could be seen the familiar lake of fluid contents. The sound could not be pushed down into this cavity until a soft sound was substituted. The history of the noises in the stomach during digestion and the occasional cramps harmonized with the assumption of hourglass stomach. The autopsy showed a marked constriction by a fibrous band, which filled up the groove it made.

32. **Milky Ascites.**—The milkiness can not be ascribed to lecithin as this may be found in the clear fluid as well, Christen finds, contrary to what some have asserted.

33. **Influence of Oxygen in Ether-Glycosuria.**—Seelig announces that in his tests on dogs, ether invariably induced glycosuria during the inhalation and also for three or four hours afterward. The proportion was 8 to 10 per cent. in the more vigorous animals. He also found that with the simultaneous intravenous infusion of oxygen, there was no glycosuria. He is now studying this interesting fact to determine whether the same measure will abolish or prevent glycosuria from other causes.

35. **Tardy Brain Affections After Injuries of Skull.**—Stadelmann relates the details of several cases to emphasize the necessity of long oversight of patients who have suffered some traumatism affecting the head. Exertion of all kinds and the resumption of the occupation should be forbidden. He now makes a practice of keeping such patients in bed for four weeks after any concussion of the brain, and not dismissing them from medical supervision until six weeks have elapsed. In one of the cases he reports the slight fracture of the skull healed with only an insignificant inflammation and circumscribed adhesion of the dura to the bone, and yet seven weeks after the accident symptoms of meningitis developed, proving rapidly fatal. The subject had been able to continue at work during the interim, after the first few days. The meningitis was caused by the pneumo- and staphylococcus. In another case a man received a severe blow on the right parietal lobe, felling him unconscious. He quickly recovered, and was apparently quite well, with no injury to the bone, for four weeks, when he developed typical Jacksonian epilepsy. The autopsy showed disturbances in the circulation at the point of the injury and directly opposite, with softening of the brain tissue and serious hemorrhage later.

42. **Subconjunctival Injections.**—Wessely describes the effect of subconjunctival injections as a local revulsion. They have a reflex action on the vessels inducing hyperemia and its consequences, and attract the protecting substances in the serum to the eye. They are, therefore, important aids in torpid processes, but are directly injurious in acute inflammatory lesions.

47. **Cause and Specific Treatment of Hay Fever.**—Dunbar is the American-German in charge of the Institute of Hygiene at Hamburg. He announces that the specific causal agent of hay fever is the pollen of certain grains which affects the predisposed while harmless for other persons. He has succeeded in reproducing the disease in winter by subcutaneous injection of a minute amount of the toxic substance in the pollen. This toxic substance is not the ethereal oily constituents of the grain, but seems to be an albuminoid body contained in the starch particles. He describes the intense typical attack induced by this procedure in hay fever patients in midwinter while the control subjects did not manifest the slightest reaction to it. He then attempted to produce an antitoxin by inoculating animals with the pollen toxin. For several months the serum of the animals not only failed to neutralize the toxin *in vitro*, but aggravated the symptoms when injected into hay fever patients. But gradually the serum acquired antitoxic power. In the course of his tests he had inoculated 8 hay fever patients in January by instilling into one eye ground corn pollen grains in a centrifugalized aqueous suspension. In every case, without exception, the subjective and objective symptoms of hay fever were produced in varying intensity, while none of the 11 control subjects displayed the slightest objective reaction, even on repetition of the dose and with twenty times the concentration and amount. In the tests of the new serum he instilled into the other eye of the same hay fever patients, the same amount of pollen toxin as before, but mixed with the antitoxin. The eye itched slightly and appeared slightly congested, but all traces of the congestion and itching had vanished by the end of half an hour. In other tests he instilled a drop of concentrated pollen toxin in the eye of a hay fever patient. As soon as the caruncle became congested and the parts smarted he instilled four drops of the antitoxin in the course of twenty minutes. The result was the complete neutralization of the effects of the pollen toxin. The same results, only more striking, were obtained in the nose. He used the pollen from corn in his tests but found that the serum was just as effective against pollen toxin from rye in tests *in vitro* and on the one hay fever subject. He thinks that the pollen toxin of the different grasses and grains is probably identical. The comprehensive report of his researches has been published in book form by R. Oldenbourg, Munich, 1903.

48. **Physiology of Nutrition of Fetus.**—Veit argues to prove that the fetus is nourished by the albuminoid substances in the maternal serum. A syncytiolysin is formed as a side chain of the erythrocytes and a hemolysin as a side chain of the chorionic epithelium. In this way hemoglobin is liberated from the erythrocytes and protoplasm from the deported chorionic villi. The dissolved albuminoid substances flow slowly toward the fetal circulation in the maternal blood, but those substances which are precipitated by the fetal serum do not enter the fetal circulation, and those which are precipitated by the maternal serum do not enter the maternal circulation. The fetus is nourished, therefore, by taking up the albuminoids circulating dissolved in the maternal blood, while the deported chorionic villi are dissolved in the maternal serum. The albuminoids derived originally from the fetus may return to it for its nourishment in this way. This balance may be disturbed by exaggerated deportation of villi which entails exaggerated hemolysis, hemoglobinuria, albuminuria, and weaker syncytiolysis, or by the reverse condition, insufficient deportation of villi. In the latter case the maternal organism does not suffer so much, but the nourishment of the fetus is, perhaps, not so good. The anatomy of the pregnant uterus is, therefore, the key to the question whether there is a defective "Anlage," inflammation, or any cause that may induce an exaggeration or insufficiency of the normal deportation of villi. He appeals for further research in this line, and urges that broad points of view should be adopted and trivial contradictions between the results of single investigators should be overlooked in the search for the underlying principles.

50. **Diagnostic Value of Tuberculin in Keratitis Parenchymatosa.**—Enslin remarks that in an already inflammed eye we can not expect a decisive local reaction to an injection of tuberculin. The characteristic of the general reaction to Old Tuberculin in case of a tuberculous affection is the steep rise and steep decline of the temperature, which commences to be apparent in ten to twelve hours after the injection. This reaction was marked in all his cases in which the keratitis was of tuberculous origin, whether accompanied by lues or not, but it did not occur in any case of syphilis only. In the eight cases of associated tuberculosis and lues this temperature reaction occurred in two after .1 mg. of the Old Tuberculin; in five after injection of 1 mg.; in one after injection of 3 mg. The height to which the temperature rises is less important for the diagnosis than the typical steep peak in the curve, subsiding to the previous temperature within twenty-four hours. The absence of the general reaction speaks in favor of the syphilitic nature of the keratitis, and the steep peak of the temperature curve for its tuberculous nature. In leprosy and actinomycosis the rise is more gradual and lasts longer.

51. **Myosarcoma of Stomach.**—Moser reports from Frankfort what he claims to be the first successful operation on a myosarcoma of the stomach. He also describes a similar case operated on at Greifswald, which terminated fatally Three other cases are on record of extensive resection of the stomach wall for myoma, with one recovery, but in the latter case the tumor was found to have a sarcomatous center. In the personal case described the stomach appeared to be normal in size and outline and the tumor was supposed to originate in the kidney or suprarenal, although the urine was normal. It was reached by a lumbar incision according to Bardenheuer, and found to be in the posterior wall of the stomach, with the normal pancreas closely adherent, requiring resection of the latter; the excised portion measuring 14 cm. and the tumor itself weighing about 1,500 gm. The defect in the stomach wall required 26 Lembert sutures, with a second tier of 32 sutures. Silk was used. The cavity was then rinsed with warm solution of boric acid and tamponed. The operation was done by Pernice and lasted two hours. The patient made a smooth recovery. She was a iipara of 41, and has had no stomach symptoms since, but previously had had occasional pains since her twentieth year, with eructations and bad taste in her mouth. No signs of a tumor had been noticed until shortly

before the operation. The lumbar incision was carried as far up as needed, and a hard bolster placed under the body, which rendered possible the access to the upper portion of the cardia, a region hitherto considered inaccessible. The mistake in the diagnosis unmistakably facilitated the operation.

58. **Reform in Infant Clothing.**—Assmus has been testing a number of substances to supplant the customary diapers for infants. He is much pleased with the results obtained by using an extremely absorbable material in a bag, with a double thickness of mull between it and the skin of the child. This absorbable cushion sucks up all the fluid in urine and feces at once and the child is dry all the time, requiring no changing except at morning and night except after defecation. As all the fluid in the feces is absorbed at once by the cushion, they do not spread and escape as with ordinary diapers. The cushion has also deodorizing properties, so that there is no smell of urine about the child nor in the room from diapers hung out to dry. When the child is taken up its garments and bed are always dry. The soft cushion fits and adapts itself comfortably to the child's body. The substance which fulfills all these conditions is bog moss (Moostorf), which has an absorbing capacity to sixteen times its own bulk. The experiences with it to date have been extremely satisfactory and it certainly realizes a great improvement and saving of expense in the care of the children of the poor. The moss and bags, etc., are supplied by the Berlin firm of E. Cohn Reisner, Neue Friedrichstrasse 65. Berlin C.

60. **Antitoxin Treatment of Tetanus.**—Schuckmann reports a case that terminated fatally the day after a second injection of Behring's antitoxin. He reviews the published statistics and remarks that the best method of administering it can be deduced from the following figures. In twenty cases the antitoxin was injected into the brain, with 25 per cent. recoveries; in three into the veins, with 33 per cent. recoveries; in forty-three the injections were subcutaneous, with 51 per cent. recoveries, and in ten the injections were subdural, after lumbar puncture, with 80 per cent. recoveries. In fourteen cases treated without serum the proportion of recoveries was 57 per cent., and in seventy-six cases treated with serum it was only 47 per cent. He does not believe that the serum treatment is of any appreciable advantage in cases of tetanus

71. **Elimination of Iron in Health and Disease.**—Bartoletti's long article on this subject establishes that subcutaneous injection of iron in health causes an increase for the first few days in the amount eliminated in the urine. As a general rule he found that the proportion was 2.89 to 2.14 on a mixed diet and 5.19 on a meat diet, but the quantity of urine voided during the twenty-four hours must always be taken into account. The amount eliminated in leukemia is not appreciably less than that in health, reaching the minimum of the latter. In chloroanemia the proportion is much reduced. There does not seem to be any regular proportion between the amount of iron in the blood and the amount eliminated, even in the same individual. The decrease in the proportion of iron in the blood in leukemia and chloroanemia is not proportional to the decrease in hemoglobin. In short, he concludes that the laws regulating the elimination of iron are still totally unknown. The variations may be due to differences in the functional capacity of the kidneys.

77. **Slight Value of Cytodiagnosis.**—Concetti has been making an extensive study of the cerebrospinal fluid as a means of diagnosing meningitis in children. He finds that the predominance of lymphocytes is the expression of an irritation of the meninges of toxic origin, while the predominance of polynuclear cells and of the large mononuclears is the expression of a bacterial irritation. The polynuclear and large mononuclear cells gather to repel the invading bacteria by their phagocytic action. Cytodiagnosis thus has not the differentiating value ascribed to it by Widal and others. The formula changes as the irritation is toxic or bacterial, irrespective of the nature of the toxins or bacteria in question.

78. **Influence of Tetragonus on Tuberculous Processes.**—Michelazzi was able to protect guinea-pigs against tuberculosis

by a previous injection of cultures of the micrococcus tetragonus. On the other hand, the tuberculous process was favored when the tetragonus injection was made after tuberculous infection had been realized. He found that the lesions produced by the tetragonus alone in guinea-pigs were identical in every respect with those produced by the tubercle bacilli. Many supposed tuberculous lesions in the human lung are undoubtedly the work of the tetragonus.

79. **Effects of Temporary Ischemia of Thyroid Apparatus.**—Pinto reports that ischemia for sixteen to thirty-one hours induced parathyroid tetany in the numerous dogs in his tests. If the ischemia was maintained for more than thirty-one hours, the animals exhibited mixed phenomena or pure parathyropriva cachexia. The organs were apparently sound in the animals subjected to ischemia for twelve hours or less, when examined a month later, but those with ischemia for sixteen hours to twenty-two days still showed signs of slight alterations.

80. **Suprarenal Glycosuria.**—Barba relates his experience with three patients treated by injections of suprarenal extract. The effects were an aggravation of the general condition in a case of Addison's disease. One of the other patients was in an early stage of tabes and the other had chronic bulbar paralysis. The general health was improved in these cases and diuresis increased. No glycosuria was induced in any instance, nor in tests on healthy subjects.

84. **Effects of Excision of Medullary Substance of Suprarenal Capsules.**—Rabbits and cats died in rapidly progressive cachexia after extraction of most of the medullary substance. Partial excision did not produce any appreciable symptoms.

86. **Tabes and Aortitis.**—Arullani has observed that lesions of the aorta are very common in tabes. When a valvular affection develops in the course of tabes it is almost certain to be aortic insufficiency from dilatation of the aorta. This is due to the action of syphilis, alcohol, lead or some other intoxication.

88. **Agglutination by Tubercle Bacilli.**—Ilvento's experience has confirmed the fact that the serum and pleural effusion of tuberculous subjects are able to agglutinate the bacilli. It not only serves as a diagnostic measure but affords insight into the relative immunity of the organism in question.

95. **Traumatic Dropsy.**—The patient was a woman of 29, previously healthy, who fell into the water. In consequence, undoubtedly, of the fright and the cold, general dropsy developed.

96. **Strong Bactericidal Action of Epileptic Serum.**—Tirelli has found that the serum of epileptics is much more bactericidal than ordinary serum. It is especially active against staphylococci, and he suggests that it might be possible to utilize it to induce immunity against and also to cure staphylococcus infection. He ascribes to this peculiarity of the serum the rarity of suppurative lesions in epileptics.

100. **Liquefaction of Gelatin as Test of Canned Meats.**—Grixoni proclaims that when the gelatine in canned meats is liquified at a temperature below 64.5 F. it can be attributed to the action of living bacteria and their ferments. The meat should be considered spoiled, although it may not exhibit any other evidence of putrefaction except a splashing sound when the can is shaken.

101. **Linitis Plastica.**—The four cases described presented the clinical picture of plastic linitis, but histologic examination disclosed diffuse carcinomatous degeneration.

102. **Coagulability of Blood in Phosphorus Intoxication.**—The coagulating power of the blood was quite abolished after five days of subacute phosphorus intoxication in the tests on animals described in this communication.

104. **Resection of Intestine.**—Fantino remarks that the cases most favorable for extensive resection of intestine are those with hypertrophy of the sound portion. The first or second part of the small intestine is the best portion for such an operation. In one of the two cases he reports he failed to recognize the part of the intestine involved, and, under a mistaken impression, resected the entire colon and three feet of the small intestine. The patient survived nine months in comparatively good condition. The anastomosis was made under the same incorrect impression, and the food passing through the intestines had to travel a very roundabout route. This kept it longer in the intestines and gave more time for digestion, and to this fact he ascribes the unexpectedly favorable results secured. He suggests that the disadvantages of extensive resection of the intestine might be counteracted by modifying the technic so as to compel the ingesta to follow a circuitous route and thus have as good opportunity for digestion as under normal conditions.

106. **Hernia of Bladder.**—If the bladder alone is involved in the hernia the sac will be soft and flabby when empty and distended when full of urine. Its size also alters with change of position, coughing, etc. Pressure on it induces a desire to urinate. When the bowel is also involved besides the part with the above characteristics, the sac has a second usually the outer part, which has the characteristics of an intestinal hernia. The catheter may be passed through the urine into the sac or may aid in the diagnosis by withdrawing urine from it. After the subject has spontaneously voided his urine, an additional portion may be emitted on compression of the tumor. There may be pain in the kidney region on the side of the hernia. Resection is inadvisable unless the communication with the bladder is extremely small.

107. **Percussion of Spleen in Infants.**—If the child is held by a third person so that the spleen is at the lowest position possible, in the back, percussion applied from below, on the back, will avoid interference from other organs and afford more information than is obtainable in any other way. The child is held in a position that is neither on its back nor on its left side, but between these.

108. **Acetonuria.**—Satta investigated the influence of ingestion of fats on the elimination of acetone in ten diabetics. He found that 12 to 15 gm. of butter increased the acetone by a gram in the severer cases, but in the mild ones it had little influence. Olive oil and beef fat had a similar effect, but less pronounced.

112. **Chronic Splenomegalia with Anemia and Myelemia.**—Study of the blood shows that splenic anemia comprises lymphogenic leukemia and myelogenic leukemia in nurslings as well as in adults. The prognosis is grave, but not inevitably fatal in the infantile form. Treatment to date has not given very encouraging results. Iron and arsenic are the main reliance, but Combes has reported good results from administration of bone marrow, and Pietro of the extract of fresh spleens.

121. **Sterilized Linen for Infants.**—This communication from Lyons states that during the last few months the diapers and garments used for the infants in the hospital have been sterilized in the same way as the dressings, etc., for surgery. The outfit for each babe is wrapped in a separate cloth, arranged in order and then sterilized and handled as little as possible. The attendants disinfect their hands as for assisting at an operation before taking up the babe. They find that the extra trouble is more than compensated by the prevention of cutaneous affections and the rapid healing of those observed when the infant is first received. This method of aseptic care of infants has been found to pay in the saving of both time and trouble in the end, beside the advantages for the child.

125. **Hot Springs in Uterine Affections.**—Blondel proclaims that, aside from the acutely inflammatory and painful stage and from absolutely irreducible lesions and tumors, a course of hot mineral springs waters may be found beneficial at any phase of a uterine affection. The menstrual period is no contraindication, on the contrary, the system is in a peculiarly favorable receptive condition at such times. The "thermal cure," as the French call a course of treatment at the hot springs, is particularly beneficial in the leucorrhea of anemic subjects, in congestion of the uterus in arthritics, in chronic parametritis, in physiologic menstrual troubles, and in uncomplicated ovarian pains, also in cases of chronic and rebellious vaginal discharges in herpetic and arthritic women. After the thorough working over of the soil, therapeutics is more effective, and instead of waiting to advise the waters as a last resort, he advises prompt resort to them as a most valuable adjuvant in uterine affections.

126. **Medical Treatment of Anal Fistulas.**—De Vevey reports five cases of anal fistula in which surgical intervention was impracticable, and in which he succeeded in curing the patients in the course of six to eight months by repeated injections of a 2 to 2.5 per cent. solution of copper acetate. He irrigated the parts three times a week with this solution, applying it on a compress in the interim, and insisting on the patient's reclining. He also gave internally guaiacol and small doses of dilute copper acetate.

129. **Flushing the Intestines in Dysentery.**—Belleli practices at Port Said and has found injections of a liter of tepid water to which 20 to 40 drops of carbolic acid have been added, so useful in dysentery that he is inclined to regard them as almost a specific for this disease. The colics and flatulence subside and the recurring exacerbations are less frequent and less painful. If the buttocks are raised 25 to 30 cm. above the level of the head, the water flows into the transverse colon without the need of any special apparatus. It is then rapidly voided. In chronic dysentery there is usually recurrence of the painful spasmodic attacks every fifteen to thirty days. It is probably due to some peculiarity in the life cycle of the amebæ, and can be prevented, or at least modified, by giving the injections in a mucilaginous vehicle and adding an astringent. He has found the following combination useful: 50 to 60 gm. of althea in 2 liters of water, with 3 to 5 gm. of tannin and 30 to 40 drops of carbolic acid. It is wise to vary the astringent at times, substituting 2.5 to 4 gm. of alumnol to the 2 liters of water. This enteroclysis must be accompanied by the administration at the same time by the mouth of 2 or 3 gm. of bismuth salicylate a day, to soothe the erethism of the gastrointestinal tract. The salicylate may be alternated with dermatol, tannigen or vaccinum myrtillus. He gives the latter in a decoction. Opium should be strictly avoided.

131. **Antistaphylococcus Serum.**—Doyen complains that little attention has been paid to his announcement of the success of the serum he has produced by means of inoculation of animals with the *Staphylococcus aureus*. It has proved more powerful and more constant in its effects than any other serum yet known in experiences with hundreds of cases. At the early stages of a furuncle or abscess a single injection of 5 c.c. is usually sufficient. The pain and tension cease in two or three hours and the lesion is aborted. In a large carbuncle complicated by diffuse phlegmon, the elimination of the necrosed portions proceeds so rapidly under the influence of the serum that in six to eight days nothing remains of the lesion except a small red granulating surface. The serum was applied in a case of severe phlebitis of the ophthalmic vein and cavernous sinus, with bilateral ophthalmia and delirium. The patient recovered, although the infection had been so severe that the sight of one eye was lost. The improvement was rapid in a case of phlebitis of the cavernous sinus consecutive to a carbuncle on the temple, the patient already in coma. The sore throats and other lesions due to the staphylococcus yield to the serum with equal promptness, but it has no influence on streptococcus infections. One of its most promising applications is in simultaneous injection with antitetanus serum in cases of complicated fractures, extensive contusions and soiled wounds. In a recent case of this kind, a complicated fracture of both legs in a railroad accident, in which amputation seemed inevitable, under this combined serum treatment the patient made a smooth recovery and his legs were saved.

132. **Treatment of Gout.**—Debove warns that gouty subjects are the most difficult patients to handle. They have notions of their own in regard to medicines and argue with the physician at every step. On the other hand, they are extremely credulous as far as quacks are concerned. He remarks that morphin is the most admirable of all remedies in the treatment of the accidents of acute, painful gout, while it is the most deplorable of all in the chronic form.

New Patents.

Patents of interest to physicians, March 3 and 10:

The Public Service.

Army Changes.

Movements of officers of the Medical Department, U. S. Army, under orders from the Adjutant-General's Office, Washington, D. C., from March 7 to 21, 1903:

DeWitt, Wallace, first lieut. and asst.-surgeon, is relieved from further attendance at the Army Medical School, Washington, D. C., and will proceed to Fort McPherson for treatment and observation by the post surgeon.

McAdory, Robert J., contract surgeon, U. S. A., is relieved from duty at Camp McKinley, H. I., and will proceed to San Francisco, and report by telegraph to the Adjutant-General of the Army for further orders.

A board of officers, to consist of Col. Calvin DeWitt, assistant surgeon general, Major Louis A. LaGarde, surgeon, Major Henry P. Birmingham, surgeon, Major James D. Glennan, surgeon, and Capt. Carl R. Darnall, asst.-surgeon, has been appointed to meet at the Army Medical Museum Building, in this city, on Wednesday, April 15, 1903, at 10 o'clock a. m., for the examination of candidates for admission to the Medical Corps of the Army. The board will be governed in its proceedings by such instructions as may be communicated to it by the Surgeon-General of the Army.

Navy Changes.

Changes in the Medical Corps of the Navy for the week ending March 21:

A. A. Surgeon A. W. Kaines, appointment revoked, to take effect on reporting of relief.

P. A. Surgeon F. L. Benton, ordered to the Naval Station, Cavite, P. I.

Surgeon G. A. Lung, detached from the Bureau of Medicine and Surgery and ordered to the Naval Hospital, Philadelphia.

Asst.-Surgeon J. Stepp, detached from the *Isla de Luzon* and ordered home to wait orders.

A. A. Surgeon P. L. Cooke, ordered to the Naval Academy, Annapolis, Md.

Surgeon F. A. Hesler, died March 11 on board U. S. S. *Wilmington*, en route from Cavite, P. I., to Yokohama, Japan.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended March 19, 1903:

Assistant Surgeon-General L. L. Williams, to proceed to New York City, as inspector of the Purveying Depot.

P. A. Surgeon H. W. Wickes, relieved from duty at Cincinnati, and directed to proceed to Reedy Island Quarantine and assume command of the service at that port, relieving Asst.-Surgeon T. F. Richardson.

Asst.-Surgeon C. E. Decker, granted extension of leave of absence, on account of sickness, for fourteen days from March 7.

Asst.-Surgeon H. C. Russell, to proceed to New York and report to Surgeon G. W. Stoner, Immigration Depot, for temporary duty.

Asst.-Surgeon L. D. Fricks, on being relieved from duty at Cape Fear Quarantine, to proceed to New York and report to Surgeon G. W. Stoner, Immigration Depot, for duty.

Asst.-Surgeon J. W. Kerr, relieved from duty at New Orleans, and directed to proceed to Cincinnati and assume temporary command of the service at that port.

Asst.-Surgeon T. F. Richardson, on being relieved from duty at Reedy Island Quarantine by P. A. Surgeon H. W. Wickes, to report to him for temporary duty; on expiration of said temporary duty to proceed to New Orleans and report to medical officer in command for duty and assignment to quarters.

Asst.-Surgeon W. A. Korn, to report to medical officer in command at Philadelphia, for assignment to special duty.

Asst.-Surgeon J. W. Schereschewsky, relieved from duty at New Orleans, and directed to report to Surgeon G. W. Stoner, Immigration Depot, New York, for duty.

Asst.-Surgeon M. W. Glover, relieved from duty at the Immigration Depot, New York, and directed to proceed to Baltimore, and report to medical officer in command for assignment to special duty.

Asst.-Surgeon B. S. Warren, on expiration of leave of absence, relieved from duty at Washington, D. C., and directed to proceed to Cape Fear Quarantine, relieving Asst.-Surgeon L. D. Fricks, and assume command of the service at that port.

Asst.-Surgeon A. M. Stimson, relieved from duty at the Immigration Depot, New York, and directed to proceed to New Orleans, and report to medical officer in command for assignment to special duty.

A. A. Surgeon Fernando Aleman, granted leave of absence for seven days from March 8, 1903, under provisions of Paragraph 191 of the regulations.

A. A. Surgeon W. E. Patrie, granted extension of leave of absence for seven days from March 13.

Pharmacist R. H. Gibson, granted leave of absence for twenty-three days from March 9. Relieved from duty at the Gulf Quarantine Station, and directed to proceed to Vineyard Haven, Mass., and report to medical officer in command for duty and assignment to quarters, relieving Pharmacist L. P. Hall.

Pharmacist F. L. Brown, on being relieved from duty at Cape Charles Quarantine, to proceed to Pittsburg, Pa., and report to medical officer in command for duty.

Pharmacist C. W. Stephenson, to report to chairman of board of examiners at Chicago, for the purpose of determining his fitness for promotion to the grade of pharmacist of the second class.

Pharmacist L. P. Hall, on being relieved from duty at Vineyard Haven, Mass., to proceed to Cape Charles Quarantine and report to medical officer in command for duty and assignment to quarters, relieving Pharmacist F. L. Brown.

Pharmacist L. C. Spangler granted leave of absence for twenty-five days from March 4.

BOARD CONVENED.

Board convened at Chicago, March 31, 1903, for the purpose of examining C. W. Stephenson, pharmacist of the third class, to determine his fitness for promotion to the grade of pharmacist of the second class. Detail for the board: Surgeon C. E. Banks, chairman; Asst.-Surgeon L. P. H. Bahrenburg, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended March 21, 1903:

SMALLPOX—UNITED STATES.

Alabama: Mobile, March 7-14, 4 cases.
California: Berkeley, March 4-11, 1 case; Los Angeles, Feb. 28-March 7, 5 cases; Sacramento, Feb. 28-March 7, 1 case; San Francisco, March 1-8, 8 cases.
Colorado: Denver, Feb. 28-March 7, 17 cases.
District of Columbia: Washington, March 7-14, 2 cases.
Illinois: Chicago, March 7-14, 8 cases, 2 deaths.
Indiana: Elwood, March 8-15, 1 case; Evansville, March 7-14, 2 cases.
Iowa: March 7-14, Davenport, 8 cases; Dubuque, 1 case.
Kansas: Douglas County, Feb. 1-28, 1 case.
Maine: Biddeford, Feb. 28-March 14, 8 cases.
Maryland: Baltimore, March 7-14, 5 cases.
Massachusetts: Boston, March 7-14, 1 case; Fall River, March 7-14, 3 cases; New Bedford, March 6-14, 2 cases.
Michigan: Detroit, March 7-14, 17 cases; Grand Rapids, Feb. 28-March 14, 24 cases, 1 death; Port Huron, March 7-14, 3 cases.
Missouri: St. Louis, March 8-15, 4 cases.
Nebraska: Omaha, March 7-14, 2 cases.
New Hampshire: Manchester, Feb. 28-March 14, 16 cases.
New Jersey: Camden, March 7-14, 1 case; Jersey City, March 8-15, 3 cases; Newark, March 7-14, 1 case.
New York: March 7-14, Buffalo, 2 cases; New York, 2 cases.
Ohio: Cincinnati, March 6-13, 10 cases; Cleveland, March 7-14, 1 case; Dayton, March 7-14, 7 cases, 2 deaths.
Pennsylvania: March 7-14, Altoona, 1 case; Philadelphia, 44 cases, 5 deaths; Pittsburg, 48 cases, 2 deaths.
South Carolina: Charleston, March 7-14, 3 cases; Greenville, Feb. 28-March 7, 2 cases.
Tennessee: Johnson City, Feb. 28-March 7, 14 cases; Memphis, March 7-14, 2 cases; Nashville, March 7-14, 1 case.
Washington: Colfax, March 1, present.
Wisconsin: Green Bay, March 8-15, 3 cases; Milwaukee, March 7-14, 2 cases.

SMALLPOX—INSULAR.

Philippine Islands: Manila, Jan. 3, 2 cases.

SMALLPOX—FOREIGN.

Austria: Prague, Feb. 14-28, 20 cases.
Belgium: Brussels, Feb. 14-28, 9 deaths.
Brazil: Pernambuco, Jan. 15-31, 10 cases; Rio de Janeiro, Feb. 5-12, 8 deaths.
Canada: St. John, N. B., March 13, 1 case.
Chile: Antofagasta, Jan. 1-31, 13 deaths.
Ecuador: Guayaquil, Feb. 7-21, 1 death.
France: Rheims, Feb. 8-15, 2 cases; Reubaix, Feb. 1-28, 6 deaths.
Great Britain: Birmingham, Feb. 21-28, 11 cases; Cardiff, Jan. 25-31, 1 case; Glasgow, Feb. 27-March 6, 1 death; Leeds, Feb. 21-28, 9 cases; Liverpool, to Feb. 28, 60 cases, 7 deaths; Nottingham, Feb. 14-21, 4 cases; Sheffield, Feb. 28-March 7, 2 cases.
India: Bombay, Feb. 10-17, 36 deaths; Calcutta, Feb. 7-14, 2 deaths; Karachi, Feb. 8-15, 1 case; Madras, Jan. 31-Feb. 6, 1 death.
Italy: Palermo, Feb. 21-28, 5 cases.
Mexico: City of Mexico, Feb. 22-March 1, 7 cases, 4 deaths; Vera Cruz, Feb. 28-March 7, 1 case.
Russia: Moscow, Feb. 7-21, 11 cases, 2 deaths; Odessa, Feb. 14-28, 4 deaths; St. Petersburg, Feb. 14-28, 100 cases, 9 deaths.
Straits Settlements: Singapore, Jan. 17-31, 10 deaths.

YELLOW FEVER.

Brazil: Rio de Janeiro, Feb. 5-12, 40 deaths.
Colombia: Panama, Feb. 26-March 5, 2 cases, 1 death.
Mexico: Vera Cruz, Feb. 28-March 14, 7 cases, 4 deaths.

CHOLERA—INSULAR.

Philippine Islands: Manila, Dec. 27-Jan. 31, 6 cases, 4 deaths; Provinces, Dec. 27-Jan. 31, 1,985 cases, 1,436 deaths.

PLAGUE—INSULAR.

Philippine Islands: Manila, Dec. 27-Jan. 3, 3 deaths.

PLAGUE—FOREIGN.

India: Bombay, Feb. 10-17, 888 deaths; Calcutta, Feb. 7-14, 171 deaths; Karachi, Feb. 8-15, 23 cases, 19 deaths.
Mexico: Mazatlan, to March 13, 313 cases, 255 deaths; Oso, to Feb. 15, 1 case.

Addresses.

THE STUDY OF PEDIATRICS IN ITS RELATION TO MEDICAL EDUCATION.*

THOMAS MORGAN ROTCH, A.B., M.D.

PROFESSOR OF PEDIATRICS, HARVARD UNIVERSITY.

BOSTON.

As our knowledge of the various branches of medicine increases through the great advances which are being made in the methods of scientific research, it becomes more apparent that every branch of medicine has been more or less imperfectly studied by and taught to the student of medicine before he enters on his life's work. It is therefore necessary almost every year to pay especial attention to broadening and perfecting the medical curriculum of our university teaching. What is true of one branch of medicine, holds also with the others, and I shall speak to you to-night on the subject of pediatrics, merely because I happen to represent this department in one of our eastern universities, Harvard. In no way do we so well acquire experience in, and add to our knowledge of, a subject as by attempting to teach it and by being brought into close contact with the active minds of young men in their early twenties, especially when, as is the case at Harvard, all of them are graduates from recognized universities and hold an A.B. or an equivalent degree. In no way are we so greatly stimulated to add, year by year, to our knowledge of the subject which we are attempting to teach as by being met year by year by a new set of these young men.

It is for this reason that I enter, with a great deal of enthusiasm, into the description of the methods which we have adopted in teaching at Harvard and the ideals which we hope in the future to attain. I happen to have had a somewhat extended opportunity for teaching the subject of pediatrics, and the development of this branch of medicine, having been connected with the teaching body of Harvard University for the past twenty-five years. I have seen the teaching of pediatrics from the time that it existed only in the department of general medicine and when it was taught only in a few lectures, given by the professor of the theory and practice of medicine, these lectures being interspersed in his teaching of the medicine of adult life. I have seen the beginning of separate teaching of children alone, represented by a class of half a dozen students, once or twice a week for half of the medical year. I have seen the subject of pediatrics then become an elective with the students, so that they had to choose between gynecology and pediatrics. I have then seen the class increase from one-half its numbers to the entire class, through the establishment of a separate department for pediatrics, with its required examination for a degree, and the teaching first placed in the hands of an instructor, then of an assistant professor in the faculty, and finally of a professor of pediatrics, the subject thus becoming a recognized department, on a par with the older and more established subjects representing the various departmental divisions of the Harvard faculty.

It is rather remarkable, from a pedagogic point of view, that the special study of children has not only for so long a time and in so many universities held such a minor position, but also that it has been so difficult to attain proper recognition for this important department of medicine without unceasing vigilance and arduous work, not only in promoting the scientific side of the subject and thus improving the teaching, but most of all in contending against the opposition to its recognition by the older and established departments with their endowed professorships. Such, however, is the case, and if we look over the principal centers of medical teaching in this country it will be seen how true it is that in almost every case an insufficient amount of teaching, as to time, is given to the medicine of early life, how inadequate are the opportunities for this teaching in the various schools, and often how lacking is the knowledge which the teachers themselves have of the subject. This, in many cases, is owing to pediatrics having been taught by men who, as experts in other branches, have a reputation, but who, evidently, have had but a small amount of instruction themselves in this branch. Thus we have seen and will at times see the teaching of children a part of the course on obstetrics or on gynecology, or, as is usually the case, in the province of general medicine. There is no doubt that it is in general medicine that the teaching in regard to children is best placed from a theoretical standpoint.

We have heard it said that under one head there could be a department devoted to the clinical medicine of all ages. If, however, we appreciate the number of hours which it is necessary to devote to the clinical pathology and symptomatology of adult life, and believe that an equal number of hours and the same opportunities for acquiring the knowledge of the pathology and symptomatology of early life are necessary, it is evident that it would simply be impossible practically to have one professor do justice to such a broad range of clinical medicine, in fact, such a professor would have to be a man of such education and such mental caliber that it would be exceedingly rare to find him in any part of the world. The number of hours in the day would have to be doubled if one man should devote his time to teaching all branches of clinical medicine, and many hospital

* An address delivered by request of the Chicago Pediatric Society, at a joint meeting of that society and the Chicago Medical Society.

services would necessarily have to be taken in order to keep properly abreast of the advances which are being made in the different branches. Again, such broad subjects as neurology, obstetrics and gynecology may, in the same way, be classed under the head of general medicine. The term "professor of clinical medicine" in our universities is evidently a misnomer, as there is a clinical medicine of so many branches that, as I have just stated, it would be impossible to have these branches well covered by one man, even if such a man simply superintended the teaching of them. Such methods would be very unsatisfactory, and he would continually find that, unless he could have time and opportunity for teaching in the various hospitals devoted to the especial branches, he would inevitably fail to keep abreast with those who were studying these branches in especial hospitals and who would soon fail to recognize him as their chief. It has become very evident, therefore, that a number of subdivisions of general clinical medicine must not only be recognized in the teaching curriculum of any advanced medical school, but that it must be insisted on that the teaching of these various divisions should be fostered in the special hospitals where the greatest opportunities are given for the study of them, and that physicians should be appointed to these hospitals who not only will best serve the patients, but will also, from their general education, personal enthusiasm and capabilities, best impart to the student of medicine the practical knowledge of diagnosis and common sense treatment, which can only be obtained in this way.

It is often asked wherein the diseases of children differ from the diseases of adults, and much skepticism as to such difference exists in the minds of those who have had little opportunity for studying clinical medicine, both in the large general hospitals devoted to adults and in the hospitals devoted to the early periods of life. The fact is that, with very few exceptions, there are no diseases of children; diseases *of* children is a misnomer; what we have to deal with is a manifestation of diseases as they occur *in* children. The disease, or, rather, the cause of the disease, is the same, whether it be in later or earlier life. It is the differences that occur in these diseases, according to the period of life when they are studied, that makes so very difficult the teaching of the pathology, symptoms, diagnosis and treatment of old age, of fully developed adults, of adolescence, of children in the early period of childhood, in the middle period of childhood, of infants in their second year, in the middle or latter part of their first year, in the early months, weeks or days of early life, and of premature infants. If we appreciate the great clinical differences in these periods, great in their extent, broad in their scope, important in their relations, we can not but be forced to a conclusion that a problem quite large enough for one man at present to deal with is presented by the clinical medicine of old age, of fully developed adult life, and of adolescence, and for another of the different periods of childhood and infancy.

So far as the name of the department devoted to the study and teaching of children and infants is concerned, it really makes very little difference under what name we teach, provided that sufficient proportionate time be given to each branch by the men who have the greatest opportunity for studying and improving their knowledge of these periods of life. At Harvard we have decided to use the name pediatrics, a word meaning the hygienic or medical teaching of children. The medical societies devoted to the study of children have adopted this name; the medical journals devoted to the diseases of early life have also assumed this name. We should understand, therefore, that there is a clinical medicine of early life from birth to adolescence.

If we decide that there are no, or few, especial diseases of children, but that our province is to teach clinical medicine according to the age and stage of the development of the patient, the study of pediatrics becomes much simplified. The more, however, that we study the conditions of early life, both in health and in disease, the more are we impressed by the breadth of the subject, and the more are we convinced that a much larger amount of time should be given to it before a student can be expected to intelligently diagnosticate its diseases and practically treat them. At Harvard the subject of pediatrics is taught through the whole third year, and is soon to become a part, also, of the fourth year, when opportunities will be given for advanced teaching. The idea which is at present held with us, is that the best method of teaching, and the one which will be carried out after the new medical school buildings and the hospitals connected with them have been finished, will be somewhat as follows:

In the first place, we recognize that the most thorough and systematic study and treatment of disease at the different periods of life can be best accomplished by having, so far as is possible, these different periods of life taken care of in separate hospitals. Where infants or young children have in the past been treated in connection with adults, it has almost invariably happened that in the hospital management most attention has been paid to the later period of life, at the expense of the earlier. We, therefore, expect to have, in connection with the Harvard Medical School, a children's hospital and an infants' hospital, entirely separate from each other and from the general university hospital for adults. In like manner, we have learned by experience that where it has been attempted to arrange a hospital régime for both children and infants, it is the infants who are most likely to suffer, such a great difference between these two degrees of development exists in the amount of air space needed for the individual, in the requirements for the laundry, in the number of nurses, and lastly in the method and precision of feeding. It has, indeed, been found that much greater advances in the study of and in the care of infants can be obtained by having them under entirely separate hospital management. So far as university medical teaching is concerned, it is as important to treat these different classes of cases in different buildings as it is to have separate laboratories for physiology, bacteriology and chemistry.

It would be impossible in one evening to enumerate all the phases of the different diseases which in early life markedly differ from the manifestation of disease in later life. A slight review, however, of the differences which have been impressed on me as important, and the fact that such differences exist and require much time to teach will perhaps be of interest to you. From the very beginning of my studies in pediatrics I have been impressed with the idea that a knowledge of the anatomic and physiologic conditions which exist in the early periods of life is the keynote to the proper understanding of the diseases of this early period and is of prime importance for its diagnosis and treatment. I might mention as important anatomically, the open petro-squamosal suture which exists and continues to exist in the first two or three years of life, and that

this anatomic condition, in connection with the great proportionate vulnerability of the infant to infection of the middle ear, makes possible a variety of cerebral symptoms which are seldom seen in later life, while at this early period they are very common. These symptoms can only be thoroughly understood and intelligently dealt with when we appreciate the value of this anatomic condition. Again, a knowledge of the greater frequency of adenoid growth at an early period of life, carries with it the explanation of the symptoms of many abnormal conditions which otherwise would fail to be understood unless this tendency to lymphoid growth were recognized. Again, the recognition that in early life the bladder is an abdominal, and not a pelvic organ is of importance to the surgeon, while the greater proportionate length and freedom in motion of the mesentery is of the greatest significance in regard to the intussusceptions, which are so much more common in infants than in the later stages of development. In like manner the greater proportionate length of the sigmoid flexure in early infancy, and the continuation of this condition to a later period becoming an error of development, with its accompanying symptoms connected with rhachitis, illustrates how the diagnosis of many diseases would be very obscure unless these anatomic conditions were recognized. The development of the bones and the different periods of ossification, present to us anatomic facts which are of great aid in the diagnosis of the period at which certain diseases develop, and has, in cardiac diseases, aided us in differentiating congenital from acquired lesions of the heart. I refer to the displacement of the sternum, which, when produced by intrathoracic pressure, takes one or the other form according to the period of ossification of the different parts of the sternum, in relation to the time when the cardiac disease began. A careful study of the various investigations which have been made in the physiologic laboratories, shows that the physiologic conditions which normally occur at different periods in early life are of the utmost importance in connection with the treatment of the diseases which arise at these periods.

It is not only the physiologic investigations in connection with gastric and duodenal digestion which plays so great a rôle in the various disturbances of early life, but also the studies which will in the future be carried to still greater perfection in connection with the unstable nervous system of early life, and the undeveloped conditions of the nervous centers. There is not much doubt, also, that a special study should be made of the pathologic conditions which arise in early life, a knowledge of which is of the greatest aid, not only for the intelligent treatment of the organs affected, but also in the aid which it gives us in determining the prognosis of the especial diseases. The wonderful recuperative power of the kidney in the early periods of life, is an instance of this, and makes the pathologic study of the various forms of nephritis as well as of functional renal diseases extremely interesting and important.

The pathologic conditions connected with the three most important diseases of nutrition which occur in early life, and which have a peculiar significance in the clinical medicine of that period, namely, infantile scorbutus, infantile atrophy and rhachitis, present only a small part of the immense amount of especial study which is needed for these diseases which primarily only occur in early life, but the results of which are found at a much later period of development.

Again, in studying the diseases where there are decided pathologic lesions of special organs we must recognize the varied forms of meningitis or of simple cerebral irritation which occur so much more frequently among infants and young children than in older children and adults. The study of the different organisms which produce so readily and so frequently cerebral symptoms in early life opens up in itself an immense field of investigation, a field which can best be studied in the wards of hospitals devoted to infancy and to childhood. The variety of lesions and of symptoms which occur in the pneumonias of infancy are so great in number that they form a special clinical medicine in themselves. The mixed infections, so much more common in early life than at a later period, illustrate this statement and teach us that a knowledge of the pneumonias of later life are entirely inadequate for the symptoms, diagnosis and prognosis of an earlier period. Again, we may mention the susceptibility of the heat centers in infants and young children to the action of very cold baths and to ice bags applied to the head, by which the vitality of the patient is so frequently lowered as not infrequently to cause collapse, whereas in later life the same treatment might be used with benefit.

The proper appreciation of infantile eclampsia in all its varied forms and with its manifold etiology calls for a study of many years to be fully understood, and shows us that this condition often arises from entirely separate causes from the eclampsias of a later period, in that it so often depends on the anatomic and physiologic conditions as only exist in early life, and which lose their significance at a later period.

Another set of diseases which causes not only many symptoms connected with an early period of development, but also presents the most serious results from its terminal processes in later life, is a certain class of infectious diseases, such as scarlet fever, diphtheria, measles, pertussis, varicella and others which illustrate this statement. In this connection it is extremely interesting to observe the cardiac dilatations secondary to and the cardiac hypertrophy tertiary to scarlet fever. These serious conditions are far more common in infancy and childhood than at a later period, and this class of diseases is so much more frequent in children than in adults that they may almost be called diseases of early life. The rôle which they play is very great, and they should as a class be one of the principal features in the curriculum of the pediatric department, for they belong to it.

The much greater frequency of the diseases of the mouth and of the gastroenteric tract in early life makes a much more extended knowledge of these diseases and special precision in the nomenclature which covers them necessary for those whose province it is to practice principally among children and to teach pediatrics.

This subject of nomenclature is of a good deal more importance than is usually recognized, and the study of pediatrics would be much more simple if such a classification were in vogue in all the universities, even if it were only temporary, as it might be used until some better one could be obtained.

What is especially important is to classify these diseases under some one reasonable nomenclature, so that physicians in the different parts of the world can know in writing on and investigating the diseases of the mouth or of the gastroenteric tract what each one is talking about, and not be at a loss to know if some one else is investigating the same disease under a different name, or, as is especially noticeable in the group of diseases

which is classified under dysentery, calling a number of diseases by one name.

I have thought it worth while to show you the classification which we have temporarily adopted at Harvard in these diseases. This classification of diseases of the mouth in early life is one which was adopted by the pediatric department of Harvard after it had been presented to and endorsed by the American Pediatric Society at its meeting at West Point in 1893, and was prepared by Dr. F. Forchheimer of Cincinnati and myself, who had been appointed by the society in 1892 as a committee to carry out this work.

The infectious diseases of the mouth are so much more frequent in infants than in older individuals that a systematic nomenclature was found to be especially necessary in order that the subject could be taught more systematically and rendered more intelligible to the student. It is not necessary in presenting this nomenclature to explain to you in detail the various facts on which it is founded. The main idea is that there is probably in every disease of the mouth an underlying stomatitis which renders the mucous membrane of the buccal cavity vulnerable to the various organisms which cause its disease.

NOMENCLATURE OF DISEASES OF THE MOUTH.

      - Diphtheria.
      - Tuberculosis.
      - Syphilis and like diseases.
    - Gangrenosa
      - Noma.

The following nomenclature of the diseases of the gastroenteric tract in infancy shows the classification which is now used in the department of pediatrics at Harvard, and is the one which was endorsed by the American Pediatric Society at its meeting in Washington in 1891, when it was presented by a committee appointed by the society to simplify the unnecessary, complicated and irrational names which up to that time had been in vogue throughout the world. This committee consisted of Dr. Emmett Holt of New York and myself. This nomenclature is merely intended to fill temporarily a much-needed demand until a more precise and rational nomenclature can be drawn up on a purely etiologic basis.

At present in the Harvard Medical School pediatrics is taught every day in the week during the entire medical year. Early in the beginning of the course, during the first month or six weeks, I personally give some elementary lectures to the whole class on three broad subjects:

1. On the elementary knowledge required to appreciate scarlet fever, measles, varicella and diphtheria. As soon as this elementary instruction has been concluded the students are sent in sections to the South Department of the Boston City Hospital, where one of my instructors shows them cases of scarlet fever, measles, diphtheria or any other contagious diseases which happen to be in the hospital. This South Department of the City Hospital is a separate hospital in itself, and is one of the best equipped and finest in the world, probably coming second only to the one in Glasgow. The students are here taught the diagnosis and treatment of the diseases, the best methods of disinfection and isolation, intubation and the use of antitoxin. Each student is required to report on two cases which he has seen during the course of this instruction, and this report is submitted to me at the end of the year, and is taken into account in the final examination for the degree.

The close relation between the different diseases which occur in children, both as to the terminal processes caused by these acute infectious diseases, or occurring in connection with these diseases, such as whooping cough and the different forms of pneumonia, is of such great importance to the student to see before entering into practice, that it has been deemed advisable to still further

broaden this course, and we are now contemplating giving advanced teaching in these diseases in the last year of the school course.

2. In like manner I give an elementary course on the gastroenteric diseases of infancy to the whole class just before the clinical teaching of these diseases is given in the wards and out-patient clinics.

3. I have also found that it is necessary to give some preliminary lectures on human breast feeding, and on the general principles of our American percentage feeding, before the practical teaching, both in the classes and in the wards, can be carried out with success.

What I especially wish to explain in regard to what I have just said is, that certain preliminary didactic lectures should be given on the subjects just mentioned before the student is given his bedside instruction.

After these three preliminary divisions have been briefly mapped out for the students, certain didactic lectures are given by myself twice a week to the whole class, such diseases being especially spoken of which it so happens in an especial year can not be obtained for the clinical

exercises. When examples of these diseases can be obtained the didactic teaching is replaced by the clinical, and what I have found to be of especial value in this latter method of instruction is not only the close intercourse with the individual student which it allows, but also the mutual stimulation to criticise and discuss the various features of the case with each other which it engenders, as these exercises are made entirely informal. Certain subjects are also taught from the text-book, but this part of the teaching is very limited, and is soon supplemented by what we are in the habit of calling case teaching. This is usually given at the end of the year, just before the examination, and is a discussion of picked cases, the history of which has been given to the student (printed) in the previous week, so that he may have the opportunity of studying the case before it is discussed. The teaching of the whole class, both didactic, clinical, by recitations and by case teaching, plays, however, but a small part of what we consider the best methods of instruction in the department of pediatrics. The greater part of the teaching is given in sections of five or six, in the wards of our infants' and children's hospitals, and it is this class of teaching which we think most of at Harvard. The other methods are simply preparatory, and in order to systematize the student's knowledge of the subject and to crystallize his ideas.

Recognizing what I have told you concerning the importance of anatomy, physiology and pathology in the study and teaching of pediatrics, they should be made a part of the curriculum of all advanced medical teaching, as should a course on laboratory therapeutics. We expect that the anatomic department will give an especial course on the anatomy of children, and the physiologic department has intimated that it will also give especial physiologic instruction in connection with infancy and children, preparatory to our later clinical teaching in the hospitals. In this way only can pediatrics be thoroughly and intelligently studied, and the young physician can not acquire a proper knowledge of infants and of children if his anatomic knowledge comprises only the anatomy of a later period, as is usually the case in most of our medical schools in the past. There is just as much reason in preparing students for the clinical study of infancy and childhood, by especial anatomic and physiologic teaching, as that such preparation should be made for the clinical medicine of adults.

Bearing all these facts in mind, we are deducing from them a system for teaching in the department at Harvard certain practical measures which we expect to carry out and perfect when the buildings and hospitals of the new medical school are erected. In the first place, we expect to teach the diseases of the first two years of life, in a hospital built and arranged for this age, and to have another hospital arranged for the needs of sick children between 2 and 12 years of age, with especial arrangements for the teaching of the different diseases as they occur at that period. We have also decided that such diseases as scarlet fever, measles, diphtheria, varicella and pertussis are so essentially connected with the early periods of life that they should be taught in the department of pediatrics, and with this end in view an assistant professor who has control of the fine department for contagious diseases in connection with the Boston City Hospital has been placed in the department of pediatrics.

There is another question that is of importance in looking on the study of pediatrics in this broad way, namely, that a thorough knowledge of the subject is of inestimable value to the practitioner of medicine, whether he be the so-called general practitioner, or whether he devotes himself entirely to children. The treatment of diseases in children is not necessarily a specialty. The physician can only decide how much of this clinical medicine he is able to practice or to teach well, by gauging his own capabilities to grasp the especial subject and his opportunities of so doing. There is surely enough to be learned and enough to be done in the clinical medicine of infancy and children to more than fill the time and tax the brain of the average practitioner. It is needless to say how important a great deal of knowledge of infants and children is to the general practitioner of medicine. When we consider how it is usually through the younger members of the household that the young physician enters into his practice, it is very evident that much more study in the practice of pediatrics is needed by the average practitioner, especially when we see how numerous are the mistakes and how bad the results of his treatment; in fact, it not infrequently occurs that the child is found to be suffering, not from the terminal processes of the disease which it has just been treated for, but from the inappropriate treatment to which it has been subjected.

In conclusion, let me express the hope that I have not dwelt at too great length on a subject which has only recently gained recognition as one worthy to be raised and placed on a level with other great departments of medicine. It is my belief that as time goes on the leading medical schools of this country will adopt a policy similar to that which I have outlined as prevails in Harvard University, and I shall merely say, in parting, Godspeed to the development and teaching of pediatrics in your great city.

THE TREND OF MODERN SURGERY.*

JAMES E. MOORE, M.D.
MINNEAPOLIS.

Westerners as a class have the reputation of thinking well of themselves and of being rather boastful of their achievements. It is very evident that others would not think well of us if we did not think well of ourselves, and it is now conceded by those whose good opinion we prize most highly that western surgeons have accomplished much of which they may be proud and even a little boastful. Most of those present have been obliged to do surgery under a serious handicap. We have had no marble walled operating rooms and no rich endowments. We have been obliged to build our hospitals as we went along and our endowments are yet to come. In short, we have had opportunities only as we have made them. It is this ability to overcome obstacles and to make opportunities that characterizes the western man. Western surgeons are proud of the fact that, notwithstanding the many disadvantages they have labored under, they are not now accused of making up the rear guard in the surgical procession.

At the organization of the American Surgical Association in 1882 one of the leading surgeons of the day said, "In my opinion surgery has nearly reached its limits. I do not see how it can advance much beyond its present height of perfection," yet in twenty years that have elapsed since that statement was made surgery has made more advancement than in all time before. The profession has

* President's Address before the twelfth annual meeting of the Western Surgical and Gynecological Association, held at St. Joseph, Mo., December 29 and 30, 1902.

been swept by such a wave of optimism, aggressiveness and surgical furor that it behooves us to scan closely our present trend. What is there in the present tendencies of surgery that makes for good and what for ill? That the general trend is toward better things all will agree, but that there are some dangerous tendencies all must admit. It is well for us occasionally to see ourselves as others see us. To this end I wish to quote briefly from an editorial which appeared in the *Minneapolis Daily Tribune* on the occasion of Dr. Lorenz's too much advertised visit to Chicago.

Reaction from the Knife.—The brilliant operations in bloodless surgery which the Austrian, Dr. Lorenz, is conducting in Chicago and elsewhere, call attention to a distinct reaction from lavish use of the surgeon's knife which is appearing in the higher levels of the profession. It is time for a counter revolution in this direction. Tremendous impetus has been given to the use of the knife in surgery by the two discoveries of anesthesia and antisepsis. Surgeons began to carve more freely when they found a way to do it without causing torture to their victim. But their power to explore the human interior was limited by the perverse habit of dying after the operation. In many cases this was due to the secondary cause of blood poisoning, which was largely removed by the later discoveries of antiseptic surgery. Then came a perfect riot of cutting and slashing, attended undoubtedly with great benefit to the human race. It would not become laymen to say that this has gone too far, because intelligent surgery always weighs carefully the chances of death and recovery, with or without an operation. If it was a great gain for humanity to learn how to use the knife with less danger to the patient, it will be a greater gain to learn how to dispense with the knife in many cases.

While we can not endorse this editorial, there is some truth in it. Our only defense is that while we do go to extremes at times there is no greater tendency in that direction among surgeons than among any other class of men. Even newspaper men by trying cases "out of court" succeed in hanging some innocent men and assisting some guilty men to escape. Surgeons are accused of being over aggressive, but the aggressor is far less dangerous than the obstructionist, and he has the saving grace of learning something while the obstructionist never learns. Even extremists have their uses. We do not look to extremists for the best in anything, yet if it were not for them we could not know our limitations. The editor just quoted, like many medical men, has a wrong conception of conservatism. He seems to think that conservatism consists in not using the knife, when we all know that the knife in judicious hands is the greatest conservative agent at our command. True conservatism consists in doing that which will the most surely prolong human life and prevent suffering. Surgeons are more truly conservative now than ever before because they save more lives and prevent more suffering than their predecessors ever did. Surgeons should not be held responsible for the work of the would-be surgeons found in every community where surgery is being done. Their ranks are filled up with young men not yet out of their medical swaddling clothes, and with older men without experience and proper training who are seeking for a royal route to fame and fortune. Their work is at times appalling and none deplore it more than the surgeons. The time will come—and it can come none too soon for the welfare of suffering humanity and the honor of surgery—when the law will require of a man that he shall have had hospital experience and shall have shown special qualifications as a surgeon before he will be allowed to perform operations involving life and death. A diploma from the best of medical colleges is no criterion, for not all physicians, not even all good physicians, can become surgeons.

Medical colleges are trying to turn out better educated medical men by raising their standard of entrance and lengthening their college term. There is no question but that the tendency is toward better education, but there is great room for improvement yet. The lengthening of the college term from two to four years unfortunately does not mean that the student spends twice as much time in studying the diagnosis and treatment of disease. So much of his time is taken up by laboratory work that he has very little more time to study medicine than he had when the course extended over but two years. We must not forget that we are trying to make doctors out of these young men and not embryologists and bacteriologists. We can not all be bacteriologists any more than we can all be surgeons. Much of our laboratory teaching at the present time is theoretical and of very little practical value. There is no crying need of half-baked medical men; why not extend the course to six years and limit the laboratory work to the first two? We certainly should do this or make the laboratory course a requirement for entrance to the medical course, leaving a full four years for the study of medicine. Our institutions have been spending so much money building and equipping laboratories that they have little or none left for hospitals and clinics.

We make this criticism of medical education in order that we may more consistently criticise the teaching of surgery. Our didactic teaching has improved and is still improving very materially. The didactic lecture, given alike to freshmen and seniors, is fortunately a thing of the past. It has given place to graded instruction and recitation. Our clinical teaching of surgery, however, is very faulty. The average surgical clinic has been very aptly likened to a continuous vaudeville performance. There is too much of major and too little of minor surgery. It is of infinitely greater value to a student to see a finger amputated or a fracture treated than it is for him to see an abdominal operation. The students see so much major surgery and so many brilliant results that they naturally think it is easy and that they can begin doing that kind of surgery as soon as they get out of college. This is certainly a bad tendency, but one that is easier to find fault with than to remedy. The remedy is for the medical colleges to furnish the clinician with abundance of material and with the same facilities for graded instruction that are furnished to the laboratory teachers, and to so compensate him financially that his only hope of reward is not through the advertisement he may get from his clinic. Eminent jurists and theologians are not obliged to charge their time spent in teaching to the advertising account. They have too much good sense to allow themselves to be placed in any such position. The position of the average clinical teacher is all wrong, and the humiliating part of it is that it is all his own fault. We as surgeons can fully appreciate the value of laboratory work, but as teachers we should insist that it shall supplement and not supplant the teaching of medicine and surgery. One of the great advances surgeons have made is the supplementing of clinical diagnosis with laboratory diagnosis.

The tendency now is to give the patient a more thorough and careful examination than we formerly did, making use of many scientific mechanical devices to aid us. Each year some new devices are added to our

armamentarium and old ones are being improved on. At the present time no one who is imbued with the prevalent professional spirit thinks of listening to a patient's tale of woe and then writing a shotgun prescription. On the contrary, a careful and systematic physical examination is made and the patient gets fewer drugs than ever before. This method of examination is the outcome of specialism.

The one thing that has had more to do with the advancement of medicine and surgery than any other is specialism. It stands to reason that one who devotes his whole time to one branch of the profession can do better work than he otherwise could. A specialist who has not graduated only yesterday, but who has developed from a general practitioner is certainly in a position to do better for the community and for himself than if he were to try to cover all branches throughout his professional career. One of the bad tendencies of the day is for young men to go directly from college into special work before they know to what line of work they are best adapted and before their knowledge is broad enough for good general work and while it is utterly inadequate for special work. When so many new things were added to medicine specialism became a necessity, and it in turn has developed the science of medicine to a degree that could not otherwise have been attained. As soon as men began to devote their whole attention to some one branch of the profession they became more expert in old methods and discovered many new ones. Twenty-five years ago the oculist and aurist was practically the only specialist known. Then came the gynecologist, but as long as he confined himself to the local application of nitrate of silver, to glycerin and tannin tampons and pessaries, he made very little progress. Very soon, however, he began to do plastic surgery, which lead to pelvic surgery. From pelvic surgery he soon passed on up to the diaphragm and out through the abdominal wall to the breasts, when he began to lose his identity and to become a general surgeon. The consequence is that there are fewer gynecologists now than there were ten years ago. The gynecologist developed the science of abdominal surgery, for which we owe him an everlasting debt of gratitude. At the present time the bulk of most general surgeon's work is abdominal surgery. It is absurd to maintain that the surgeon who can do good work in the upper part of the abdomen can not do equally good work in the lower part, and vice versa.

Fifteen years ago there were very few specialists in general surgery. There were none in the West, and, in fact, it was not believed possible for a man to get enough surgery to keep him busy. About this time, however, a few pioneers began to realize the great possibilities of surgery as a specialty, and the consequence is that to-day we have specialists in surgery in every city of consequence throughout the land, and the more surgeons there are the more surgery there is for them to do. New fields have been entered each year and the end it not yet.

Hospitals are being established without number, and it will be interesting to note the results. Many of them being poorly equipped and poorly manned will doubtless close, but others will remain a blessing to their communities and to the profession. The good country hospitals will be helpful to the metropolitan hospitals because they will educate the country people to the hospital idea and teach them the possibilities of surgery. We will find that the more hospitals there are the more surgical cases there will be to fill them. The modern hospital, with its trained nurses, is a very essential part of modern surgery, and the rule now quite generally adopted by surgeons that every patient requiring an operation must go to a hospital when it is possible, has much to do with advancing surgery. The people in the cities have already learned that a hospital is not a charnal house, but a harbor of safety. We find very little difficulty now in persuading our patrons to go from the finest homes to the hospital. The country people already know something of this, and through the country hospitals will soon learn more. We of the larger cities need not fear the competition of the country hospital, because much that will be done there would otherwise be undone.

A few years ago when our present technic was being developed many of the papers read were on that topic, but now we are so content with our methods that the technical paper is the exception. There is even a little tendency to criticise one who writes a paper on technic as though this subject were settled for all time, but this is wrong, for great as have been our improvements we have not yet attained to perfection. It has been suggested by a recent writer that a uniform standard of technic be established, but it is questionable whether this can ever be brought about, and if it could be done it is not desirable, for technic is the work of human hands and can never be perfect. An established standard would imply perfection which would prevent progress. The early history of antiseptic surgery was an illustration of our tendency to go to extremes. Our very elaborate technic at that time made us seem ridiculous in the eyes of unbelievers and the laity. There is a very wholesome trend now toward simplicity in technic. The best surgeons are those who have the least paraphernalia and who make the least fuss about an operation.

Strong chemicals are rapidly disappearing from our operating rooms and are giving way to soap, water, brush, boiled instruments and rubber gloves. The late Lawson Tait builded better than he knew, for when he thought he was denouncing antiseptic surgery he was really teaching us aseptic surgery. We have even learned that an operation can be conducted more satisfactorily and comfortably without flooding everything with water. There should be but one rule in aseptic surgery, viz., absolute surgical cleanliness, brought about in the simplest manner possible.

The tendency in the West is to abandon all unabsorbable buried sutures. One who becomes accustomed to catgut uses it more and more, until he finally uses it for everything but the intestines and the integment. One accustomed to it finds no objection to it.

One of the most hopeful signs of the times is the great interest surgeons take in each other's work. A spirit of kindly criticism prevails that is helpful to us all. So much good surgery is being done everywhere that it is quite the proper thing now for surgeons to visit each other and make comparisons which are bound to prove beneficial. We have always traveled East for surgical light, but at the present time there is a very respectable and rapidly increasing return current toward the West.

In conclusion: Let us continue to work so that it can not be said of us twenty years hence that we did good work for a few years and then folded our hands and said we have attained to such a height of perfection that farther advance is impossible. Let us continue to work, still admitting that there is room for advancement, not being content with our laurels until we shall have at-

tained the millennium when there will be no disease and no suffering.

Let us then be up and doing,
With a heart for any fate;
Still achieving, still pursuing,
Learn to labor and to wait.

A MODIFICATION OF PANAS' OPERATION FOR PTOSIS.

FRANK ALLPORT, M.D.
Professor of Ophthalmology, Chicago Policlinic; Ophthalmologist and Otologist to St. Luke's and Wesley Hospitals, etc.
CHICAGO.

Panas' operation for ptosis probably yields better results, on the whole, than any other operation, and yet its various steps are not always clearly understood by

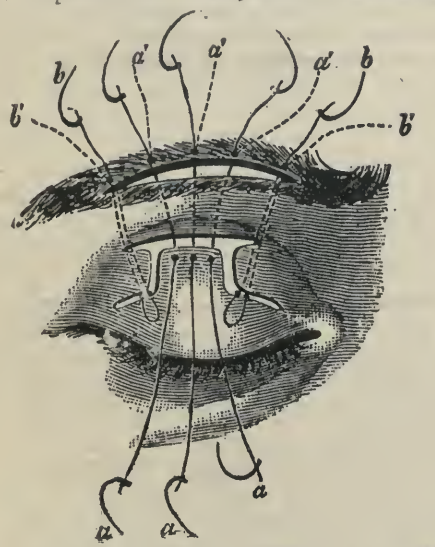

Fig. 1.—Panas' operation for ptosis. (After Panas.)

operators, and it possesses some glaring defects that have served to render it rather unpopular. It is for the purpose of clearing up these misunderstandings and

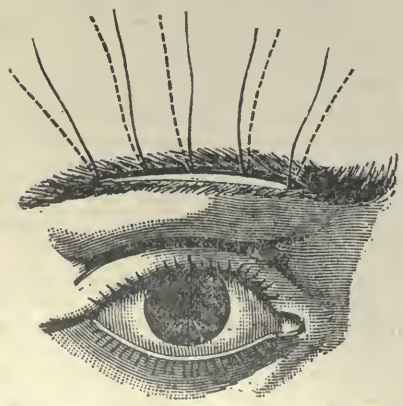

Fig. 2.—Appearance after the operation is completed. (After Panas.)

remedying the defects that I have ventured to offer this communication.

I will first reproduce the drawings usually given to clarify the written description of Panas' operation, and it will be seen that they do not entirely clear up some of the points in the ordinary description.

I think that the addition of a plain schematic drawing would better demonstrate the different steps in the operation, and for this purpose at my clinics I draw a plan like Figure 3.

The line indicated by 1 represents the first incision, which should be in the eyebrow and extend to the bone. The line indicated by 2 represents the second incision, which should be just below the eyebrow, and should extend also to the bone. The bridge of tissue between these two incisions should not be more than 5 or 6 mm. in width. The line marked 7 represents the palpebral margin of the upper lid. The line marked 3 represents a short incision in the lid at about the upper margin of the tarsal cartilage, and should be from 8 to 10 mm. long, and should pass completely through the skin. The line marked 4 represents another similar incision in the opposite angle of the lid. The lines marked 5 and 6 represent two incisions passed completely through the skin and uniting 3 and 4 with 2. While incisions 3, 4, 5 and 6 are being made, the horn spatula should be placed underneath the lid, both to facilitate the making of the incisions and to avoid accidents to the underlying eyeball. The tissue between incisions 5 and 6 should be about 15 mm. in width.

Figure 1, as given by Panas, shows all the lines, etc.,

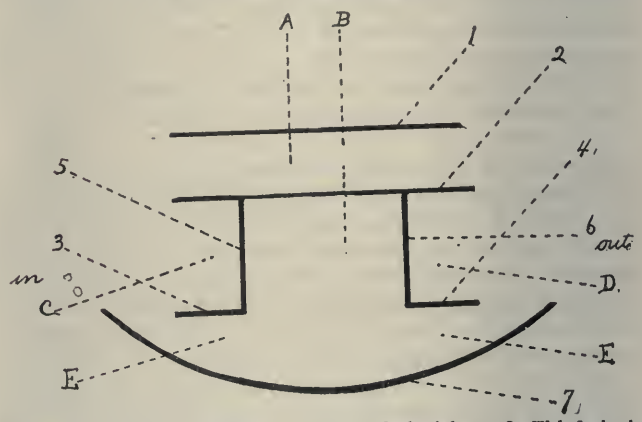

Fig. 3.—1. First incision. 2. Second incision. 3. Third incision. 4. Fourth incision. 5. Fifth incision. 6. Sixth incision. 7. Edge of upper lid. A. Bridge flap. B. Tongue flap. C. Nasal flap. D. Temporal flap. E. Palpebral flap (nasal side). E. Palpebral flap (temporal side).

to be beautifully curved in outline, but in practical work these curves are not feasible, and I believe straighter incisions can be much more accurately made, and will not detract from the efficiency of the operation.

The original drawing of Panas (Fig. 1) is misleading, as it shows the two threads in the five needle holes in the superior portion of the eyebrow incision, both coming out of the same needle hole, whereas they should be shown as coming out of separate needle holes, side by side and close together, as shown in Figure 4, which I would suggest as in every way a plainer drawing than Figure 1.

The description as given by Panas is also not explicit concerning the sutures 4 and 5, which are placed to prevent a tendency to ectropion induced by the traction effect of sutures 1, 2 and 3. These sutures should include the tissues of the lid except the skin and tarsal cartilage, and should be inserted in the spaces between the skin flaps. One of the needles of a double-needled thread should be inserted directly through the lid from within outwards, just above the upper edge of the tarsal cartilage, and pulled through, after which the other needle should be inserted through the tissues, also from within outwards, and brought out close to the first point of entrance of this suture, leaving the loop of the suture on the conjunctival surface of the lid. The lid should

be held well away from the eyeball either with the fingers or forceps during the entire placing of these sutures, so that the operator may look under the lid and see what is transpiring, and so that the needle may not injure the eyeball. The sutures should then be passed up under the bridge flap, and through the superior margin of the brow incision and firmly tied.

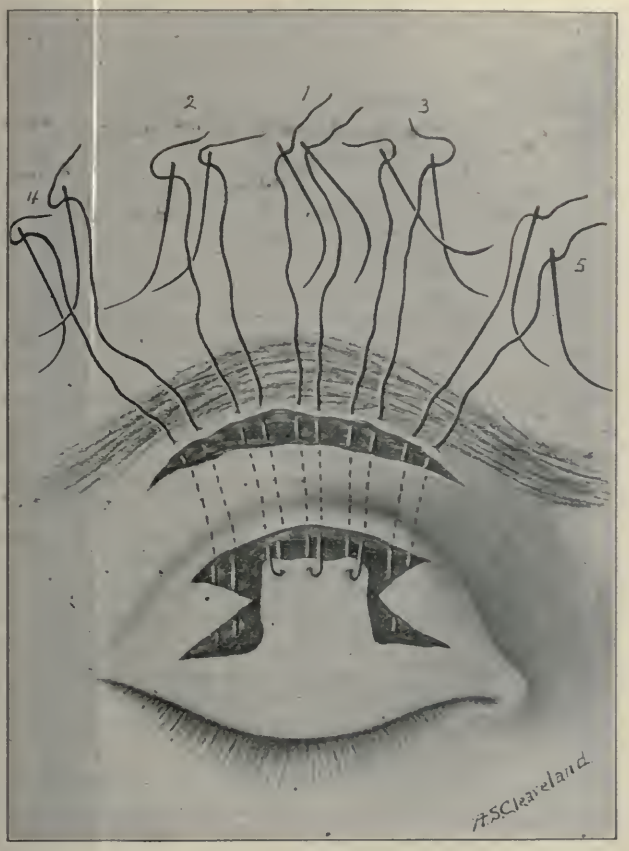

Fig. 4.—1. First suture. 2. Second suture. 3. Third suture. 4. Fourth suture. 5. Fifth suture.

One great objection to the operation is the fact of the non-adherence between the flap marked B (Fig 3), which I will call the tongue flap, and the flap marked A (Fig. 3), which I will call the bridge flap. The upper surface of the tongue flap is unbroken skin, that of the

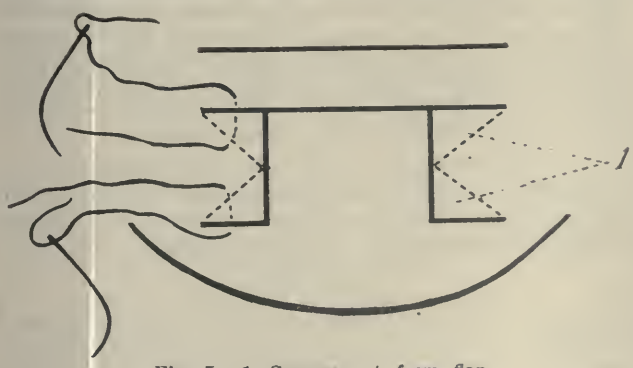

Fig. 5.—1. Corners cut from flap.

under surface of the bridge flap is connective tissue, fat, etc., and the two do not heal together, which leaves a pocket or cul-de-sac between the two for the permanent accumulation of various forms of debris, which is both unsightly and unhealthy, as well as being a distinct defect in the operation. This objection I remedy by thoroughly scarifying the skin surface of the tongue flap by criss-cross incisions, and then removing most of the dermal epithelium by delicate forceps and scissors. This procedure is accomplished before the tongue flap is dissected from the underlying tissue, as the flap is then firm, and can be handled easier than after it is lifted. The sutures are then placed and the tongue flap drawn up under the bridge flap and tied, and in a few days perfect adhesion will take place. Another objection to the operation is the thick, lumpy appearance of the bridge flap, which never entirely disappears. This objection I minimize by making the bridge flap as narrow as possible, never more than 5 or 6 mm. in width, and also making it as thin as possible by stripping it of all possible tissue beneath the true skin.

The last objection to the operation is the two pieces of skin at the angles of the lids marked C and D in Figure 3, which pucker up and look permanently bulky

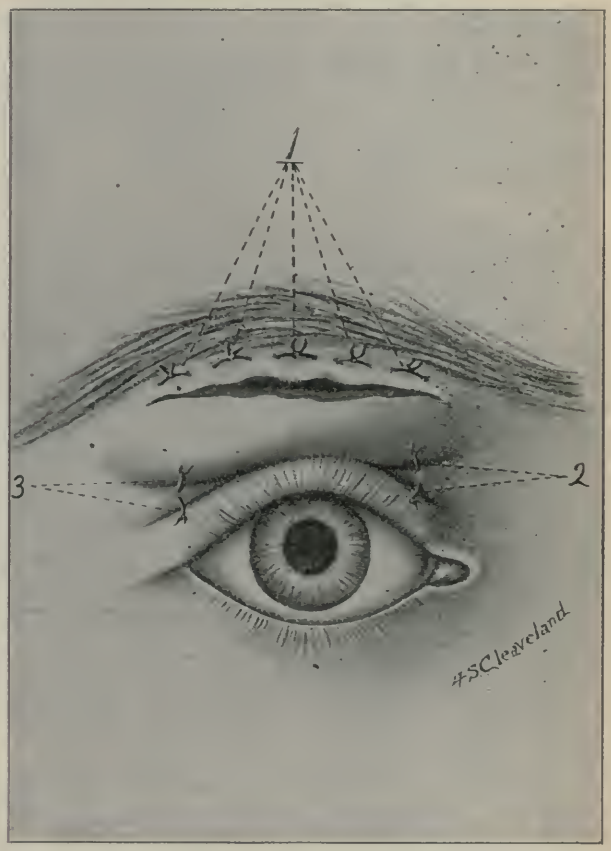

Fig. 6.—1. Sutures 1, 2, 3, 4, 5, after being tied. 2 and 3. Sutures in flaps C and D after being tied.

and unsightly. This I remedy by cutting off the corners as seen in the dotted lines of Figure 5, and then thinning the under sides of flaps C and D (Fig. 3) by removing all possible tissue except the true skin. Flaps C and D (Fig. 3) are then sutured to flaps E and E (Fig. 3) and flap A (the bridge flap) by four sutures, which makes the entire field of operation present a smooth and finished appearance and adds much to the cosmetic effects of the operation, as shown in the completed operation of Figure 6.

I have performed the operation as thus outlined a number of times, and have not failed to obtain satisfactory results.

Crystallized Wisdom on Epidemics.—In these days there are no excuses for epidemics of filth diseases; there are only explanations of them.—"N. Y. Times."

THE EXTERNAL PREPARATIONS AND THEIR THERAPY.

CARL S. N. HALLBERG, PH.G.

Professor of Pharmacy in the School of Pharmacy, University of Illinois; Member Committee of Revision U. S. Pharmacopeia.

CHICAGO.

While the history of the preparations embraced in the broad generalization of external preparations is of the most ancient origin, yet their evolution and differentiation along therapeutic lines is largely a matter of recent development.

Up to a comparatively recent period the fats employed for vehicles of the oleagenous preparations were selected with sole reference to their pharmaceutic properties, that is, to afford preparations possessing the most desirable physical characteristics: proper consistence, ready fusibility, etc. The earlier materia medica was especially rich in oils and fats of animal origin, the fat of nearly every creature being vaunted as having especial virtues, such notions still surviving among many peoples, as, for example, bear-grease to promote the growth of the hair; goose-grease to loosen and break up a cold; rattle-snake oil as an application for rheumatism, and many similar domestic remedies.

OINTMENT VEHICLES.

The introduction of the petroleum fats or soft paraffins, in 1870—cosmolin and vaselin—was a great advance over the rancid and otherwise often decomposed mixtures of animal and vegetable fats, mostly used before this time, and the substitution of these practically inodorous and unchangeable soft paraffins for the latter became quite general. The immiscibility with water and watery liquids of the soft paraffins was the only drawback to their more extended use, until about 1882 the purified wool-fat appeared under the name of lanolin. The peculiar property of this cholesterin, even after being hydrated, to take up its own weight of water at once attracted attention, and when its power to penetrate the skin was subsequently discovered it began, though slowly, to be recognized as a valuable medium by which systemic effects may be obtained through the skin. While the fat from wool was used by the ancients under the name of "Œsypus," to Oscar Liebreich is due the credit of presenting a pure hydrated form of it under the name of lanolin, official as adeps lanæ hydrosus, U. S.

THERAPEUTIC GROUPING.

The at first more or less empiric use of these two fats —the soft paraffin and lanolin—of exactly opposite qualities as regards their water miscibility and property to penetrate the skin, led eventually to the grouping of the ointments and similar preparations from a therapeutic standpoint, according to the vehicle employed, substantially as follows:

1. *Epidermatic:* Non-penetrative, or non-absorptive. Protective, antiseptic. Vehicle: Soft paraffin, vaselin or petrolatum, U. S.

2. *Endermatic:* Semi-penetrative or semi-absorptive. Emollient, nutritive, astringent, etc. Vehicle: Animal or vegetable fats, oils and waxes. Lard, suet, oils of almond, olive, etc.

3. *Diadermatic:* Penetrative or absorptive. Systemic or constitutional. Vehicle: Lanolin or hydrated wool-fat.

While this classification is a generalization, its approximate correctness is apparent from the fact that a vehicle consisting of equal parts of petrolatum and lanolin, the respective types of the two extreme groups, has the general properties of the intermediate endermatic group. Since this vehicle does not become rancid or react with chemicals, as do the animal or vegetable fats and oils, it serves excellently for endermatic uses.

SUPPOSITORIES.

In no class of preparations has the failure to consider the general therapeusis been so apparent as in the suppositories. Since their first introduction into the U. S. Pharmacopeia in 1870 the vehicle has been uniformly cacao-fat or theobroma oil.

While three different forms of suppositories are recognized no distinction is made as to the vehicle employed, although the necessity for such selection is generally conceded. For rectal suppositories fats undoubtedly are the best vehicle, not only because of the alkalinity of the secretions, but also because more or less penetrative or absorptive effects are desired. Cacao-fat serves this purpose probably better than any other fat. While soap is sometimes used, its effects are simply those of an irritant or solvent, as in the official glycerin suppositories. Neither is gelatin a proper vehicle for rectal suppositories, except when used instead of nutritive enemata, where other considerations supervene.

On the other hand, the secretions of the urethra and vagina are normally acid, and fats are therefore not indicated as the proper vehicle for urethral and vaginal suppositories, but water-soluble substances should be employed. Glycero-gelatin answers the purpose probably better than most of the other substances employed, the only objection being that in melting it exudes and may mat the pubic hairs. By using 50 per cent. anhydrous glycero-gelatin mass, a soft, readily-soluble "bougie" is obtained in which tannin and similar agents may be presented without difficulty.

The late Dr. Hay of Chicago employed a vaginal suppository of elm powder which had the advantage of ready preparation in that the suppository could be easily formed into any shape desired with the fingers.

Glycero-Massa Ulmi (Elm Suppository-Mass.)—Powdered elm bark, 10; water, 6; glycerin, 6 c.c. In the water and glycerin previously mixed dissolve the required amount of the medicinal agent, add the solution to the elm powder at once, and quickly mix and form a mass, by working the mixture in a mortar. A soft, cohesive and plastic mass results which may be rolled out, divided into the required number of parts (for the above quantity of 6) and made globular by forming with the spatula and the fingers. This operation should be done quickly, since the mass hardens in about ten minutes and can not then be readily formed. Any form can easily be made in this manner without losing its shape. In about twenty-four hours the suppositories become hard and elastic.

In a suppository the medicinal agent should be most thoroughly distributed with the vehicle, as in all similar preparations, and it is worst kind of slip-shod pharmacy to use the so-called "hollow" suppositories.

CERATES.

The cerates are mixtures of fats and waxes, having a higher melting point than ointments, their firmer consistence requiring them usually to be spread on cloth and applied as dressing. They are, therefore, in the epidermatic group and comprise protective, cooling, emollient and vesicating effects. The cantharidal cerate is the most important, and when spread on adhesive plaster in such thickness as to obliterate the yellow color of the plaster cloth, when viewed through the light, it is the most effective cantharidal vesicant to be had.

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Materia Medica, Pharmacy and Therapeutics, and approved for publication by the Executive Committee: Drs. A. W. Baer, A. B. Lyons and W. J. Robinson.

PLASTERS.

This most ancient form of medication has largely fallen into disrepute during recent years, owing partly to their ineligibility and uncertainty of action, and partly to the advent of more efficacious and more quickly responsive methods of treatment. The advent of the rubber plasters has also caused the lay public, which believes in "anything that will stick," to appropriate the plasters as its own sovereign remedy for all kinds of aches and pains.

Nevertheless, the plasters serve a useful purpose owing to the great range of their application, which may be summarized in the following groups:

1. *Epidermatic:* Supportive, protective, antiseptic, counter-irritant, vesicant. Vehicle: Rubber or any suitable adhesive.
2. *Endermatic:* Anodyne, astringent, alterative, resolvent, sedative, stimulant. Vehicle: Oleates or lead plaster, sometimes with resins or gum-resins.
3. *Diadermatic:* For constitutional or systemic effects. Vehicle: Lanolin or plaster-mull.

The vehicle for the commercial rubber plasters is chiefly India-rubber, or caoutchouc, with sufficient orris powder and sometimes gum-resins, to give it the proper consistence and retain its adhesive properties. For epidermatic purposes this serves admirably as a convenient and fairly stable adhesive, but since it lacks penetrative properties in any considerable degree, it should not be used for endermatic effects, such as are sought from drugs like belladonna. The suggestion to increase the efficacy of rubber belladonna plaster by the addition of boric acid would seem also to support the view that such anhydrophile mixtures do not penetrate into the skin, as has also been clinically demonstrated.

For endermatic effects the oleates, as represented by the well-known lead plaster, are the best vehicle, since they penetrate into but not through the skin, and thus have the desired effects without producing any systemic or constitutional results. The objection to the old-style plasters with a lead-plaster vehicle, that they are impaired by age, become brittle and lose adhesiveness, has been met by improved methods of manufacture affording an adhesive plaster which retains its flexibility and through the admixture of a little rubber adheres without being artificially warmed.

For diadermatic or systemic effects the vehicle for plasters should be animal fat, such as lard or suet with waxes, or preferably mixtures of these with lanolin, substantially like the plaster-mulls of Unna. The official mercury plasters, at present made with lead plaster and gum resins, should be prepared with this lanolin vehicle.

OLEATES.

The official oleates are liquid or semi-solid mixtures of the respective oleates in oleic acid in excess which renders them often ineligible. The true oleates, or so-called "dry oleates," are preferable, but these should be diluted with a proper vehicle before use.

As indicated above, the oleates do not penetrate through the skin, which becomes self-evident when the constant use of soap (sodium oleate) is considered. While there is plenty of evidence that the natural oleates, the oils of olive and almond, also the oleopalmitates and stearates, lard, butter, etc., in which the respective acids are linked with the radical glyceryl, penetrate through the skin and are absorbed in the system, the artificial compounds of these acids with the metals and alkali bases, known respectively also as insoluble and soluble soaps, are not absorbed through external use. If it were otherwise, what an inducement for the people in "the farther Mediterranean" to consume at least some portion of their daily rations of olive oil in the form of soap.

LINIMENTS.

The value of liniments depends on the degree they penetrate into and through the skin, only one official liniment being protective, that of lime, the well-known Carron oil, so called from the factory town in England where the mixture of linseed oil and lime water originated as an application to burns. While the effects resultant from such liniments as consist of oils or soap solutions are supposed to be largely influenced by the mechanical rubbing or massage in their application, solutions of medicinal agents, such as belladonna, camphor, etc., in alcohol or other volatile liquids, are no doubt more effective when they are applied by means of an occlusive dressing as shown by the extended researches of Dr. Thos. F. Reilly,[1] presented to this association in 1900.

Several modifications have come into recent use: the saponimenta or liquid medicated soaps, which may be prepared extemporaneously from the official soap liniment or from the semi-solid form, linimentum saponatum camphoratum of the National Formulary or solid opodeldoc.

COLLODIONS.

The collodions, owing to the impervious film of pyroxylin or colloxylin which they leave on evaporation of the volatile solvent ether-alcohol, suggest a wider employment, and as being well adapted for applications on small areas, when lasting effects are desired of tannin, iodin, iodoform and similar derivatives. The official list may well be extended to include those of the National Formulary.

The linimenta exsiccantia, or the so-called drying liniments, have somewhat similar uses, except that they do not form so impervious a coating as do the collodions. the vehicle consisting of mucilages of starch, dextrin, tragacanth or albumin. The following is a type, which may be medicated as desired with zinc oxid, chrysarobin, iodoform, ammoniated mercury, ichthyol, salicylic acid, etc.:

VERNICIUM ICHTHYOLI ALBUMINATUM, UNNA.

℞.	Ichthyol sulph. ammon.	3v	20
	Starch, powder	3v	20
	Distilled water	3xv	60
Mix with:			:
	Liquid egg-albumin, recent	m. xii	75

MODERN DERMATOLOGIC PREPARATIONS.

Pastæ (Pastes—Dermatologic—Lassar, Unna, etc.)—These are mixtures of starch, dextrin, zinc oxid, sulphur or calcium carbonate, made into a paste with glycerin, soap or fat, such as petrolatum or lard, medicated with antiseptic or astringent agents. The following are important examples:

PASTA ZINCI, LASSAR (ZINC-SALICYL).

℞.	Acid salicylic	gr. xxx	2
	Zinc oxid, starch, each	3vi	24
	Petrolatum, white	3xiiss	50

PASTA RESORCINI (MITIS), LASSAR.

℞.	Resorcin	3iiss	10
	Zinc oxid, starch, each	3vi	25
	Petrolatum, liquid	3x	40

PASTA NAPHTHOLI, LASSAR.

℞.	Naphthol	3iiss	10
	Sulfur, pp	3xiiss	50
	Petrolatum		
	Soft soap, āā	3v	20

1. THE JOURNAL A. M. A., Jan. 26, 1901, p. 250.

PASTA ZINCI MOLLIS, UNNA.

℞.	Zinc oxid., calc. carb. pp., each	3vi	24
Mix these powders and incorporate gradually:			
	Lime liniment	3xiiss	50

PASTA ICHTHYOLI, UNNA.

℞.	Ichthyol, sulf. ammon.	3iiss	10
	Distilled water, glycerin, dextrin, each	℥i	30

PASTA ZINCI SULFURATA, UNNA.

℞.	Zinc oxid	℥ss	15
	Sulfur, pp.	3iiss	10
	Acid silicic (kaolin)	gr. lxxx	5
	Benzoated lard	3xviiss	70

PASTA DEXTRINATA.

℞.	Dextrin	3xxv	100
	Glycerin, distilled water, each	3xxv	100
Dissolve by heat, add water to make 300 gm. ℥x.			

This is a general vehicle for many medicated pastes used in dermatology.

PASTA KAOLINI. GLYCEROPLASMA KAOLINI.

℞.	Kaolin, elutriated and dried	3xiiss	50
	Glycerite boroglycerin	3iiss	10
	Methyl salicylate, thymol, each	gr. i	5
	Glycerin, to make	3xxv	100
Or sufficient to make a semisolid paste by thorough levigation.			

Stili (Stili Dilubiles, Unna. Pencils.)—Pencils for the direct application to the skin of medicinal agents—antiseptics, astringents, anesthetics, etc. These agents are dissolved or mixed with a paste consisting of mucilaginous or saccharin vehicles, starch, dextrin, tragacanth, sugar, etc., rolled out into sticks about 1/5 inch (5 mm.) in diameter and 2 inches (5cm.) in length, dried at ordinary temperature on parchment paper and wrapped in tin-foil.

Gelatinæ Glycerinatæ (Glycerogelatin).—Gelatin mass as a vehicle for suppositories and other external applications is used as follows:

GLYCEROGELATINA ACIDI SALICYLICI, 10 P. C., UNNA.

℞.	Gelatin	3iiss	10
	Glycerin	3xiss	45
	Distilled water	3ix	35
	Acid salicylic	3iiss	10

GLYCEROGELATINA IODOFORMI, 10 P. C., UNNA.

℞.	Gelatin	gr. lxxx	5
	Glycerin	3v	20
	Distilled water	3xvi	65
	Iodoform	3iiss	10

GLYCEROGELATINA ZINCI DURA, UNNA.

℞.	Gelatin	3iiiss	15
	Distilled water	3xiss	45
	Glycerin	3vi	24
To this add gradually the following, levigated:			
	Zinc oxid	3iiss	10
	Glycerin	3iiiss	15

Then mix with it enough water to make 100 gm. The soft form (Glycerogelatina Zinci Mollis) is prepared in the same way by using 10 gm. gelatin.

These glycerogelatins should be freshly prepared when wanted. They may be run out in molds, oiled with cacao-fat. The zinc gelatins may be used as vehicles for ichthyol, resorcin, chrysarobin, etc. When to be applied, they are melted and then penciled on the affected part.

Gelatinæ Medicatæ (Lamellæ, Eye Discs).—Discs of gelatin are made with some glycerin, containing alkaloidal salts for insertion and solution in the eye. They are applied to the eye with a pencil. The following is an illustration:

GELATINA ATROPINÆ SULPHATIS. 1-10 mg.

℞.	Gelatin	3vi	25
	Distilled water	3xxv	100
	Glycerin	gtt. vi	4
	Atropine sulphate	gr. iss	1
For 1,000 discs from a plate 7x12 inches (18x30 cm.).			

Salve Mull.—Under the name of "salbenmull," salve mulls, or steatines, ointments have been introduced of higher fusibilities spread on porous cloth, gauze or "mull" by Dr. Unna. These are mixtures of suet with lard and sometimes wax, in such proportion as to afford a consistence adapting them to being easily spread when heated without melting or running when applied to the body. They are intended chiefly for epidermatic effects, protective and antiseptic, but also for endermatic, astringent and resolvent action.

The mulls serve a distinct purpose in dermatology, since owing to the porous character of the fabric employed, they permit ready evaporation and thus prevent maceration of the epidermis which usually occurs from the prolonged application of more occlusive dressings. Their value as a form of application in intractable skin diseases has therefore been recognized by the highest authorities in this special branch of medical practice. The following are some of the most largely used:

UNGUENTUM EXTENSUM HYDRARGYRI CHLORIDI CORROSIVI. 2 p. mill.

℞.	Mercuric chlorid	gr. iii	2
	Alcohol	m. lxxx	5
This solution is incorporated with the following mixture previously fused:			
℞.	Benzoated lard	℥iv	5
	Benzoated suet	3xxiiss	90

UNGUENTUM EXTENSUM HYDRARGYRI CHLORIDI MITIS, 10 P. C.

℞.	Calomel	3iiss	10
	Benzoated lard	3v	20
	Benzoated suet	3xviiss	70

STERILE SOLUTIONS.

While many pharmacists are careful in making solutions, such as injections, eye washes, gargles, lotions, etc., the majority are not, and the result has been that many leading specialists in eye diseases, for example, prepare and dispense their own solutions, asserting that only through such procedure can they be assured of complete asepsis. The use of compressed tablets for hypodermic solutions has become general, chiefly because of their convenience and portability, but no doubt also from the fact that through their use solutions may be prepared extemporaneously with fresh water as pure as may be obtainable. In the larger cities where the water supply is more or less infected, the general practitioner no doubt is often compelled to use the service water instead of pure water, and the employment of the tablets must therefore in many instances be a source of infection. Weak, 1 per cent. water solutions of the alkaloidal salts: atropin, morphin, cocain, pilocarpin, also ergotin, permit germ growth, while concentrated solutions, i. e., 10 per cent. solutions of cocain and quinin, are easily kept germ-free. Solutions in germicidal solvents: alcohol, ether; iodin, mercuric chlorid and strong phenol solutions, are not admissible, but almond oil may be used for camphor and glycerin for iodoform. Carbolic acid—one drop for 160 minims (10 c.c.)—is the safest and altogether the best preservative for the water solutions.

Whether or not it may be regarded desirable to admit formulas for hypodermic injections into the U. S. P., there is no doubt that some general directions or formula should be introduced for sterilization. Not only for hypodermic injections are sterile solutions necessary, but also for ordinary injections, lotions or washes, nebulæ or sprays, and especially for collyria.

Dr. Fütterer, a most careful observer, reports several instances of the most serious results due to careless preparation of solutions for hypodermic use, and regards the

official recognition of a process for sterilization as of the greatest importance, since it would enable the physician to specify its employment for the preparation of solutions, etc. It would, moreover, direct the attention of pharmacists to the necessity for care in these preparations and would afford him at once an authoritative method insuring the best results.

INJECTIONES HYPODERMICAE. BR. PH. '98.

These solutions are prepared by dissolving the medicinal agent in distilled water which has just been boiled and allowed to cool. The antiseptic agents in the cocain and ergotin solutions are added before the medicinal agents are dissolved.

INJECTIO HYPODERMICA.

℞.	Apomorphin hydrochlorate .....gr. iss		1
	Ac. hydrochloric dil.....min. iss		1
	Distilled water .....min. clx	10	
℞.	Cocain hydrochlorate .....gr. xvi	1	
	Ac. salicyl.....gr. 1/4		015
	Distilled water .....min. clx	10	
℞.	Extract ergot .....gr. clx	10	
	Phenol .....gr. v		3
	Distilled water 3v	20	
℞.	Morphin tartrate .....gr. lxxx	5	
	Distilled water 3xxv	100	

The apomorphin and ergot injections are directed to be recently prepared.

ANTISEPTIC GAUZE.

Schimmelbusch, director of Bergmann's clinic in Berlin, states (1893) that moisture is one of the essentials for germ life, while "dryness" is one of its greatest enemies, and therefore dry dressing is always preferable to wet, except where the wound secretion is viscid and purulent and where the antiseptic material is employed for packing deep or incised wounds. It seems that the majority of surgeons prefer dry dressing for aseptic wounds, but wet or moist dressing for septic wounds, such as result from great laceration, etc. This question would go entirely beyond the scope of pharmaceutic discussion and is presented only to demonstrate the necessity for a distinction between wet and dry gauze and surgical dressings. While under the circumstances it may be inadvisable to recognize antiseptic gauze in the pharmacopeia, the admission of aseptic gauze would be highly desirable, either simply defined as to its character and properties, as the "tela depurata" in the German pharmacopeia and also "gossypium purificatum" in the U. S. P., or preferably by giving directions for the purification of the commercial gauze, as is done in the French codex by a process like the following:

CARBASUS ASEPTICUS.

Gauze of the required weight and mesh is boiled in water for 10 to 15 minutes, expressed, and washed two or three times in cold water. The expressed gauze is then allowed to macerate in solution of chlorinated soda for one-half hour, pressed and macerated in water containing 1 per cent. hydrochloric acid, rinsed in cold water several times, pressed, and dried in a closed vessel or sterilizer.

The gauze is quickly formed into rolls of the required dimensions and immediately transferred to sterile receptacles, preferably of tinned iron which are hermetically sealed.

DISCUSSION.

Dr. A. W. Baer, Chicago—Only yesterday I went into a physician's office in this place and saw the most complete outfit that I have ever seen. Here were all forms of apparatus for applying electricity, galvanic, faradic and static, some of which the owner would not in all probability use once a month. It occurred to me that if the pharmacist had these appliances, more especially in the smaller towns of 1,500 or 2,000 inhabitants, he might thus be of much assistance to the physician and keep himself occupied. Drugs are now only a part of the means for treating disease; and at the present day the large pharmaceutical manufacturing houses supply nearly all the preparations, to say nothing of the proprietary drugs unfortunately prescribed, thus doing the work of the pharmacist, supplanting him in his legitimate occupation.

GENERAL PUERPERAL SEPTICEMIA TREATED BY INTRA-ABDOMINAL IRRIGATION WITH NORMAL SALINE SOLUTION; RECOVERY.*

JAMES HAWLEY BURTENSHAW, M.D.
Adjunct Professor of Gynecology in the New York Polyclinic Medical School and Hospital.
NEW YORK.

A number of cases have been reported in which the abdominal cavity has been subjected to irrigation for puerperal sepsis, with indifferent results; but the accompanying report is unique, so far as I am able to determine, on account of the length of time the irrigation was practiced, the effect of the irrigation on the kidneys and peritoneum, and the ultimate recovery of the patient without the ordinary sequels of septic peritonitis.

The patient was a French woman, aged 24, unmarried, secretary to a woman of considerable wealth. She became pregnant during the latter part of August, 1902. During October and November she made frequent attempts to produce abortion by means of various drugs, hot-water vaginal douches and the like, but unsuccessfully. Early in December a meddlesome woman friend initiated her into the mysteries of instrumental procedure, and during the evening of December 9 she inserted an ordinary wooden penholder into the cavity of the womb and allowed it to remain there until the following morning. The membranes were not ruptured by this maneuver, but it was followed by the appearance of considerable blood, undoubtedly from a wound of the endometrium.

Abortion occurred during the afternoon of the 10th. The girl remained in bed until the next morning, when she arose, dressed, and resumed her usual duties about the house. I was summoned to see her at midnight, December 16. She had then been confined to bed two days. I found her temperature to be 104.4 F., her pulse rate 120, and her respiration rapid and shallow. She was somewhat delirious. Her abdomen was greatly distended, and was sensitive to the touch. The uterus was enlarged and soft, and the lochial discharge was scanty in amount and very offensive. From the housekeeper I learned that she had had several protracted chills, had vomited a number of times, and, to the best of the housekeeper's knowledge, had urinated but once during the previous twenty-four hours.

I catheterized her, and drew off all the urine the bladder contained, about four ounces. Later examination of the specimen demonstrated a specific gravity of 1,031, numerous hyaline casts, and a considerable amount of albumin. I may state here that a blood examination the following day showed the presence of almost innumerable streptococci, while the uterine scrapings developed streptococci and staphylococci in great numbers.

I flushed out the uterine cavity with two gallons or more of hot water, and, under very superficial chloroform narcosis, gently curetted it with a broad curette, taking great care not to abrade the endometrium. Considerable foul-smelling placental tissue and blood-clot were removed in this way, and the cavity was again copiously irrigated, this time with a 1 per cent. solution of lysol. I then introduced a suppository containing one dram of iodoform, fifteen grains of starch, and glycerin into the uterus, and packed that cavity and the vagina lightly with iodoform gauze. Nearly a quart of hot saline solution was then slowly introduced into the bowel, but the retention

* Read before the Polyclinic Clinical Society.

of even a small quantity of the fluid caused the patient so much pain that the enteroclysis was not persisted in. Meanwhile, I had opened the median basilic vein of the left arm and withdrawn about eight ounces of blood. This was replaced by about eleven ounces of hot normal salt solution. Marked improvement in the patient's pulse and respiration was at once manifest. Her body was then sponged with tepid water and alcohol, cloths wrung out in ice water were applied to her head and abdomen, and she was again catheterized. Two ounces of urine was obtained. A rather free, loose bowel movement had resulted from the attempt at enteroclysis. It was my intention to practice continuous irrigation of the bowel with the salt solution, but the patient complained so bitterly when the procedure was attempted that I desisted.

At 11 o'clock the next day, December 17, her temperature was again 104 F., having dropped during the early morning, after the infusion, to 103; her pulse was still 120, her breathing was rapid, and coma was developing. Only seven ounces of urine had been obtained by catheter. Subcutaneous infusion of saline solution was resorted to, the sites of the injections being the anterior border of the right axilla and under the left breast. The uterine and vaginal dressings were removed and a second iodoform suppository was introduced into the uterus, both cavities again being packed. The posterior vaginal fornix was markedly distended, owing to the presence of fluid in the peritoneal cavity. Absorption from the cellular tissue was extremely slow, although the patient showed temporary improvement after the injections were begun. Enteroclysis was again practiced, but with very unsatisfactory results.

I had intended to open the posterior cul-de-sac and pack the pelvis with iodoform gauze, but the grave condition of the patient, especially the almost complete cessation of kidney function, appeared to preclude all hope of success attending this procedure. The approximate quantity of urine passed during thirty-six hours had been nineteen ounces.

It then occurred to me that thorough irrigation of the entire abdominal cavity with normal saline solution might accomplish several things: first, remove the collection of serum, which undoubtedly already was infected by streptococci; second, through absorption by the most extensive lymphatic system of the body, the kidneys would be more quickly and radically influenced; and, third, the general agglutination of the peritoneal surfaces as a result of the inflammation might, to a certain extent at least, be prevented.

Digitalin, strychnin and whisky had been injected hypodermatically at intervals since the night before. Several gallons of normal saline solution, prepared according to the formula of Locke, containing sodium chlorid, 3 iiss; calcium chlorid, gr. 3¾; and potassium chlorid, gr. iss to the quart of sterilized water, was prepared and kept at a temperature approximating 110 F. A four-quart fountain syringe and tube were sterilized by boiling. The patient was given a few whiffs of chloroform, and I made a two-inch incision into the abdominal cavity midway between the umbilicus and pubes. A rubber pad was placed under her to catch the overflow, and the tube of the syringe was inserted through the opening as far as possible into the pelvis.

For one hour the solution was permitted to flow into the cavity without intermission. Several times during this period the patient was turned on her side, and once on her abdomen, and pressure was made on her flanks to facilitate the exit of the fluid. At first, when this was done, the fluid returned was of a yellow tinge and contained many lymph flakes, but later it came away perfectly clear. Twenty minutes after the irrigation was begun ten ounces of urine of a specific gravity of 1,024 was obtained by catheter, and fifteen minutes later, six ounces. At the end of the hour her temperature had dropped to 102.6 F., her pulse rate to 110, she was in a profuse perspiration, and her mental condition had greatly improved. In all, forty ounces of urine had been drawn from the bladder, the last being of a specific gravity of 1,013. Five ounces of whisky had been given by the mouth. At one time syncope appeared to be imminent, but was averted by raising the foot of the bed to the level of a chair seat.

At 10 o'clock at night the irrigation was repeated for half an hour. A self-retaining catheter had kept the bladder drained, and forty-eight ounces of urine had been collected. The bowels had moved freely twice. At midnight her temperature was 102 F., and her pulse rate 116. A third irrigation was practiced the following morning, again for half an hour, and at three-hour intervals until 1 o'clock the next morning the cavity was filled with the saline solution. The next day, December 19, I closed the abdominal wound with stitches under cocain anesthesia. Her temperature then was 100.4 F. and her pulse rate 100. From 10 o'clock on the night of the 17th until noon of the 19th 210 ounces of urine were collected by catheter.

On December 20 her temperature and pulse rate were practically the same as on the day before, but her general condition had greatly improved. By December 23 the abdominal tenderness, except in each iliac region, had almost disappeared, the lochial discharge had increased in quantity and had ceased to be offensive, and all signs pointed toward recovery. On December 25 she had a decided increase of temperature during the afternoon, but this yielded readily to a moderately large dose of quinin. Intrauterine suppositories, each containing 20 grains of iodoform, were employed daily, and the uterus and vagina were lightly packed with iodoform gauze from December 18 to 22.

The patient was allowed to sit up January 4, and February 1 I examined her at my office. I found the uterus to be in good position and freely movable, but enlarged and somewhat sensitive to the touch. Both ovarian regions were sensitive, and the left ovary was enlarged. I could discover no evidence of pus foci in either broad ligament or elsewhere. Her bowels were constipated, but movements were unaccompanied by pain. The usual sequels of peritonitis appeared to be entirely absent.

In reviewing the line of treatment adopted in this case a number of pertinent queries are in order.

First.—Was there not danger of "drowning" the patient by introducing such great quantities of fluid into the abdominal cavity? I confess that I feared this might be the outcome, and had the kidneys not begun to functionate almost immediately after the irrigation was begun would have discontinued it at once.

Second.—Could not the same favorable result have been attained by intravenous infusion? So far as influencing the general systemic infection was concerned, I unhesitatingly reply in the affirmative, the opinion being based to some extent on recent reports of *lavage du sang* in streptococcic infection with a solution of formalin. In the cases reported, however, I believe that the favorable outcome was due to dilution of the poison in the blood current, and not to any germicidal influence exerted by the contained drug. The use of normal salt solution, I feel sure, would have been attended by as good results.

With regard to the attendant peritonitis, it undoubtedly was the local action of the saline which cut short the inflammatory process and which apparently prevented adhesion formation. I am able to explain this action only on the theory that, as streptococcic infection having the uterus as a starting point spreads to surrounding structures especially through the medium of the lymphatics, and as saline solution in the peritoneal cavity, as elsewhere, is primarily absorbed by the lymphatic system before entering the blood current, the consequent attenuation of the toxins almost at the point of origin would necessarily follow. Then again, while the primary effect on the blood vessels of hot water, that is, of water at a temperature ranging from 107 F. to 120 F., is to cause dilatation, and consequent engorgement, through the governing nerve mechanism, the secondary effect is that of contraction and cessation of congestion. As congestion is a natural concomitant of irritation, or

inflammation, the effect produced by its disappearance is obvious. While this explanation appears plausible, I am compelled to ignore the fact that the peritonitic inflammation in this case was of streptococcic origin, and consequently of a type which would be the least likely to yield to any form of treatment.

As regards the nonformation of adhesions, it is natural to suppose that, the inflammation of the peritoneum being held in abeyance and the surfaces being separated by the fluid, no opportunity would be afforded for such adhesions to occur.

Third.—Was there not danger of over-stimulating the kidneys? This factor was before me during all the time the treatment was being carried out. The conditions under which the infusions were given made it impracticable to measure the quantity of fluid administered, and I have no means of knowing even the approximate amount absorbed. The urine collected was carefully measured at frequent intervals, and it was evident that the flow from the kidneys was almost constant from the beginning. It also occurred to me that such long exposure of the intestines to the action of water at a temperature of 110 F. might have a deleterious effect, but such did not prove to be the case.

It is to be regretted that bacteriologic examinations of the blood were not made at intervals subsequent to the one made after the venesection. Two specimens were obtained for this purpose, but, owing to an error, were lost.

I am inclined to think that the satisfactory outcome was in part due to the character of the fluid employed. Dr. Harvey Cushing has called attention to the fact[1] that a solution containing 0.6 per cent. of sodium chlorid, that commonly employed, should not be regarded as a normal physiologic salt solution. He says:

> As a matter of fact, this is a most misleading designation, if we mean to imply by the term a fluid which is isotonic with the body fluids, and thus one that may be used with impunity in large amounts to replace directly in the circulatory system the loss of normal blood serum. A 0.6 per cent. salt solution is, in the first place, sufficiently hypisotonic to lake the corpuscles perceptibly if used in sufficient quantity and, furthermore, the recent observations of Loeb and his pupils have demonstrated the actual toxicity toward cellular activities of the pure sodium chlorid solution, that is to say, when uncombined with other salts. . . . Sidney Ringer, years ago, through an accidental observation, discovered the fact that minute doses of calcium and of potassium salts, when used in combination with the usual percentage of the sodium salt, made a solution possessing a much more beneficial effect in conserving the activity of an isolated heart than the sodium solution when used alone. Thus, for the first time, was pointed out the antagonizing action of small amounts of calcium and potassium toward the toxicity possessed by the single sodium ion, and thereby was given the first indication of the necessity of combining salines in order to obtain a more perfect infusion solution. . . .
>
> There can be no doubt that the pure sodium chlorid solution alone may, in certain ways, be injurious from its toxic effects; that, furthermore, a solution of the single salt, as weak as the 0.6 per cent. commonly employed, has a hemolytic effect on the red corpuscles. The desirability, therefore, of administering a fluid which shall be as nearly as possible isotonic with the blood—that is, shall have a molecular concentration corresponding to that of the liquor sanguinis—is evident.

381 West End Avenue.

Heat relieves the pain of inflammation, but increases that of suppuration. This is a valuable diagnostic aid in appendicitis.—"Med. Fortnightly."

FISTULA BETWEEN THE GALL BLADDER AND THE STOMACH.

A. BARR SNIVELY, M.D.
WAYNESBORO, PA.

The cause of fistula between the gall bladder and stomach is primarily cholecystitis with formation of one or more gallstones, which by irritation cause inflammation resulting in plastic peritonitis with adhesions to the surrounding structures. The gall bladder contracts and its walls become thickened and friable. The constant pressure causes the stone to produce an ulcer which develops into a fistula. This is Nature's cure, and may also be attended by no new symptoms or the previous ones may be relieved, especially if the stones pass into the stomach and if there is no obstruction in the cystic duct and the adhesions are not numerous enough to cause trouble.

A cholocystico-gastric fistula is relatively rare, the operative cases recorded, as far as I can find, being four in number. The following table affords information as to the varieties of fistulæ resulting from cholecystitis and their frequency in recorded cases taken chiefly from Courvoisier:

Fistulæ between the bile ducts themselves	8
Fistulæ between the bile ducts and retro-peritoneal tissues	4
Fistulæ between the bile ducts and the stomach	12
Fistulæ between the stomach and the liver	4
Fistulæ between the stomach and gall bladder	8
Fistulæ between the bile ducts and the duodenum	108
Fistulæ between the gall bladder and the duodenum	93
Fistulæ between the gall bladder and the jejunum	1
Fistulæ between the gall bladder and the ilium	1
Fistulæ between the bile ducts and the colon	50
Fistulæ between the gall bladder and the colon	49
Fistulæ between the common bile duct and colon	1
Fistulæ between the bile ducts and urinary passages	6
Fistulæ between the bile ducts and the thoracic viscera	10
Fistulæ between the bile ducts and the abdominal wall	184

Adopting Mayo Robson's statistics, out of a table of 10,866 autopsies made by Roth, Schroeder and Schloth, biliary fistulæ occurred 43 times. Fistula between the gall bladder and stomach was found only once. In general the cases of such fistulæ between the gall bladder and stomach give no symptoms, if any, none other than those of cholecystitis or cholelithiasis. Fistulæ between gall bladder and stomach are not always due to gallstones. Murchison records a case in which there was a fistulous opening between the dilated bile duct in the liver and the stomach. In this case, which was one of cancer associated with impaction of gallstones in the common bile duct, the bile flowed through three or four rounded orifices in the interior wall of the stomach, which communicated with the dilated bile ducts and superficial portion of the liver. This was evidently the source of the bile found in the stools during life.

Cancer of the gall bladder has been known to invade the stomach and thus bring about fistulous communication by ulceration. Ogle reports a case where the perforation of a simple ulcus ventriculi into the gall bladder caused a fistula.

Nichols, in an admirable paper, reports the case of a woman aged 85 dying two weeks after having an impacted fracture of the femur. At autopsy eight hours after death the stomach was found almost empty. The stomach walls were atrophied. The stomach was long and fusiform. The gall bladder was adherent to the stomach one-half inch from pylorus. A fistula between the gall bladder and stomach was found large enough to admit a small probe.

Mayo Robson mentions two cases, one of probable diagnosis, the patient having vomited gallstones, the other an operative case, where a fistula was found and adhesions separated. The edges of the fistula were pared

and closed with two rows of sutures; while the opening in the gall bladder was utilized to remove the gallstones and afterward to allow drainage. The patient made an excellent recovery and is now in good health.

Kehr, who has reported a series of 409 abdominal sections on account of assumed or acutally present cholelithiasis, with 3 3/10 per cent. mortality, mentions one case of gall bladder stomach fistula found in a patient where he drained the common bile duct; later a gastro-enterostomy was done, the patient dying eight days afterwards, unfortunately, of cholemic hemorrhage. He says:

A fistula between the gall bladder and stomach may, for example, develop entirely without symptoms, and only rarely will we be able to diagnosticate fistula of the gall bladder and stomach. But in most instances we will make the diagnosis not before or during the formation of the fistula, but first, as a rule, after it. This is incidentally remarked, also, quite well, for in general it is wrong to disturb the procedures of a natural cure. If stones are vomited, then one may not yet say that they have reached the stomach through the unnatural fistula. Just as easily as bile flows backward through the pylorus, even as easily can small stones come into the stomach and be vomited. In case of the vomiting of a large stone, the suspicion of a fistula between the gall bladder and the stomach is justified.

Oschner mentions one case of perforation of gall bladder into stomach. Naunyn, in statistics taken from Courvoisier, cites eight cases of cholecystico-gastric

Fig. 1.—Gallstone (natural size). This stone is irregular in outline, is in no way faceted, indicating in a general way that the gall bladder contained no other stones. One can hardly imagine a stone of this size and shape escaping into the duodenum via the common duct and further, examination of the common duct at the time of operation did not show any thickening or the presence of adhesions as we would naturally expect had such a stone at one time lodged in the duct.

fistulæ. Murchison gives twelve instances in which gallstones were vomited, but only one of these cases, namely, that reported by H. Jeaffreson, was proved by autopsy to result from gastro-cholecystic fistula. Cruveilhier narrates a case where the fistula between the gall bladder and stomach was found plugged by a gallstone. Oppolzer describes one in which the fistula was close to the pylorus. Frerichs, quoting Baille and Weber, refers to two cases.

The following case which I have to report of Mrs. M. of Altoona, Pa., was diagnosed by her family physician, Dr. E. E. Neff, through whose kindness I am able to present the following history:

She is 53 years of age, has had four children, the youngest of which is aged 22. This woman has had symptoms of gallstones since the birth of her last child. She has had colic from time to time during this period. Five years ago she had an attack of typhoid fever, being ill ten weeks. Dr. Neff saw her for the first time Oct. 21, 1899, in an attack of cramp, with all the symptoms of gallstone colic. By the free use of cathartics and turpentine stupes the patient was relieved until Dec. 27, 1899, when he was again called and found her in an attack more severe than the former one. The pulse was 96, temperature 99, respirations 20, and the abdomen was somewhat distended, tense, tympanitic, and there was apparently entire cessation of peristalsis. A mass could be felt over the region of the gall bladder, giving pain on pressure and causing nausea, as though an edged instrument was being forced through the back.

December 28 the treatment was the same as in the former attack. The symptoms continued, abating for a short time and then coming on as severe as ever. The temperature and the pulse were the same. In the morning a high enema of glycerin was given; in the afternoon a large enema of white of egg and turpentine was administered, with some relief.

December 29 there was no change in the condition. A high enema of sweet oil and water was given with no apparent effect. About 8 p. m. a second enema of sweet oil was given; flatus now suddenly escaped with a report that could have been heard in the adjoining room. Peristalsis now started, and the symptoms gradually abated. The patient passed about 75 to 80 gallstones. The patient had had eructations of gas and bile in its purity. The abdomen became flaccid; the tympany disappeared. The pulse was 100, temperature 99, respirations 24. The patient had a restful night. December 31 the patient feels fairly well, there was some tenderness over the entire abdomen, more especially over the pyloric end of the stomach, which gave pain when palpated. The patient expectorated bile continually. Magnesium sulphate and olive oil were administered to keep the bowels moving.

Jan. 1, 1900, at 2 a. m., the patient had a return of the cramp and passed 97 more gallstones. The pain subsided immediately, and she felt entirely relieved. About two hours later she complained of a stoppage in the rectum and, on examination, Dr. Neff found a large stone which had lodged there (Fig. 1). This was easily removed with long forceps.

The patient steadily improved in strength, the bowels, however, continued to be very sluggish, and she complained of a burning sensation in the stomach. Operation was advised and insisted on repeatedly, but the patient flatly refused surgical interference. Any sort of food, predigested or otherwise, which was taken into the stomach gave pain as soon as it touched the stomach walls. The raising of bile was more marked at times, seeming as though the gall bladder had filled to the opening in the stomach, overflowing and causing nausea, expectoration and wretching, also causing the abdominal muscles and tissues around the gall bladder to contract and force most of the bile out. Dr. Neff said that the following symptoms caused him to make a diagnosis of a fistulous opening between the gall bladder and stomach:

1. Eructations of bile and gas from the stomach.

2. The tender spot persisting in the region of the pyloric end of the stomach.

3. Continuous obstinate constipation, which looked as though the lubrication were being removed by some other way—namely, by mouth.

4. Pain when anything was taken into the stomach.

This woman, while on a visit in Waynesboro, Pa., May 23, had an attack of gallstone colic lasting three hours, until relieved by hypodermic injection of morphia. The attack did not recur after the use of morphia. On May 25, I called in consultation Dr. Thomas S. Cullen of Baltimore, who advised operative procedure.

Operation May 29, Church Home, Baltimore, by Dr. Cullen, assisted by Dr. Gavin and myself. An incision was made to the outer side of the rectus, the gall bladder was small, and found to be intimately adherent to the stomach and surrounding structures (Fig. 2). The adhesions were gradually liberated until we came to a point where the gall bladder was fused to the stomach over an area fully 1 cm. in diameter. There was a distinct opening between the stomach and gall bladder at this point. The fistulous tract was divided and the stomach wound turned in on itself and closed with mattress sutures. The region of the gall bladder was carefully packed off and the gall bladder opened and drained. Two stones in the cystic duct were gradually forced up into the gall bladder and removed. The patient stood the operation well. On May 30, she had a chill, her temperature ran up to 105. Her

pulse was very rapid, but she was in fairly good condition. The temperature dropped the next day, but two or three days afterwards rose to 106. Since that time it rapidly came down to normal. She is very much better and her general condition is excellent. Patient continued to improve, and was discharged apparently cured, the first week in July. There was no escape of bile, and the abdominal incision had nearly closed. Since which time the patient has been able to indulge in a very liberal diet with no discomfort whatever and has led a very comfortable life. The operation demonstrated the fact that the pain produced by the ingestion of any food or liquid whatever was caused by the stomach pulling on the adhesions with which it was fastened to the gall bladder, liver and intestine.

Sept. 22, 1902, the subject of this sketch, after eating a hearty supper of tea, toast, soft-boiled eggs and sliced tomatoes, had a violent attack of gallstone colic; morphia was given hypodermically and, after a short while, patient was relieved. On examining the abdomen there seemed to be an abscess forming in the line of the incision. The point at which this ap-

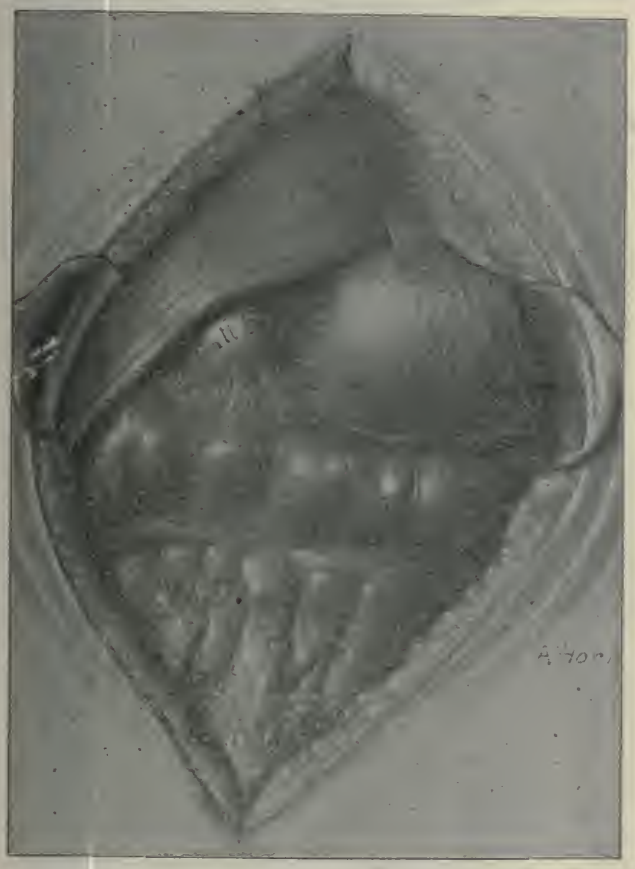

Fig. 2.—Gall bladder as viewed on opening the abdomen. The incision has been made through the right rectus muscle. The gall bladder is seen adherent to the stomach and to the transverse colon and there are adhesions between the surface of the liver and stomach. On separation of adhesions the condition detected in Fig. 3 was found.

peared was about 1 cm. in diameter. Two hours later this ruptured and about one quart of clear, thin, almost straw-colored bile was discharged. After this the stiffness of the muscles and the pain about the waist-line entirely disappeared. For three days the stools had no sign of bile and were of oatmeal-like appearance. On the fourth day they commenced to have the normal bile stain. About 50 very small gallstones now passed, and the fistula ceased discharging and rapidly granulated and closed. These gallstones had evidently come down from the liver and blocked up the common duct, as at the time of the operation the common duct was patulous. Since this time the patient has been regularly taking Sprudel salts and has had no discomfort in region of gall bladder, and has gained about twenty pounds.

Jan. 20, 1903, I received a further communication from Dr. Neff, stating that for some time he had noticed a swelling in the region of the gall bladder, which gradually increased in size and at one point there was pain on pressure. There was also a burning sensation extending through to the back in the vicinity of the lower angle of the right scapula.

On January 16, following the usual dose of Sprudel salts and oil, she felt something give way in the vicinity of the swelling and had a very copious stool, composed principally of bile. Next day a second copious stool, containing a large quantity of bile, was passed. The patient experienced a great deal of pain with the escape of the bile and, to use her own words, "It was as if coals of fire were passing through the bowel." After the escape of the large quantity of bile the swelling entirely disappeared. There has evidently been an acute inflammation of the common duct, followed by marked dilitation of the gall bladder.

The subsidence of the inflammation in the duct has allowed the gall bladder to completely empty itself.

Addendum: April 1, 1903. Dr. Neff reports the patient as in very good health and leading a very normal life with no sign of a return of the trouble.

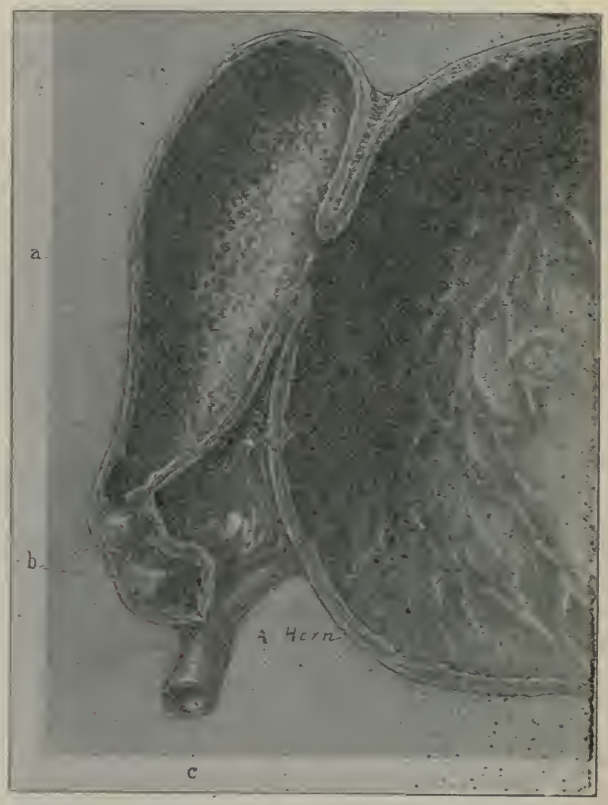

Fig. 3.—Fistula between the gall bladder and stomach. The gall bladder is densely adherent to the stomach and at *a* is a fistulous opening nearly 1 cm. in diameter between the gall bladder and the stomach. In the cystic duct are two small stones, indicated by *b*. These were readily pushed up into the gall bladder and removed. *c* is the common duct. At operation the stomach was freed from the gall bladder and the fistulous opening closed by a double row of silk sutures. The gall bladder was drained.

Mayo Robson sums up the subject of biliary fistulæ as follows: "Many of the fistulæ are mere pathologic curiosities, quite undiagnosable, and only capable of being discovered postmortem. Many must form and heal, leaving the patient cured, and thus are they not only not discovered, but they are probably not even suspected, for contrary to what one might suppose, fistulæ between the bile passages and the hollow viscera in the majority of cases heal spontaneously, leaving only visceral adhesions; so that the fistulæ are comparatively rarely found postmortem." It will thus be seen that the elaborate

figures given by Courvoisier and Naunyn can only give a very imperfect estimate of the frequency of these fistulæ which must be constantly overlooked or not recorded.

LIGHT IN THE TREATMENT OF LUPUS AND OTHER CHRONIC SKIN AFFECTIONS.

J. W. KIME, M.D.
SUPERINTENDENT BOULDER LODGE SANATORIUM FOR TUBERCULOSIS.
FORT DODGE, IOWA.

Light and especially concentrated actinic light derived from the sun, is a specific in the treatment of lupus, chronic ulcers and other destructive lesions of the skin.

The first essential in the treatment of this class of cases is a practical and efficient apparatus, one with unlimited power and yet so easily manipulated that any physician may successfully operate it. The instrument which I use consists of a modification of the ray filter used in photography, and at a distance of 18 inches focuses, to a very fine point, a violet-colored light. At its smallest focal point it is intensely hot, but I have found that in certain cases nothing short of this strongly concentrated irritant light will sufficiently arouse the tissues to action to start the process of repair which, once started, continues to complete recovery.

The cell used is so constructed that it is readily adjustable at any angle to catch the rays of the sun. With the sun as a source of light the supply is unlimited, its strength is the greatest, it is richest in actinic power; it is, in fact, the one source from which all other lights are ultimately produced by means of mechanical appliances.

The light from the sun is accessible to every physician and it is free for the using. With a beam of sunshine one foot in diameter falling through the office window the instrument is ready for use.

The manner in which I treat lupus is as follows: The surface of the wound is first thoroughly cleansed, all scabs and crusts being removed, and it is then washed with water. I have avoided antiseptics as I wished to determine accurately the specific action of the violet rays. After this cleansing, I seat the patient with the cell placed between him and the sun and at a distance of about eighteen inches from him. I go over the entire wound surface and coagulate the albumin in the tissues until it is of a smoky white color. This usually takes but a few minutes. The treatment is then turned over to the nurse, who seats the patient a little farther from the glass, or a little nearer to it, so that the true focal point of the lens is avoided, and with the light strong, yet comfortably to be borne, she continues the application of the light for about twenty minutes.

A wet dressing of absorbent cotton and water is then applied until the following morning, when she removes the dressing and applies the weakened light for twenty minutes and reapplies the dressing. This dressing is again changed in the evening. The following day she repeats this treatment in like manner, and on the third day I usually apply the strong light again, especially to any part which seems to be lagging behind in its response to the irritation produced. In this manner the treatment is continued until healing is complete.

Around the edges of the wound granulations spring up within a few days, new integument begins to form around the borders, and gradually the size of the wound diminishes until complete restoration takes place.

Fig. 1.—Method of use of lupus machine.

I wish to emphasize the importance of the physician's applying the strong light himself and the necessity of closely watching that the parts are thoroughly cleansed twice each day. It is of the greatest importance that all crusts and scabs be kept from the wound, as these seem to be especially damaging to the process of repair.

The action of actinic light possesses a twofold potency: it is strongly germicidal and it is powerfully irritant to the tissues. By its irritant action an increased blood supply is furnished, new food is brought in abundance to the starving tissues and a retrograde

metamorphosis is converted into a reconstructive process. By its germicidal action a malignant sore is converted into a simple one, and Nature brings about the cure in the ordinary way.

Figs. 2 and 3.—Lupus vulgaris of nose.

In this connection will be recalled our treatment of chronic ulcers ten years ago, when we criss-crossed their

Figs. 4 and 5.—Lupus vulgaris of neck.

surfaces with deep cuts of the knife with a view to bringing about repair by the irritation produced by the

Fig. 6.—Lupus of cheek.

injury wrought by the knife. We now curette these ulcers with the same object in view. The irritant action of chemical light is much greater and can be extended to any degree at the will of the operator.

The apparatus used needs but little explanation, as it is very simple in construction and is easily operated. The solution of copper used is combined with alcohol to prevent freezing. The lupus lens consists of a plano-convex lens of eighteen inch focal length and is six inches in diameter. Behind it, at a distance of three-fourths of an inch, is placed a circle of plain plate glass. Between the lens and the plate glass is the space for the blue solution, which both cools the heat of the sun's rays and absorbs all but the blue rays, which contain

Fig. 7.—Same as Fig. 6. After treatment.

little heat, but are rich in chemical power. The lens is so mounted that it may be readily adjusted at any angle and the stand is of sufficient height that the patient may be seated in a chair while he receives treatment about the face or head. It may be dropped lower for use on other portions of the body.

The following records are presented as typical of results produced in the manner described:

Fig. 8.—Chronic ulcer of leg.

Case 1.—M. K., age 21, domestic; has had lupus vulgaris on left side of nose for one year. Father died of lupus and from effects of operation for it. Two points shown in cut were involved. She has tried various washes and ointments. August 9 light treatment was begun. Light was used daily for half an hour until September 1. No nodules then remaining, treatment was discontinued. September 20 ulcers were completely healed. There has been no relapse during two years' time. See Figs. 2 and 3.

CASE 2.—M. G. has had lupus on side of neck six months. It has ulcerated deeply into the tissues of the neck, is one and one-half inches in length and one inch in breadth. She began treatment in April, 1901. All nodules had disappeared May 1. No relapse. See Figs. 4 and 5.

CASE 3.—Anna K., age 35, domestic. Mother died from tuberculosis. Present trouble, lupus, began two weeks ago. When first seen it had penetrated all the layers of the skin. There were several smaller patches near the angle of the mouth. Three treatments with light near the cautery point effected a cure. See Figs. 6 and 7.

CASE 4.—Fig. 8 shows result obtained in chronic leg ulcer of one year's standing in a man 52 years of age. Site of ulcer six inches above left ankle. The ulcer was about the size of a silver dollar. Light was used for six weeks, at the end of which period healing was complete.

Strongly concentrated actinic light is a most efficient remedy and it should be generally adopted by the profession that the quacks may not reap a harvest from its irregular and illegitimate use.

THE THERAPY OF DYSENTERY.

WILLIAM ROBERTS, M.D.
Lieutenant Assistant-Surgeon, U. S. A. (Late of Manila, P. I.)
FORT BRADY, MICH.

The therapy of dysentery is at present in no sense specific. While the causative agents have clearly set a dividing line between the amebæ on the one hand and bacteria on the other, the resulting treatment of either has not been uniformly successful. Quinin in amebic cases with the intention of killing the causative agent is highly irritating, as might have been expected, and does not reach all the amebæ, while the serum therapy of the cases of bacterial origin is in its infancy, though so far well spoken of.

This paper contains no new plan of treatment, for it is on the use of ipecac in dysentery, but the narration of several cases will illustrate what can be attained with this old and well-tried remedy.

The profession in India has established certain axioms in the administration of ipecac, and they are good today:

1. The dose must be large.
2. Its safe passage through the stomach without inducing nausea is of paramount importance.
3. It must contain all the active principles of cephaelis ipecacuanha.
4. It should be used early in every case, before pathologic changes occur in the intestines

Attempts to use a refined ipecac have not been followed by good results. The method of securing the passage of the drug into the intestines with as little nausea as possible was by having the stomach empty, by counter-irritation to the epigastrium and by partly stupifying the patient with opium, but at times this fails to keep the patient from rejecting the remedy. Coating boluses of ipecac with salol was considered by the writer in order to avoid the action of ipecac on the stomach. Salol being insoluble in the gastric contents, the bolus passes on to the duodenum where the salol is dissolved and the ipecac liberated, where it undergoes some change in the presence of the intestinal juices which prepare it for its therapeutic mission.

The ipecac is first made, *secundum artem,* into large pills containing one-half gram each, which when dry are placed in liquid salol, either melted by heat or dissolved by ether. Each pill is picked up on the point of a pin and withdrawn, the coating being accomplished in a short time. Ipecac prepared in this manner was used in the following cases, with uniform success both as to the safe passage of the drug through the stomach and prompt arrest of the disease:

CASE 1.—A. B., female, aged 45; American; seen in consultation; had been ill eight days. Diagnosis: acute specific dysentery, due to Shiga's bacillus. The patient was semi-comatose; pulse thready; there was considerable shock, and between thirty and forty discharges a day. She had been under saline purgation and rectal irrigation. Four grams of ipecac made into boluses coated with salol were administered. She immediately improved and subsequently recovered.

CASE 2.—A. C., female, aged 30; American; seen in consultation; had been ill for ten days, and was having twenty-five to seventy-five operations a day. There was tympany over the region of the descending colon, vesical and rectal incontinence, dry pointed tremulous tongue, anxious expression, considerable nervous and arterial depression, great weakness and constant nausea. The stools showed no amebæ; the Widal reaction was negative to Shiga's bacillus. Diagnosis: acute dysentery; cause unknown. She had been on saline and other unrecorded treatments. Seven grams of ipecac in boluses coated with salol were given. Operations ceased and prompt recovery followed.

CASE 3.—A. D., male; civilian; aged 25; American; had been suffering from discharges of blood and mucus for two months, was advised to go to the hospital, but declined. He was directed to go to bed and take seven grams of ipecac in boluses coated with salol, which he did, going to work the following day. He was seen four days later, and reported the disappearance of all blood and mucus, and that he was having one normal operation daily. He had been having from eight to fifteen operations a day prior to his treatment.

All cases of severity will not answer so promptly any more than will every case of malarial infection answer equally well to quinin; but if used early and in sufficiently large doses ipecac is probably more of a specific for dysentery than any other remedy of which we know at present. Most of the medical literature dealing with dysentery refers to ipecac with more or less praise. Dujardin-Beaumetz maintains that ipecac acts as a cholagogue aperient, and Yeo states, "Whether ipecacuanha acts in this way or not or as a special antidote to a specific poison, it is undoubtedly the most valuable remedy we possess for dysentery, especially in the acute form." Cunningham is reported as giving sixty to ninety grains of powdered ipecac, which, he says, "causes much nausea and vomiting, together with reduction of pulse rate, profuse perspiration, cessation of pain and tenesmus, and quieting of the bowels for twelve to twenty-four hours, the next motion being soft, fluid and free from blood or mucus."

A résumé of all the various articles of the materia medica which have been used from time to time in the treatment of dysentery can not but impress the reader with the utmost universal praise with which ipecac is mentioned. It is true other remedies have been extolled from time to time, but their history shows them to have been "the things of a day," and that ipecac deserves in some measure the encomiums awarded.

In 1672 ipecac was known in Europe. John Helvetius, grandfather of the famous author of that name, having been associated with a merchant who had imported a large quantity of ipecac into Paris, employed it as a secret remedy, and with so much success in dysentery and other bowel affections that general attention was drawn to it, and the fortunate physician received from Louis XIV a large sum of money and public honors on the condition that he should make it public. Local remedies and dietetic régime are indispensable in rendering comfort and aid to patients, but none can be said to produce a specific action nor are they followed

by such prompt relief as may follow the administration of ipecac in the therapy of dysentery.

In an article by Joseph Ewart, in which he outlines the usual ipecac treatment, going to great pains to impress the reader with the importance of avoiding emesis, he states that the drug should be repeatedly administered in order to secure its retention, and that:

The signal for the relinquishment of these doses is freedom from tormina and tenesmus, with the occurrence of refreshing sleep, feculent, bilious, or ipecacuanha stools, and restoration of the primary processes of assimilation. If no great amount of disorganization of the mucous membrane has taken place, these favorable changes are frequently noticed after the administration of the first or second dose. . . .

When ipecac fails to preserve the life of a patient its failure may generally be attributed to: 1, co-existence of abscess of the liver; 2, unchecked malarial poisoning; 3, permanent enlargement of the spleen, or liver, or both; 4, irretrievable constitutional cachexia; 5, Addison's disease; 6, morbus brightii; 7, phthisis; 8, strumous disease of the mesenteric glands; 9, peritonitis with or without perforation of the gut, or, 10, the existence of extensive sloughing or gangrene.

The advantages of the ipecac treatment—for the revival of which the profession in India and England is indebted to Mr. Scott Docker, of the Second Battalion of the Seventh Royal Fusiliers, stationed at the Mauritius—in the congestive, exudative and ulcerative stages of almost every form and type of acute dysentery, may be briefly stated. They consist in:

1. Its simplicity, its safety and its certainty, compared with any other method.
2. The promptitude with which the inflammation is stopped.
3. The rapidity with which repair takes place, (*a*) by resolution, or (*b*) by granulation and cicatrization.
4. Conservatism of the constitutional powers.
5. Abbreviation of the period required for convalescence.
6. Decrease in the frequency of recurrence.
7. Decrease in the frequency of abscess of the liver.
8. Diminution of mortality in cases treated.

All of these results are accomplished without calomel or other irritating purgatives or opium. There is no other remedy of which report speaks so highly as of this, and it is assumed that it has succeeded when the rest have failed, and its early use in every case is recommended.

Antitoxic or protective sera in the treatment of dysentery is noted as "doubtful but hopeful," in an article recently prepared by R. C. Cabot. Flexner states, as a result of his labors in this city, that "it is not unreasonable to hope that with the discovery of the specific cause of dysentery, particularly if it be a bacterium capable of being artificially cultivated, means will be found by which protective inoculation may be carried out with effect and safety. The fundamental conditions underlying such immunizations are now fairly established, and two general methods of accomplishing such results are open to investigation. In the first place, an active immunity may be achieved through the use of cultures of a determined grade of activity; in the second, the serum of animals may be employed either as a therapeutic agent or to provide a passive immunity.

"It has been found possible, through the use of cultures destroyed by heat or by the addition of chemicals, to protect small animals from the effect of subsequent inoculations of the virulent bacilli; large animals, such as the goat, when treated first with the dead and afterwards with the living cultures, develop a gradually increasing resistance to the inoculations, their blood serum assumes highly agglutinative qualities for the bacillus and, coincidentally, acquires protective and healing qualities.

"My own experiments relating to this topic have been carried out on small animals only, as no patients with acute dysentery have been seen by me since the serum from the goats has been available. Shiga has, however, been able to test the serum on human cases. According to Dr. Eldridge, up to Nov. 1, 1899, Shiga had treated with serum cases as follows:

1898.—In Laboratory Hospital: 65 cases, death rate 9 per cent.

1899.—In Laboratory Hospital: 91 cases, death rate 8 per cent.

1899.—In Horowo Hospital: 110 cases, death rate 12 per cent.

"During the period of 1899 there were under ordinary treatment at Tokyo:

At Horrjo Hospital: 116 cases, death rate 37.9 per cent.
At Horowo Hospital: 53 cases, death rate 37.7 per cent.
At Komagonic Hospital: 398 cases, death rate 34.7 per cent.
In private houses: 1,119 cases, death rate 28.5 per cent."

The application of curative sera to diseases of man was looked forward to as the utopian period of scientific therapeutics. Our expectations have been disappointed in more than one instance, but it is to be hoped that a serum of sufficient potency for the cure of dysentery will be given the medical world ere the present decade ends.

The chief objection to the use of ipecac being its frequent rejection, its use in compressed pills coated with salol is recommended as one method by which nausea and vomiting can be avoided, thus securing the full action of a remedy of world-wide repute in the treatment of dysentery, but a remedy often robbed of its specific virtues by faulty administration.

POST-OPERATIVE PULMONARY COMPLICATIONS.*

REUBEN PETERSON, M.D.
Professor of Gynecology and Obstetrics, University of Michigan.
ANN ARBOR, MICH.

In April, 1901, at a meeting of the Chicago Gynecological Society, I reported two cases of lobar pneumonia following operations. Both cases occurred in my practice within a single month, and were my first experience with this complication in a ten years' surgical practice.

In the first case, a young girl on whom I performed Alexander's operation, there was a distinct history of a cold, contracted shortly before the administration of the ether. The patient had a chill and rise of temperature within three hours after the completion of the operation. But one lung was affected, and the patient made a good recovery. The second case occurred in a patient from whom I removed a tube and ovary and suspended the uterus. The symptoms were not so severe as in the first case, nor could any history of exposure be elicited. She also made a good recovery.

At the same meeting Frankenthal reported a fatal case of double lobar pneumonia following an abdominal operation. Two other patients who were being prepared for operation at the same hospital about this time died from pneumonia before the operations were performed. This fact led Frankenthal to conclude that the pneumonia was not so much due to the ether or septic causes as to the great prevalence of la grippe at certain seasons of the year.

* Read by invitation before the Wayne County Medical Society, Detroit, Dec. 15, 1902.

Two cases of pneumonia, three cases of pleurisy and a single case of bronchitis following operations performed in my service at the University of Michigan Hospital during the past fourteen months, have renewed my interest in this variety of post-operative complication. Of the two cases of pneumonia, one died and one recovered.

Case 1.—*(Gynecologic Case 159).—Bilateral Salpingo-Oophorectomy for Cystic and Atrophic Appendages. Appendectomy. Lobar Pneumonia on Second Day. Death on Eighth Day.*—The patient, aged 39, married twenty-three years, had suffered for a long period from pelvic pain and tenderness. March 18, 1902, the adherent tubes and ovaries were enucleated by the abdominal route and removed. As the appendix showed signs of chronic inflammation, it also was removed. The operation was free from shock. When the ether was started, the patient's right eye was seen to be edematous and the conjunctiva injected. At the time no importance was attached to this condition.

The next day the eye symptoms had increased and, on investigation, it was found that the patient had shown symptoms of having taken cold a day or two prior to the operation. Forty-eight hours following the operation, the patient was seized with a severe pain in the right lower thorax and corresponding shoulder. The signs of pleuro-pneumonia gradually became distinct. By the fifth day there was dulness over the entire lower right lobe, with the usual accompanying signs of consolidation. Dr. Dock was called in consultation and obtained, by aspiration through the eighth interspace, a considerable amount of bloody serum. The relief, however, was only temporary. The signs of consolidation grew more marked, the temperature ranged higher and the pulse grew more rapid and thready. The patient died on the eighth day following the operation. Unfortunately no autopsy could be obtained.

Case 2.—*(Gynecologic Case 293.)—Vaginal Celiotomy; Vaginal Suspension of the Uterus by the Round Ligaments. Bilateral Trachelorrhaphy. Perineorrhaphy. Acute Lobar Pneumonia on the Third Day. Recovery.*—The patient, aged 35, married, had shown no pulmonary symptoms prior to the operation performed, Nov. 21, 1902, which was simple and devoid of shock.

On the third day following the operation she complained of feeling chilly, and there was an immediate elevation of temperature to nearly 104. The fever remained at about this point until the crisis on the ninth day. For the first two or three days of the disease, cough was not a prominent symptom and only appeared on deep inspiration. It was at no time troublesome, and there was little if any expectoration. The physical signs of the lesion in the right lung were somewhat obscure at first. There were few adventitious sounds, and it was not until the sixth day that dulness over the affected area was marked. A slight change in the percussion note existed from the start and, with the other signs, left no doubt as to the presence of a central lobar pneumonia of the right side. There was a pseudocrisis on the eighth day. On the following day the temperature reached normal, there was a rapid clearing up of the lung, and the patient made a good recovery. The vaginal wounds healed by first intention.

Why did these patients contract pneumonia after their operations? Was the pneumonia due to direct irritation of the anesthetic, an ether pneumonia? Was it of septic origin? Could it have arisen from exposure and chilling of the patient during the operation? Such questions as these will arise in the operator's mind when a patient has pneumonia after an operation, unattended, as a rule, by much risk or mortality.

The distinctions between the kinds of pneumonia developing after surgical operations are not always borne in mind. Such a pneumonia may be an infectious disease, a true lobar or croupous pneumonia, or it may be an inhalation or bronchopneumonia. It has long been recognized that the last form is far from being uncommon after certain operations or when certain types of patients are operated on. Bronchopneumonia is apt to follow operations on the pharynx or larynx, and is very common after tracheotomies. The etiologic factor here seems to be the aspiration into the air passages of minute particles of food, which set up a severe inflammation in the finer bronchi. It is a true capillary bronchitis and its severity is directly proportionate to the amount of lung tissue involved. Bronchopneumonia also is apt to follow the administration of an anesthetic with or without operation in persons in the extremes of life. It is this factor which makes emergency operations, such as strangulated hernia, in young infants or children so much more dangerous than in adults. Very old people or those with weakened constitutions are also liable to develop bronchopneumonia after an anesthetic. Alcoholics are especially prone to this complication.

It is not so well known that true lobar pneumonia is not such an uncommon sequela of operative procedures. W. H. Prescott[1] looked over the records of various Boston hospitals for the purpose of ascertaining the frequency of this complication and could find only five authentic cases out of an estimated 100,000 etherizations. His conclusion was that ether rarely acts as an exciting cause of acute lobar pneumonia, and that the few cases of this complication may be classed as coincidences.

My own experience and that of other surgeons in the middle west with whom I have conversed on this subject, does not coincide with Prescott's statistics as to the relative frequency of lobar pneumonia after operations. Within two years I have had four undoubted cases in my own practice. The two just reported occurred out of 302 etherizations, of which 65 were for examinations and 237 for operations.

This brings up the question of whether the frequency of lobar pneumonia in my clinic can be explained by the nature of the anesthetic employed, its quality, or by the manner of its administration.

Ether is almost invariably employed as an anesthetic in the clinic, chloroform having been used only 17 times out of 319 anesthesias. The very best Squibbs' ether is used, so that the quality of the anesthetic can hardly be at fault. I have endeavored to perfect the technic of the administration of the anesthetic in the highest possible manner. An anesthetic chart is kept, showing the amount of ether used to render the patient unconscious, the total amount consumed during an operation and other data common to such charts. I personally see that the patient is not drenched with ether, and the anesthetizers are taught to attend strictly to their part of the work and nothing else. A good sign that the anesthetics have been administered well is that only twice has it been necessary to suspend an operation to revive a collapsed patient.

Particular care is taken at the clinic to avoid any unnecessary chilling of the patient during operation. Not only are the ordinary blankets employed, but such parts of the body as can be, are wrapped in cotton wool in order to preserve the body heat.

In order to prevent the hypersecretion of mucus so common during etherization, a hypodermic of atropia and morphia is given just prior to the anesthetic. If there be anything in the theory that the pneumococci find their way to the lungs through inspired mucus, as claimed by Whitney,[2] this danger is minimized by the

1. "Does Etherization Ever Cause Acute Lobar Pneumonia?" Boston Medical and Surgical Journal, March 28, 1895.
2. Boston Medical and Surgical Journal, Sept. 23, 1897.

action of these two drugs. I never hear in these days that distressing bubbling in the patient's throat. A tongue forceps, while always near at hand, is never employed, for the throat does not require swabbing.

The claim has been made, and perhaps justly, that the Trendelenburg position may be a factor in the production of pulmonary complications. That it impedes respiration during the operation, especially in fleshy patients, is a matter of common observation. The diaphragm is pressed towards the thorax by the viscera, which seek this position through the force of gravity or are crowded upward by the hands of the operator, who retains them in this unnatural position by gauze packs. It has been my custom for some time to modify the Trendelenburg position by partially elevating the head of the table after the intestines have been removed from and held away from the pelvis by packs. In this way one secures all the advantages of the Trendelenburg position while eliminating some of its disadvantages. The etiology of post-operative pulmonary complications, especially pneumonia, is obscure enough at best, and it behooves us to employ every means of prevention at our command.

It has been claimed that pneumonia is more apt to occur after abdominal than other operations. This is especially true if ether be the anesthetic employed. The statistics of Gurlt,[3] compiled from 52,677 anesthetizations, show that fewer deaths can be attributed directly to the use of ether than to chloroform or the mixtures. Pneumonia, however, is especially liable to occur after ether narcosis. Out of thirty such cases following ether narcosis, there were fifteen deaths. Thirteen of these occurred after abdominal operations. The explanation, according to Gurlt, lies in the suppression of the cough because of abdominal pain and tenderness.

As regards the so-called septic form of pneumonia, I believe that the term is too loosely applied. There is undoubtedly a hypostatic form of pneumonia which develops usually at the base of the lungs of a patient with peritonitis or other forms of sepsis. This hypostatic pneumonia differs not at all from that seen in other febrile conditions. The higher and longer continued the fever, the greater is apt to be the involvement of the lung. Another form of pneumonia arising from septic conditions elsewhere in the body is due to the lodgment of septic thrombi in ramifications of the pulmonary artery. Catarrhal pneumonia may surround the abscesses produced by the thrombi, and the fusion of these will give rise to areas of consolidation of the lung tissue. The diagnosis, however, of pneumonia of this description is not difficult, because of the accompanying signs of sepsis.

I am convinced that I have overlooked many cases of pleurisy, with or without effusion, in my operative cases in past years because of failure to make careful stethoscopic examinations where thoracic pain is complained of. In cases of moderate abdominal or pelvic sepsis, accompanied by pain and tenderness low down in the abdomen, it is a common error to ascribe pain higher up to these causes. More often are directions given to extend the area of external applications than are careful thoracic examinations made.

The following case illustrates the sero-fibrinous form of pleurisy undoubtedly of septic origin:

Case 3.—*(Gynecologic Case 306.)—Vaginal Hysterectomy for Foul-smelling Submucous Polyp, the Size of the Fist, Projecting from External Os. Septic Vaginal Discharge. Sero-Fibrinous Pleurisy, Right Side. Recovery.*—The patient, aged 47, had flowed almost continuously for over a year. At entrance her hemoglobin was only 35 per cent., but was increased to 65 per cent. by the administration of iron and the control of the hemorrhage. Very little hemorrhage and no shock accompanied the removal of the tumor and uterus by the vaginal route (Nov. 12, 1902). There was some absorption from suppuration of the vaginal stumps, but at no time were the symptoms alarming.

On the fifth day following the operation the patient complained of sharp pain in the right axilla, increased by forced inspiration. Examination of the affected area revealed to and fro friction sounds and established the diagnosis of pleurisy. These signs were followed by those of a pleuritic effusion. The condition gradually subsided under the appropriate treatment.

Here was an undoubted case of pleurisy of septic origin, the micro-organisms passing upwards to the pleura from the septic focus in the pelvis by way of the lymph channels. Streptococci have been found in the fluid of such pleurisies. The fluid may be either clear, cloudy or purulent, according to the nature and virulence of the infection. Purulent pleurisies as complications of scarlet fever, measles and typhoid, are not uncommon. Sears quotes Betke as having found 58 instances of pleurisy as a complication out of 1,420 cases of typhoid.

The following case shows double septic pleurisy where the diagnosis was confirmed postmortem:

Case 4.—*(Gynecologic Case 131.)—Bilateral Salpingo-Oophorectomy for Hydrosalpinx and Pyosalpinx in a Patient with General Miliary Tuberculosis. Bilateral Septic Pleurisy with Effusion. Death on the Fifth Day from General Suppurative Peritonitis. Autopsy.*—The patient, a frail girl of 22, had been ill for some months with signs referable to the pelvis. There was considerable operative shock, but she rallied under active stimulation. Septic symptoms developed almost immediately after the operation and resulted in death from peritonitis on the fifth day.

The day following the operation the patient complained of severe pain in the right chest and shoulder. The next day the pain was worse, although careful examination of the chest gave negative results. Within the next twenty-four hours pain had developed in the left thorax and to and fro friction sounds could be made out just below the fourth rib on the right side. The following day friction sounds could be heard over the left thorax.

The autopsy showed general suppurative peritonitis, general miliary tuberculosis and double pleurisy, more extensive on the right than the left side. There was a slight amount of cloudy fluid in each pleural cavity.

An interesting feature of this case was the difficulty in differentiating between beginning pneumonia and sepsis before the signs of both conditions became clear. There was at first very little abdominal pain and tympanites. The pulse was not particularly rapid nor thready, nor was the temperature markedly elevated. It was thought at first that she might be developing a lobar pneumonia until the ordinary signs of beginning general peritonitis appeared and were followed by an ever increasing pleuritic inflammation.

In still another case did a pleurisy develop after operation. Here, however, it is extremely doubtful whether it was due to sepsis.

Case 5.—*(Gynecologic Case 100.)—Abdominal Hystero-Salpingo-Oophorectomy for Chronic Disease of the Uterus and Appendages. Left Sided Dry Pleurisy on the Fourteenth Day After Operation. Recovery.*—The patient, aged 40, presented the usual symptoms of chronic disease of the uterus and adnexa. There was no history of previous pulmonary disease. Operation Jan. 17, 1902, unattended by shock.

For two weeks the patient's convalescence was uninterrupted, the wound healing by first intention. On the fourteenth day

3. Annals of Surgery, 1896, vol. xxiii, p. 232.

she was seized with a sharp pain over the left thorax, increased by forced inspiration. Examination was at first negative. Friction sounds were obtained two days later. While the temperature was but slightly elevated, the highest point reached being 101, the pleuritic complication was excessively annoying. There were no signs of effusion, and the patient made a good recovery.

Possibly in this case the pleurisy was tubercular, the lighting up of some old focus, as it is conceded that the majority of pleuritic inflammations are due to this cause. It is hard to ascribe it to septic absorption, as there were absolutely no septic symptoms in the case.

Case 6.—*(Gynecologic Case 70.)—Hystero-Salpingo-Oophorectomy for Chronic Disease of Uterus and Adnexa. Bronchitis Following Operation. Recovery.*—The patient, aged 46, was operated on Dec. 6, 1901. Considerable shock attended the operation. There was prompt reaction to stimulation. The following day there was a troublesome cough and complaint of oppression and pain in the chest. Examination the following day showed bronchial râles in abundance. The expectoration at this time was profuse and muco-purulent in character. The pulmonary symptoms subsided gradually under treatment. It was learned on inquiry that the patient had a cold just prior to the operation, but had not mentioned it.

I have recorded this case, not because it exhibited any alarming symptoms, but because such a bronchitis is not uncommon after ether narcosis. Under ordinary circumstances, even in the presence of a mild pharyngitis and laryngitis, the conditions present in an ordinary cold, I do not believe it is especially dangerous to administer ether. A slight increase of the irritation will be the only result, as a rule. But one is not sure of not having the grip germ present in the upper respiratory passages at certain times of the year, and experience has shown how deadly this organism is at times. The pneumococcus often found in the pharynx may not gain entrance into the system during a mild inflammation of the upper air passages, but when to this is added the irritation of the ether, it may actively flourish and place the patient in extreme peril.

For these reasons I am having more and more careful physical examinations made of patients prior to the narcosis and unless the operation be one of emergency it is postponed in the presence of even a slight cold.

IODOFORM DERMATITIS.

W. A. BRYAN, A.M., M.D.
ADJUNCT PROFESSOR OF SURGERY, VANDERBILT UNIVERSITY.
NASHVILLE, TENN.

It is the purpose of this paper to notice a phase of action iodoform sometimes assumes in the form of a dermatitis. By the term local iodoform dermatitis I have meant to distinguish this process from that showing constitutional involvement and an eruption scattered more or less over the body. This general involvement is well understood, but the purely local condition has been but little written of, and is probably not generally recognized as being produced by the application of iodoform, even when it does appear. My reason for calling this local iodoform dermatitis is the fact that it comes only on the surface surrounding the wound to which iodoform has been applied, produces no eruption or discomfort elsewhere and shows no special constitutional symptoms.

THE CLINICAL COURSE.

The appearance of the surface begins to change toward the end of the first 24 to 48 hours after application to an open wound, and resembles very much the poisoning of *Rhus toxicodendron,* with the exception that there is usually not so much redness present in the iodoform poisoning, for it is obscured by the vesicles that form on the skin. Numerous small vesicles appear around the point of application and increase gradually in the area they cover, until they may extend several inches from the focus. The vesicles toward the focus grow larger than those at the periphery because they are closer to the poison and get more of it. Often a number of vesicles coalesce and produce blebs of considerable size, which rupture and allow the contained serum to escape. Once the epithelium is broken the liberation of serum is more abundant in these than in any other lesions I have ever seen. In a few hours dressings are completely saturated with serum. The dressings thus stick closely to the wound, unless it is covered with an unguent. On removal of the cuticle the true skin appears as a thick, red, raw, edematous, uneven surface, often filled with little pockets of serum, resembling vesicles, but for the absence of the cuticle.

In a few instances the skin on which the blebs appear seems to be inflamed beyond the limits of vesiculation, but the majority of the cases I have seen have been devoid of such manifestation.

This eruption is likely to be mistaken for some other lesion, unless we remember not only its possibility, but as well its comparative frequency, and that it comes from iodoform no matter in what manner it is applied or to what surface. I have seen it come from the powder and the gauze, from application to the mucous surface and the skin. I have seen it called infection or eczema and treated for such, growing worse all the time.

The spread of iodoform dermatitis does not seem to follow any very definite rule, the usual method being by uniform extension in every direction. I have seen a case due to application to the stump made by enucleating an eye, spread upward over the brow and downward over the upper part of the face. Another case, the photograph of which is here presented, began at the metacarpophalangeal joint and extended up on the dorsum of the hand and down the dorsa and sides of the fingers. I saw another case with lacerated scalp have the whole side of his head above and below, in front of and behind the lesion, covered with ruptured, weeping vesicles. This fact seems to indicate that the spread of this process is through the connective tissue spaces rather than the lymphatics, as I at first thought.

The chief symptom complained of by the patient is an intense, intolerable itching; this symptom frequently begins before any change can be observed in the part complained of. It is incessant and described as a burning pain. Tenderness and irritability are other symptoms worth mention. These patients suffer intensely if great care is not used in removing dressings.

The duration of iodoform dermatitis is from one to four weeks under treatment, with removal of the cause. If iodoform is continued on the wound, in consequence of a false diagnosis, as that of infected wound, where iodoform is certainly a very useful drug, the symptoms will continue worse and worse until, from disgust, the surgeon tries some other drug.

How important must it be, then, that we recognize iodoform dermatitis when we see it, for, in the first place, almost any surgeon who uses iodoform in infected cases, having confidence in his drug, would increase the dose, and so increase the poison. Again, every patient who suffers once from this trouble ought to be told frankly by his surgeon that he has an idiosyncrasy for iodoform, that it poisons him, and in case of receipt of

another injury he should tell the attending surgeon of this fact.

The idiosyncrasy for this drug is peculiar in some respects. I have used the very best make of the drug I could find. In one instance a patient was treated with it without harm; shortly after his recovery he received another wound, which became infected, and on applying iodoform from the same bottle to it a typical case of dermatitis resulted. The patients who have, under my observation, developed this condition are usually of a sallow, unhealthy appearance, and somewhat anemic; but it is not confined to this type. I have seen only two or three cases developed in negroes, the failure to see any at all until recently having led me to believe it was not possible in them; but one case of a severe nature, that I saw recently, developed in a male negro, aged

Figure 1.

21 years, who had suffered from indolent ulcer of his leg for four or five months. I have been able to find one case, a trained nurse, on whose hand the vesicles would form if she even dressed a patient who was having iodoform applied, whether she came directly in contact with the drug or not.

The poison does not seem to be simply the iodin liberated. I have used iodin on as many cases as I have iodoform, yet not one of them has shown this vesicular type found consequent on iodoform. Iodin blisters many people very easily, but produces this blister under the cuticle, which, when it is peeled off, leaves a smooth, raw surface, not one showing irregularities like that from iodoform. Beside, iodin is limited in its action to the site of application, while the vesicles due to iodoform cover a wide area surrounding the original lesion. Again, the blister made by iodin, when it is opened and the cuticle taken away, does not tend to discharge serum indefinitely; the vesicles once ruptured in iodoform dermatitis, this discharge occurs without exception and is frequently very difficult to control. Iodoform seems to produce its effect by spreading through the cellular tissues of the skin; iodin by acting only on the surface. Recently I saw this same lesion produced by aristol.

Figure 2.

Figure 3.

ILLUSTRATIVE CASES.

The description made above will be better understood by the study of accompanying cuts.

Figure 1 represents a case of iodoform dermatitis 44 hours after the first and only application of iodoform made to the stump left by enucleation of the patient's left eye by Dr. G. C. Savage. This case suffered no rupture of the vesicles and was well at the end of one week from the beginning of treatment.

Figure 2 is iodoform dermatitis 72 hours after an only application of iodoform to an infected laceration marked A. A large bleb is seen at B and surrounding this are the small vesicles C. The case was as follows:

J. W. G. came with slight laceration on dorsum of left hand, July 18, 1901. This was cleansed antiseptically and was treated with no application, except bichlorid dressing for four days, when a little pus appeared. It was then dressed with sparing applications of iodoform of the very best quality from a box, out of which I had used half the contents on other cases with no harmful result. He returned after forty-eight hours for another dressing, at which time the peculiar form of local iodoform poisoning shown in the cut was apparent. The blisters were clipped and carbolated vaselin applied every day.

Figure 3 shows an advanced stage of the process, eight days after the application was made (March 4, 1901) to the infected laceration of the fourth and fifth fingers and of the dorsum near the base of the index finger shown at points A—A. The first succeeding dressing was March 6, 1901, when the patient complained of considerable itching of the parts. On examination, several blisters, which surrounded lesions and contained a yellowish serum, were noticed. The iodoform was thoroughly washed off, but too late to prevent the dermatitis. The process continued until at its worst the hand appeared as this picture shows it. The points B—B are the dead but as yet unseparated epithelium; C—C are red inflamed areas where the epithelium has come away; D is a wart, having nothing to do with the disease. The chief characteristic of these wounds is their abundant exudation of serum. Notice in the region devoid of epithelium, the small granular bodies; they are accumulations of serum in the skin proper. This photograph was taken March 14, 1901, just eight days after first appearance of blisters and ten days after application.

TREATMENT.

The treatment of iodoform dermatitis is, in the first place, to stop the application as soon as the first symptom of itching is complained of and the first little vesicle seen; cleanse the surface thoroughly, using peroxid of hydrogen to loosen up the iodoform that has adhered to it, remove every particle of the drug, for any part of it left acts continuously as a poison and delays recovery. After cleansing, daily applications of carbolized vaselin 5 per cent., or an aqueous solution of carbolic acid, should be made until all vesicles disappear. I have obtained better results from this application than from any other. It is well at each dressing to immerse the part in an astringent solution in hot water for from 10 to 30 minutes. If dry dressing or dusting powders are used, they must be applied freely and repeated frequently, as they become early saturated with the exuded serum.

CELL IMPLANTATION IN THE PRODUCTION OF TUMORS.*

From the New York State Laboratory, Buffalo, N. Y.

LEO LOEB, M.D.

MONTREAL.

The problem of the origin of tumors is a part of the physiology of growth. In explaining malignant tumors pathologists made use of two of the most obvious instances of ordinary tissue growth, namely, embryonic development and regenerative phenomena. Accordingly two theories have been advanced to explain tumor growth. The first one explains tumors as originating from embryonal cells, either actually detached from their normal surroundings, or at least functionally detached. With or without changing their place these cells do not take part in the further development of their neighbors; they remain in an embryonal condition, are not functionally active as the normal surrounding tissue is, until at a later period they begin to make use of their latent, stored up forces. Being locally or functionally disconnected they do not find the tension of the neighboring cells opposed to them and they can now grow indefinitely. This is, in the main, Cohnheim's theory, especially as it has lately been further developed by Wilms. This theory, therefore, combines the two factors named above. It makes use of the embryonic character of the tumor producing cells, and of the fact that these cells are disconnected, implanted, as it were, in a strange environment. The lack of the normal tension or the regenerative factor of growth is added to the embryonic factor.

Some clinical facts seem to support this theory. Many teratomata can hardly be explained any other way. Many mixed tumors suggest such an explanation as to their origin. There seem to be tumors representing transitional formations between the teratomata on the one side and simple tumors, like sarcoma, on the other side. But it is difficult to explain many tumors, especially many carcinomata, on this basis. Therefore, Ribbert, though accepting the first theory as sufficient for many cases, added a supplementary theory, making solely use of the regenerative factor for the explanation of tumors. Through inflammatory processes adult cells become separated from their normal ground. Cells which are no longer subjected to the inhibiting influence of their neighboring cells begin, as ordinary wound healing shows us, to grow, until they find their normal connection with cells of the same kind. Cells which are perfectly detached from their normal ground will probably never find their normal environment producing the necessary tension and will therefore be able to grow indefinitely.

After having thus defined the two factors underlying these two theories, we have to consider how far these conceptions really adequately explain the growth of tumors.

The first problem to investigate is: how do displaced embryonic cells actually behave? A number of facts have been ascertained through experiments carried on in the last twenty, and especially in the last ten years, which to some extent enable us to answer this question. Still, our knowledge is yet limited, especially because some facts have been found in certain species of animals only, and in applying the results of these experimental facts we have to do it with this restriction. Let us first consider what becomes of the earliest embryonic cells, whose normal relation to their neighboring cells has been disturbed. If one-sided pressure is exerted on the segmenting cells of the egg of a frog, e. g., so that the normal succession of cleavage is altered and the relation of the first cleavage cells to each other is different from their ordinary relation, a normal embryo ultimately results. If the first blastomeres are entirely separated from each other each one develops a normal though smaller embryo, the number of cells formed being proportionately smaller, their size remaining unaltered. This holds good absolutely only up to the four-cell stage; isolated cells from the eight and sixten cell stage still begin the normal development, and some of the blastomeres of the eight-cell stage run through the whole course of their development, but the blastomeres derived from these later stages stop at an earlier stage of their development. Thus the blastomeres derived from later stages differ in their fate from earlier blastomeres, not

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Pathology and Physiology, and approved for publication by the Executive Committee: Drs. Alfred Stengel, L. Hektoen and Frank B. Wynn.

as was to be expected by the former developing more specified parts of the whole, but instead, they form the first stages of whole embryos. No conclusive experiments have been made with regard to the fate of isolated blastomeres of later stages. Sufficiently large pieces of blastulæ also can develop perfect larvæ. At a somewhat later stage certain parts of the embryo must be present in the cut-out piece if the gastrulation shall take place. A certain morphogenetic localization has perhaps already taken place at this stage. Very few data are at hand for later stages. The observation of Roux, however, might be mentioned, who found very frequently in frog embryos with a closed medullary canal, isolated cells of the character of the much earlier morula stage.

Of importance are the recent experiments of Spemann. He found in triton at a stage when the medullary plate is already indicated, that by tightening a ligature across the medullary plate the anterior end of the posterior part will form a head just as the anterior part will do. We see that under these changed conditions ear vesicles can be formed from parts which, if the development would have proceeded normally, would not have formed any part of the head. That, however, does not yet prove that any isolated cell of an embryo at this stage is able to form these structures, but probably the connection of these cells with a large part of the embryo is necessary for this result.

Before drawing any conclusions from these experiments with regard to tumor formation, the results of experiments of a different kind shall be reported. Pieces of the tissue of embryos of different age were transplanted or injected into adult animals. At variable periods afterwards the fate of these pieces was determined. The following result was obtained: Most tissues grow and may even undergo a certain differentiation, corresponding probably (but how far that holds good has not been determined) to the differentiation they would have undergone normally. In some instances, where especial attention was given to this point, it was found that only a part of the transplanted tissue survives, that most of it degenerates and that the succeeding growth takes place from the surviving elements. The rate of growth is different for different tissues; it is most pronounced in the case of cartilage, but other tissues also grow, and epithelial cells may even arrange themselves in glandular form, even if they have been injected at such an early embryonic stage that no differentiation of this kind has yet taken place. Even glandular epithelia with granules characteristic for gland activity may develop. Ultimately, however, all these cells cease to grow and become resorbed. (Nevertheless, it is still to be determined whether certain cyst-like epithelial structures may not remain stationary, indefinitely, without becoming absorbed.) If we inject, instead of embryonal tissue adult tissue the result is, on the whole, the same. Of course, no differentiation comparable to the embryonic development takes place. Transplanted adult cartilage grows markedly less than embryonal cartilage. But a similar difference between the growth of adult and embryonic tissue does not seem to exist with regard to other tissues. In some cases adult cells even seem to grow better than embryonal cells. Further investigation into this question is needed. The data at hand at present do not justify the widely accepted idea that all embryonal transplanted tissues are much superior in their faculty to grow to adult tissues.

Let us now consider what conclusions might be drawn from these facts with regard to the formation of tumors. There are tumors consisting of a number of different tissues, with a limited growth, more or less resembling an irregularly formed embryo. Such teratomata might be derived from a detached blastomere, undergoing afterwards an autonomous development. Also Spemann's experiment might help us to explain certain tumors of a similar complex character. A wound or tear in the embryonic tissue of a later period might give rise to unexpected "heterotopic" formation, as e. g., to a brain-like tumor, at the caudal part of the spinal column.

But already here we find difficulties. In the first place we find these complicated tumors, although not exclusively, still in the majority of cases in the ovary and in the testicle. The explanation advanced to meet this difficulty is not sufficient and not quite satisfactory. In this connection it may be added that also mixed tumors of a less complex kind are, although not exclusively, mainly found at a few places, and again especially in glandular structures like the kidney, the salivary, lachrymal glands, and, to judge from recent findings, also in the thyroid gland. Roux observed early embryonic cells in different parts of the frog, not only in the "Anlage" of the genito-urinary organs; but, to my knowledge, just in the frog where such aberrant cells seem to be of a relatively frequent occurrence, teratomata or malignant tumors have never been described.

Nevertheless, the origin of this kind of tumors from blastomeres is the most probable one, although it must not be forgotten that it remains a mere hypothesis at present. Our knowledge does not seem to me to warrant us to exclude with an absolute certainty the older view of Waldeyer as to their possible origin from germinal cells, nor the hypothesis of Pfannenstiel as to their origin from ova. Mammalian ova may, in the beginning of the atresia of the follicles, show the first stages of segmentation. This segmentation is under the given conditions irregular, but irregular, also, is the segmentation of the ova of sea urchins in Hertwig's and Morgan's experiments. We must hesitate to exclude merely from data supplied by descriptive embryology possibilities which might be realized under conditions different from the ones under which the normal development takes place. Observations on the ordinary embryologic development would not have admitted the possibility of the development of isolated blastomeres to full embryos or of the formation of a typical lens from the retinal part of the iris in an adult organism. But there is a second difficulty. The growth of detached or separated embryonal cells leads, according to the above reported experiments, to a definite, limited growth. These embryomata, however, may start to grow like a malignant tumor, indefinitely, and may produce metastases. This also holds good of certain of the less complex mixed tumors, which otherwise might, in part at least, be explained as derived from detached embryonic cells or tissues of a later, already more differentiated type.

That leads us to the further consideration, can malignant tumors be explained by the detachment of cells, embryonic or adult? Malignant tumors grow apparently indefinitely; they may penetrate the surrounding tissue. Cells detached from the main tumor may, if they are not destroyed in the beginning (which probably frequently happens), multiply rapidly and form metastases. We saw that detached or transplanted normal embryonic or adult cells behave quite differently in the large number of experiments made. There is only one apparently divergent result published, the experiments of Lack with the scrapings of the ovary of a rabbit. That this apparently different result is due to an erroneous interpretation has been made very probable by Shattuck. How-

ever, it might be objected that there exist all degrees of malignancy. There really do exist tumors with different degrees of energy to grow. It has further been maintained, especially by Lubarsch, that the formation of metastases does not principally depend on the energy of growth of the tumor cells, but on a constitutional factor in the individual affected by the tumor (the capability to resorb transplanted cells being diminished). The transplantation of sarcoma and carcinoma, which has now succeeded in a sufficient number of cases, demonstrates, among other facts, that these objections do not hold good. The formation of metastases is caused by a primary increase in the energy of growth of the tumor cells. The transplanted cells rapidly multiply in a very large number of individuals of the same species. Secondly, transplanted tumor cells continue to multiply apparently without end, and therefore the difference between the transplantation of tumor cells and of ordinary embryonic or adult cells is very striking. With the tumor cell we seem to transplant some so far unknown factor which causes the cells to multiply without end. Different tumors have a varying energy; but this varying energy remains about constant in the same tumor in the course of a long series of succeeding transplantations. If we transplant pieces of a benign tumor, the transplanted cells remain benign. And even when we cut out pieces from such benign tumors at different intervals, the tumor did not, in the experiments made, assume a malignant character. On the other hand, transplantation of hypertrophic granulation tissue into different animals of the same species from which the original tissue was derived, was rapidly absorbed.

If Cohnheim in his lectures still maintained that experimentally transplanted cells may produce tumors, that, however, transplanted pieces of real tumors did not give rise to new growths—to-day we must reverse this statement. Neither the regenerative factor alone is able to change ordinary cells into cells of a malignant tumor, nor the embryonic character of the cells added to the regenerative factor. The results of experiments carried on from different points of view and with different methods corroborate each other. Ordinary embryonic cells, transplanted, have, under conditions, created experimentally only a limited growth. Therefore, we have no reason to assume that the results obtained so far are due to some accident and might be reversed some day. Still, there are factors which have perhaps not yet received the attention they deserve, e. g., the soil into which the tissues are transplanted, although a few investigations have been made into the question of the influence of the soil. It has recently been stated that tissues transplanted into ovaries had a more pronounced growth than those transplanted elsewhere. There does exist, however, another factor of more general significance. In the experiment of Spemann previously mentioned, embryonic tissue of triton could at many places produce a head, where, in the course of normal development the same tissue would have given origin to other organs. A head has, however, never been produced by injection of embryonic tissue. It makes some difference if the regenerating, detached, embryonic cells are on one side still in their normal connection with the rest of the body. It may be that the quantity of the regenerating substance has something to do with the different tissues regenerated by apparently the same cells, as especially Morgan suggests in some other connection. It may be that other correlative factors, perhaps of a specific chemical character, are here at play. There are other facts perhaps to be explained in a similar way. Pieces of hydra grafted to each other form different organs, if, after the union has taken place, both pieces remain of about the same size or if a large piece is cut off from one of the pieces. Perhaps also the fact that epithelium transplanted into epithelium has a different fate from epithelium transplanted elsewhere may belong to a similar category. The theories based on the supposition of detached, either embryonic or adult cells, as the cause of tumors, are at the present state of our knowledge not sufficient to explain the growth of malignant tumors. If transplanted epithelium enters into the normal union with connective tissue, the expansive growth of the epithelium will soon be arrested under formation of small cysts. If, however, such a regular union does not take place, the epithelium after a preliminary growth soon degenerates and connective tissue penetrates it. Decrease of tension added to sufficient nourishment is therefore not able to induce such epithelium to indefinite expansive growth, although such epithelium transplanted into blood serum, e. g., reproduces a number of the morphological appearances of carcinoma. Nevertheless, many, or perhaps most cells have a faculty for growth which is apparently almost indefinite, with regard to the quantity of tissue which can be produced and perhaps also to the time over which such growth can extend under favorable conditions. Why the transplanted tissues after a preliminary growth cease to continue to grow we do not yet know. Perhaps exhaustion of reserve material in the cells is the cause, perhaps some other factor plays a part. If we shall be able to experimentally prolong and increase the growth of transplanted tissue we will be nearer an understanding of the factors underlying the tumor growth.

The deficiency of the theories discussed here was, it seems, also recognized more or less by their authors. Wilms admits that some other unknown factor may come into play to produce a malignant tumor, though at other places the fact that the growing embryonic cells do not grow in their normal relation with neighboring cells seems to be sufficient to him to explain the boundless growth. Ribbert mentions "accommodation" of certain cells to the conditions of their new environment as necessary for their transformation into tumor cells. Israel, who applies similar principles as Ribbert, modifying them, however, in such a way as to include carcinomata arising from the surface epithelium directly and not from implanted cells, makes use of an hereditary transmission of an acquired increase in the energy to grow. Also Adami, in his theory which otherwise is based on different principles, makes use of an acquired "habit to grow." These or similar factors are perhaps not yet well defined, but they may be accessible to an experimental analysis. In this connection some recent experiments of Lyon might be mentioned, in which he succeeded in proving that an acquired immunity against potassium cyanid may be transmitted to succeeding generations of cells.

At the base of the theories discussed here lies a principle mainly gained by deductive a priori reasoning which was clearly expressed, especially by Weigert. This principle says that there do exist functional Reize (exciting causes), but no formative ones. All cell growth is caused by removing the tension of the neighboring cells. This theory itself is based on a theory of development, according to which no interdependence between normally developing parts of an organism takes place and all regenerative processes are caused by the presence of a reserve idioplasma called into action by removing the tension of the neighboring tissue. This

principle is a negative argument in favor of Cohnheim's and Ribbert's theories, excluding as it were the possibility of any other explanation for cell division. More promising, however, than the discussion of the above stated principle seems to be, at least with regard to the tumor problem, an analysis, and especially an experimental one, of the facts of embryonic development and of the regenerative processes. The latter must be an individual one for the different tissues which may behave differently. And here new methods must be worked out for new problems which suggest themselves. As Herbst and Spemann made it very probable that the touch of certain parts of the optic vesicle caused the skin of the head (and probably any part of the skin of the head) to form the lens, so G. Wolff demonstrated recently that the regenerative growth of the cut-off extremity of a triton does not take place if the medulla and the spinal ganglia are removed. In these cases we certainly can not speak of a removing of mechanic tension as the cause of growth. If the meaning of the removing of tension does not restrict itself to mechanic tension, it would be only used in a metaphorical sense and might mean any change of a chemical or physical nature; it would therefore essentially not be different in its meaning from the conception of a formative "Reiz." These causative factors for growth are at present still mostly unknown to us. Their analysis will also be necessary for a full understanding of the etiology of tumors. For even if micro-organisms shall have been definitely demonstrated as the cause of tumors, great as this achievement would be, the problem would still remain how such physical or chemical conditions created by the micro-organism can be the exciting factor of increased cell division.

DISCUSSION.

Dr. H. D. Pease, Albany, N. Y.—Before many of the phenomena observed in tumor formation and the production of metastases can be explained we shall certainly have to know more about the physiology of normal tissue elements, both embryonic and adult. Such questions lead to a discussion of the problems of cell division, tissue differentiation and inheritance. Even if it is eventually found that micro-organisms have an etiologic relation to malignant tumor formation, many of the phenomena which occur in such formations will require for their explanation a consideration of these problems.

REPORT OF A CASE OF TYPHOID PERFORATION WITH GENERAL PERITONEAL INFECTION

AND FIVE OTHER CONSECUTIVE CASES OF GENERAL SUPPURATIVE PERITONITIS; ALL RECOVERED.

J. B. MURPHY, A.M., M.D.
CHICAGO.

It is the prevalent opinion of the profession that practically all cases of general suppurative peritonitis should terminate fatally. That this is not true, however, is forcibly illustrated in the cases here reported. The questions arise, therefore: 1. What are the conditions which produce the fatal result? 2. Can these be overcome by medical or surgical treatment, and if so, when and how?

General suppurative peritonitis is not necessarily a fatal disease. The result of a general peritoneal infection depends on the following:

(*a*) *The type of infection.* If it be a virulent streptococcus type, with little pus formation, the peritoneum is rapidly denuded of the epithelial covering and becomes a "blistered surface" through which absorption rapidly takes place. Death in these cases is caused by the large quantity of the products of infection rapidly absorbed. If the poison be diluted or the pressure under which the infective products are retained be reduced the patient may pass over the critical period to a convalescence. If it be a staphylococcus or colon bacillus infection, the denudation of the peritoneum is slower, the danger of immediate overpowering of the patient by the absorbed toxins is diminished and the fatal termination is postponed often to four or six days, until such time as the fibrinous exudate which covers the peritoneum is exfoliated, taking with it the peritoneal endothelia. A rapid and fatal absorption may then ensue.

(*b*) *The period of time* that elapses between the infection and the time of operation. In the past the diagnosis of perforation was based on the combination of symptoms included under the term collapse, which was believed to occur a few hours after the perforation took place. At present the diagnosis of acute infectious perforative peritonitis is based on the symptoms of pain, nausea and vomiting, localized tenderness, circumscribed flatness on piano percussion, elevation of temperature and hyperleucocytosis, in the order mentioned. With these symptoms many of the patients give a history of diseased conditions which predispose to the development of perforative peritonitis. The operation should, therefore, be performed as soon as these symptoms are manifest. If it be postponed until the patient is in collapse the case will terminate fatally. If it be performed, however, in the early stage, the "peritoneal shingles" or endothelia will be found intact, thus preventing absorption. When these natural barriers to absorption are destroyed, as is the case when operation is delayed, a fatal termination can not be obviated.

(*c*) *The tension* under which the products of infection are retained in the peritoneal cavity. The mere pressure of pus in this situation does not necessarily mean absorption of the infective products. The greater the pressure under which the pus is held in these acute conditions the more rapid the absorption. This is true, not only in the peritoneal cavity, but also in suppurations in the cellular tissue in any portion of the body. Remove the pressure and there is an almost immediate cessation of absorption, as is shown by the sudden subsidence of the symptoms of infection after draining an abscess in any portion of the body, notwithstanding that pus remains in this cavity after it has been opened. The reduction of pressure is one of the basic principles of treatment of cases of general suppurative peritonitis. We believe, and have shown, that irrigation is not necessary in the peritoneal cavity any more than it is in circumscribed suppurations of other tissues.

(*d*) *The diffusion* of the infective material through the peritoneal cavity. It is well known that when this diffusion takes place in the upper half of the peritoneal cavity the danger is enormously increased, because absorption from this part is much more rapid than from the lower or pelvis portion. On this basis all patients were kept in the semi-sitting position, at an angle of thirty-five degrees, from the time they came under observation, both before and after operation, until the pus was entirely removed. In all the cases an effort was made to allow the pus to settle into the pelvis, where it would be free from pressure and could be easily carried off by the drainage tubes. In this way absorption took place slowly and the patients were saved from the primary, overwhelming dose of toxins, which is so fatal.

(*e*) *The administration of antitoxins and other substances* to antidote or dilute the immediate depressing effects of the poisons absorbed from the peritoneum. Antistreptococcus serum and unguentum Credé were administered to our patients, on the conviction that they contributed to this result to some degree. We believe that time is saved by their administration, in counteracting the effects of the poison, and the patient's chances for recovery are, therefore, increased. Saline transfusions were given some of the patients for the same purpose, as well as to increase the arterial tension when low.

(*f*) *The length of time the patient is kept under the anesthetic* and the extent of manipulation of the intestines and other tissues to which the patient is subjected during the operation. The patients were not killed on the table. I believe a large number of lives are sacrificed in operations for general peritonitis by excessive manipulation of the infected tissues and by sponging and irrigation of the peritoneal cavity. If the patient becomes severely depressed, collapsed or shocked on the table, it is practically certain that death will ensue; and, therefore, no operation which produces these conditions is justifiable. In all of these cases a general anesthetic was used, as it is my belief that sufficient time can be saved by working under general anesthesia to more than compensate for the dangers attending its use, and time is of vital importance in operations of this character.

The following report will illustrate the various phases of the individual cases:

Case 1.—Mr. J. D., aged 35 years, laborer. Admitted to Mercy Hospital, Nov. 18, 1902. Patient referred to me by Dr. D. Collins, with diagnosis of typhoid perforation.

Present Illness.—The patient was in the third week of a well-defined attack of typhoid fever and was progressing favorably. At 3 p. m. on the day of admission to hospital he experienced a sudden, severe, sharp pain in the umbilical region. Soon after onset of pain it became general over the lower half of the abdomen, he vomited and a considerable degree of tympany developed. When I examined him at 8 p. m. he was in the semi-sitting position and the abdomen was moderately distended and tender all over. On percussion there was tympany over the upper part, with dullness in the right flank and lower portion of the abdomen. The line of dullness changed with change in position of the patient. Dr. Collins' diagnosis of typhoid perforation was sustained and patient immediately sent to hospital for operation. In conveying him from his house to the hospital he was kept in the semi-sitting position on the stretcher and this position was maintained on the table throughout the entire operation. Ether was the anesthetic used. The pulse before beginning the anesthetic was 130 and respiration 30, rapid, shallow and entirely costal in type. There was, however, in this case, an absence of the symptoms of collapse. Camphorated oil, minims 10 and strychnia sulph gr. 1/30 were given hypodermically before starting the anesthetic.

Operation.—10 p. m. Incision below the umbilicus and through the right rectus muscle was made in opening the abdomen. As soon as the peritoneum was incised a large quantity of yellowish green fluid containing flakes of lymph exudate, welled out of the opening. This fluid was free in the peritoneal cavity and there were no adhesions. The entire peritoneal surface was deeply congested and covered in places with white patches of exudate. The luster and gloss of the membrane were, however, preserved. The caput coli was first sought and drawn out of the wound, and the ileum traced from here. On drawing the latter out it was found greatly thickened in places and its peritoneal covering showed the most intense degree of congestion and infiltration. About twelve inches from the ilio-cecal valve a perforation of the intestinal wall was found, 4.5 m.m. in diameter, through which the contents of the ileum were escaping. The perforation was in the center of an indurated, infiltrated, Peyer's patch, and there were no evidences of the formation of adhesions in the neighboring intestinal coils. The perforation was closed by a double row of silk Lembert sutures, introduced in the healthy tissue, well to the side of the infiltrated Peyer's patch. In this way the bowel wall was folded inward longitudinally, from each side, and it completely buried the ulcer, with the perforation in its center. When the suturing was completed the lumen of the bowel was considerably narrowed, but this was unavoidable, as any sutures introduced into the infiltrated tissue would have torn through After closing the perforation the coil was dropped back into the abdomen and the incision closed in separate layers, catgut for the peritoneum and fascia of the rectus and horsehair for the skin. The fluid was not sponged out. Two rubber drainage tubes, ½ in. in diameter, were inserted deep into the pelvis, and came out through the lower end of the incision. Through these tubes the pelvis was irrigated with normal saline solution and a large quantity of greenish fluid escaped. The pulse became very weak and rapid towards the end of the operation, so a quart of normal saline solution was given intra-venously. Time of operation, 27 minutes.

Patient was returned to his room at 10:40 p. m. and placed in bed in a semi-sitting posture at an angle of 40 degrees. This position was maintained for ten days. After he was put to bed his pulse was 140 per minute and weak. Camphorated oil, minims 10 and strych. sulph. gr. 1/30 were given hypodermically. At 11:30 pulse was 140, very weak, and respirations 40 per minute. A second intra-venous transfusion of 20℥ normal saline solution was given and hypodermics of: caffein gr. 2, camphorated ether minims 10, strych. sulph. gr. 1/30, and digitalin gr. 1/50, ordered every four hours. At 12 p. m. 10 c.c. of antistreptococcus serum was given hypodermically and the dose repeated at 3 and 6 a. m. He rested quietly during the night except when disturbed to take his medicine; passed urine freely. The pulse gradually became slower and stronger and by 8 a. m. was 100 per minute, with temperature 99 (Ax) and respirations 34. Wound was dressed and the dressings found saturated. Inunctions of ung. Credé were ordered daily. At 11 a. m. pulse again became weaker and he was given a saline enema, which was retained P. m. temperature 100.6, pulse 100. Saline enemata were repeated after this every five hours and water given freely by mouth after 6 p. m. the day following the operation; the urine showed albumin and hyaline and granular casts.

November 20, a. m., temperature 101.4, pulse 96, respirations 26. He had a good night and expressed himself as feeling well. He vomited several times during the day, complained of some epigastric pain and slept at intervals. The camphorated ether and caffein which had been given hypodermically every four hours were stopped, but the digitalin and strychnin sulph. were continued. His pulse during the day decreased in frequency from 100 in the morning to 86 at 6 p. m., at which time his axillary temperature registered 100.6 and respirations 28. 1,300 c.c. of urine was excreted during the 24 hours. Bowels did not move, and he retained his enemata. Urine still contained albumin and casts (hyaline).

November 21, a. m., temperature 99 (ax.), pulse 68, respirations 30. Patient did not sleep much during the night, but rested quietly. He vomited several times during the day and developed a slight cough, with moderate amount of expectoration. During the afternoon two low enemata were given at intervals of four hours, and produced slight bowel movement. P. m., temperature 101 (ax.), pulse 88. Digitalin stopped. Urine abundant.

November 22, a.m., temperature 99.6, pulse 76; p. m, temperature 100.6, pulse 80. Bowels moved freely. Slight cough persists and sputum blood tinged.

November 23, a. m., temperature 98, pulse 70; p. m., temperature 99.6, pulse 74. From this date pulse and temperature remained practically normal and patient convalesced rapidly. He sat up in chair December 8. Drainage tubes were gradually shortened and diminished in size as the discharge lessened, and

were removed altogether Dec. 10. He was discharged from the hospital with wound almost entirely closed December 12.

Case 2.—Mr. F. B. T., aged 26 years. Admitted to Frances Willard Hospital July 12, 1902.

Previous History.—Negative. Family history, negative.

Present Illness.—Three days previous to admission to hospital patient was attacked with severe pain in the right iliac fossa, accompanied by nausea and vomiting. Temperature reached 100 on the evening of the attack. The next day the pain was more circumscribed and remained so until the morning of the third day, when it suddenly became general over abdomen, and considerable tympanitic distension of the abdomen developed at the same time. It was decided that the patient had a perforation of his appendix, with general peritonitis. He was transported seven miles in a wagon to the railway station and four hours on train to Chicago. When he arrived here his pulse was 130 and temperature 101.5. Abdomen was much distended and flat on piano percussion in the flanks and lower portion. Leucocyte count on the evening of the third day showed 50,000 per cubic mm.

A diagnosis of perforative peritonitis was made, though the patient was not vomiting and not in the least collapsed.

Operation.—July 12, 1902. Abdomen opened by ordinary appendiceal incision through outer edge of right rectus muscle. When the peritoneum was opened pus with gas shot out, so great was the tension. The appendix was gangrenous and perforated. Appendix removed and large drainage tube inserted into the pelvis and right iliac fossa. No abdominal sponging or irrigation was used. There was no attempt on the part of the intestines or omentum to wall off the infective process. The bowel retained some of its normal gloss, but the pus was very offensive and the case did not look promising. Abdomen closed by figure of eight sutures of silkworm gut down to the drainage tubes.

Patient was placed in his bed in the semi-sitting position, at an angle of 35 degrees. Repeated saline enemata were administered and large quantities of fluid given by mouth immediately after the patient regained consciousness. The tubes were left in for two weeks, but during this time were gradually shortened as the discharge lessened. The temperature rapidly subsided to normal after the operation and the patient made an uninterrupted recovery. In this case, as in most of the others, inunctions of ung. Credé were given daily for one week. Anti-streptococcus serum was not given.

Case 3.—Mrs. K., aged 50. Admitted to Mercy Hospital Oct. 12, 1902. Family history negative. Personal history negative.

Present Illness.—After breakfast, October 9, patient was taken suddenly ill with severe cramping pain in umbilical region. Soon after onset of pain she became nauseated and vomited freely. Pain continued general over abdomen for sixteen hours, when it became localized to the right iliac region and vomiting, which had been persistent, subsided. She had fever during this time, but does not know how much, and was very tender to pressure in the appendiceal region. After 36 hours pain lessened, but soon afterwards reappeared and was severe. It was now general over the entire abdomen and not localized to the right side. I saw the patient in consultation with Dr. George W. Webster on the evening of October 12, and concurred in the advisal of immediate removal to the hospital and operation.

Operation.—October 12, 10:30 p. m. Usual appendiceal incision through the right rectus muscle into the peritoneal cavity. On incising the peritoneum pus welled out. There were absolutely no adhesions anywhere in the peritoneal cavity, and the pus was distributed everywhere. The appendix presented considerable swelling and was perforated near its base, the perforation taking place into the free peritoneal cavity. No fibrinous exudate was found on the intestines, and there was no effort at agglutination. After ligating the mesentery and appendix, the latter was amputated. Two large rubber drainage tubes, ½ inch in diameter, were inserted, one deep in the cul-de-sac and one in the right iliac fossa. The abdominal wall was closed with figure of eight sutures of silkworm gut. No irrigation was used and the pus was not sponged out. In this case the peritoneum showed considerable congestion, but the normal gloss was retained, showing that the endothelial covering was intact. Patient was put to bed in sem-sitting posture at an angle of thirty-five degrees. With each inspiration the pus welled out of the pelvis through the tubes. At 11:15 p. m. pulse was 120, and at 12 126, with respirations of 40. As soon as she was put to bed she was given strychnia sulph. gr. 1/20, digitalin gr. 1/50, caffein cit. gr. 2 hypodermically.

October 13, patient rested quietly during night and vomited only a few times. She took water freely and retained much of it; a. m., temperature 99.8, pulse 98; p. m., temperature 101, pulse 104. Hypodermics of strychnia and caffein were continued every four hours. Dessertspoonful doses of the infusion of digitalis were ordered every three hours to increase the secretion of urine, which was small in quantity and contained considerable albumin and many hyaline casts. Patient vomited only once during the day and took water freely.

October 14, patient had good night; a. m., temperature 99.2, pulse 98, respiration 30; p. m., temperature 99.6, pulse 96. Urine now abundant, no albumin present, but hyaline casts still numerous. About noon patient was given a saline enema and this was followed soon afterward by a slight bowel movement. She had two more small passages during the afternoon. In the evening the following prescription was ordered every six hours: Ox gall grs. 5, ex. belladonna gr. 1/20, ex. nux vomica gr. ¼, aloin gr. 1/10.

October 15, a. m., temperature 99.2, pulse 96; p. m., temperature 99.4, pulse 88. Patient expelled considerable gas from bowels, but did not have a free movement. Wound was discharging freely.

October 16, during the preceding 24 hours patient passed 1,500 c.c. of urine, which contained no albumin and very few casts. The infusion of digitalin discontinued, as were also the hypodermics of caffein; a. m., temperature 99.8, pulse 90; p. m., temperature 99.6, pulse 96. During the day patient had five bowel movements and passed a good deal of gas.

October 17, a. m., temperature 99, pulse 96; p. m., temperature 100.2, pulse 84. From this date until October 21 temperature in the evening ranged between 99.6 and 100.4, with pulse 88 to 96. The discharge continued quite profuse and was somewhat offensive. Bowels moved daily during this time and she complained but little of pain in abdomen. From October 21 to November 4 p. m. temperature ranged from 99 to 99.6, with pulse from 82 to 90. During this time the discharge decreased in quantity and the wound was dressed with gauze soaked in a saturated solution of sodium bicarbonate to overcome the offensive odor. She complained little of pain; bowels moved freely daily and urine was abundant. The drainage tube in the right iliac fossa was removed October 25 and the pelvic tube four days later.

November 4, patient complained of pain and tenderness in the left iliac fossa and her temperature on this date went up to 101 in the afternoon. The next day a tender induration was palpable in this region and it was evident that pus was here retained. Induration and temperature persisted until November 8, when the accumulation discharged spontaneously into the canal left after removal of the drainage tube. After this her temperature rapidly descended to normal and continued so. Patient sat up in chair November 8, and was discharged from the hospital November 23, with the wound almost healed.

Case 4.—R. G., male, aged 16 years. Referred by Dr. Anna Dwyer.

Previous History.—During past three years had been subject to frequent attacks of abdominal pain, at times localized in right iliac fossa; no severe acute attacks. Present illness began October 18, 1902, with intermittent abdominal pain, which continued until next afternoon, when he vomited Pain generalized at first, later localized in right iliac region. Cathartics were administered by attending physician, but were not retained. Vomiting continued for 18 hours, when it became less frequent; the pain, however, remained severe. At 4 p. m., October 20 temperature was 101.2 and pulse 100. A well-

defined mass was present in the right iliac fossa. The author saw the case at 9 p. m. and advised immediate operation, but to this the parents would not consent. The next day the abdominal pain had increased greatly in severity and was generalized over the abdomen. Simultaneously with the increase and generalization of the pain the tumor mass became much less clearly defined and diffuse tenderness developed.

Operation.—Performed 7:30 p. m., October 21. The usual incision was made through right rectus muscle, into the peritoneal cavity. On incising the peritoneum the pus welled out and was free in the peritoneal cavity; with no adhesions except immediately around the appendix. The peritoneum was intensely congested and covered in places with fibrinous exudate. The gloss was preserved except in certain areas, where the congestion was most intense. The appendix was gangrenous and perforated on one side into the free peritoneal cavity. A large fecal concretion was present. Appendix was amputated and stump buried. Two large drainage tubes were inserted—one into the pelvis and the other into the right iliac fossa. Abdomen was closed with separate layers. No sponging or irrigation used. Patient placed in bed in semi-sitting position at 37 degrees.

At 8 p. m. pulse was 152. Strychnia sulph. gr. 1/30 given and repeated every three hours. At 9 p. m. 10 c.c. anti-streptococcus serum given hypodermically, and this dose was repeated at 11 p. m. and 2:30 a. m. Inunctions of ung. Credé given at 9:30 p. m. and 2:30 a. m. At 10 p. m. temperature 103 (ax.), pulse 140, respirations 24. Up to this time had drank five glasses of water since coming out of anesthetic. Rested quietly during the night and vomited only once.

October 22, a. m., temperature 102.6, pulse 120, respirations 36. Dressings saturated with discharge from tube. At 10:20 a. m. high saline enema given and ordered repeated every two to three hours. Water given freely. P. m., temperature 102.6, pulse 120, respirations 34. Patient given small dose of saline cathartic at 2:15 p. m., which was followed at 4:30 by a slight bowel movement and again at 7:30 in the evening. No vomiting.

October 23, patient had good night. A. m., temperature 101.4, pulse 100, respirations 28. Had one good bowel movement and expelled a great deal of gas from the bowels, both spontaneously and after enemata; p. m., temperature 101.4, pulse 92, respirations 30; wound discharging freely.

October 24, a. m., temperature 101.4, pulse 88, respirations 30. Wound dressed and 1½ inch of upper drainage tube removed. The gauze drain, which was left in with the upper drainage tube, was loosened. P. m., temperature 101.4, pulse 84, respirations 26.

October 25, a. m., temperature 100, pulse 80. Wound dressed and a portion of the gauze drain removed. P. m., temperature 100.6, pulse 80.

From this date until October 31 temperature ranged between 100 and 101 in the afternoon, with pulse gradually lessening in frequency from 80 to 76. After October 31 it remained normal morning and evening. October 28 sutures and gauze packing were removed. November 4 drainage tube was entirely removed and discharge was very slight. Patient was kept in bed in the semi-sitting position until November 7, when he first sat up. After this date wound healed rapidly and he made an uninterrupted recovery.

CASE 5.—Mr. E. H., aged 19 years, occupation printer. Admitted to Mercy Hospital Oct. 25, 1902. Family and previous history negative.

Present Illness.—Began suddenly four days before admission with severe cramping pains in abdomen. Pain at first was more or less general and was followed after a few hours by nausea, vomiting and temperature of 102 F. After 24 hours the nausea and vomiting subsided, but the pain persisted and gradually localized in the right iliac region, where it remained for 72 hours. Temperature at this time was 101 to 102 F. At the end of third day the pain suddenly became more severe and spread over the entire abdomen. He had a chill, followed by profuse perspiration and the temperature rose to 103 F. When admitted to the hospital the next day, abdomen was moderately distended and extremely tender all over. Breathing was almost entirely costal and the abdominal muscles held so rigidly that deep palpation was impossible. On piano percussion there was dullness extending up almost to umbilicus. An absence of peristalsis existed all over the abdomen.

A diagnosis of perforative appendicitis with general peritonitis was made and patient at once prepared for operation.

Operation.—Ether anesthesia. The usual appendiceal incision made through the outer margin of the right rectus muscle, into the free peritoneal cavity, which was found to contain a large quantity of yellowish pus, possessing a slight odor. The appendix was gangrenous and perforated. A circumscribed abscess had ruptured into the peritoneal cavity. The intestines were everywhere bathed in pus, but though considerably congested, they still retained their endothelial covering. Appendix was removed. Perforated rubber drain, one-half inch in diameter, inserted into most dependent portion of pelvis, and also into right iliac fossa. The pus was not sponged out, nor was the abdomen flushed. Time of operation 20 minutes.

Patient returned to his room at 1:30 p. m. in fair condition, pulse 128. Placed in semi-sitting position at 35 degrees and kept there for six days. When he regained consciousness three pints of normal saline solution was given per rectum and was retained. Temperature at 5 p. m. was 100 (ax.). At 6:30 p. m. 10 c.c. anti-streptococcus serum was given hypodermically, and this was repeated at 9 p. m. and again at 12. A second enema of normal saline solution was given at 7 p. m. and retained. At 9 p. m. temperature was 101 (ax.), pulse 120 and respiration 34.

October 26, a. m., temperature was 101.8 and pulse 106; p. m., temperature 100.6, pulse 112. Water was given freely and most of it retained. He vomited only twice during the day and his bowels moved freely three times, after being started by an enema given in the morning. One quart of saline solution was given per rectum every four hours, and 20 minims nuclein hypodermically at the same intervals. Urine was passed freely.

October 27, patient complained of some pain across abdomen; wound was dressed and a large amount of sero-purulent discharge found on the dressing. A. m., temperature 100 and pulse 100; p. m., temperature 100.8, pulse 100. Inunctions of 40 grains ung. Credé ordered daily. Bowels moved freely and urine was abundant. Patient complained very little of pain in the abdomen and rested well.

October 28, a. m., temperature 99.8, pulse 88; p. m., temperature 100, pulse 86.

October 29, a. m., temperature 98.8; p. m., 99.4. Ung. Credé stopped and soft diet ordered.

October 31, wound dressed and very slight discharge found on dressing. Nuclein discontinued.

Highest temperature 99.4 in the afternoon.

Temperature reached normal November 2 and remained so until the 10th, when he developed a slight pleurisy, which caused an elevation to 100 for four days. It then again dropped to normal. Patient made an uninterrupted recovery, sat up December 2 and was discharged well December 10. Drainage tube was gradually shortened and reduced in size as the discharge lessened. It was removed altogether November 19.

CASE 6.—Mr. F. McC. Admitted to Mercy Hospital Nov. 8, 1902. Family history negative. Personal history negative.

Present Illness.—About one month before onset of present trouble patient had a well-defined attack of appendicitis, lasting four days and from which he apparently completely recovered. He worked steadily from that time until onset of present attack. About 3 o'clock on the morning of November 8 patient was awakened by very severe, sharp pain in abdomen, about umbilical region. Soon after onset he became nauseated and vomited freely. Bowels did not move. He had no chill and temperature was not above 100 F. Symptoms continued until 8 o'clock a. m., when nausea and vomiting disappeared. He walked to the hospital, and was accompanied by his attending physician when admitted. Pain was still severe and abdominal muscles rigid, especially on right side. Tenderness to pressure was general over abdomen, but not very acute. A

diagnosis of acute appendicitis without perforation was made and patient persuaded to have an immediate operation. He came in during a clinic and one-half hour afterward was on the operating table.

Operation.—Nov. 8, 1902. Usual appendiceal incision through outer border of right rectus muscle, into peritoneal cavity. To our great surprise, on incising the peritoneum, it was found full of free pus with some gas. Examination revealed a perforation of the appendix. The perforation had been capped with the omentum, but through some accident on the night preceding his admission the cap was partially torn from opening and the contents had escaped into the peritoneal cavity. The probe could be inserted into the lumen of the appendix; the peritoneum was not "blistered," and its gloss was not seriously disturbed. The lower half of the abdominal and pelvic cavities contained large quantities of pus. Appendix was amputated; two large drainage tubes were inserted into pelvis. With each inspiration pus welled out of the tubes.

Patient was returned to his room at 1:15 and placed in bed in semi-sitting position, at angle of 35 degrees. Pulse 104 when he recovered consciousness. He vomited small quantity of greenish fluid, was restless and complained of pain in wound. At 6 p m. pulse was 78 and temperature 99.4. At this time he was given ½ gr. calomel and the dose was repeated at one-half hour intervals until 3 grains were given. At 6, 8 and 12 p. m. anti-streptococcus serum was given hypodermically in doses of 10 c.c. He slept some during the night, vomited once after taking ʒii mag. sulph., and at 4 a. m. was given a high rectal enema, which produced a free bowel movement. 300 c.c. of urine was passed.

November 9, a. m., temperature 99.4, pulse 92; p. m., temperature 100.6, pulse 108. Nuclein solution M. 20 was ordered every four hours, and inunctions of ung. Credé gr. 45, daily, Towards evening patient was restless and slightly delirious. November 10, a. m., temperature 98.8, pulse 88. Good bowel movement followed high enema. Still quite restless and slightly delirious at times. Complains of some pain. P. m., temperature 99.2, pulse 90. Calomel was given in divided doses, followed by mag. citrate, ʒi. Bowels moved twice. Wound was dressed and moderate amount of discharge found on dressing. November 11, a. m., temperature 99, pulse 76. Patient resting much more comfortably and bowels moved freely. P. m., temperature 100, pulse 84.

November 12, a. m., temperature 98.6, pulse 82; p. m., temperature 99, pulse 82. From this date until November 20 temperature ranged from 99 in the morning to 101 in the afternoon. On November 20 it reached normal in the afternoon and remained there until his discharge from the hospital. The drainage tubes were kept in for ten days, the tube being gradually shortened and diminished in size from time to time as the discharge lessened in amount. Dressings soaked in a saturated solution of sod. bicarb. were applied to the wound when the discharge was profuse to overcome the offensive odor, which persisted for six or eight days. Patient left the hospital December 6 cured.

This case illustrates forcibly what I have taught for years: That there is little or no depression immediately after perforation of the intestine and no collapse. In other words, collapse is a late manifestation and is the expression of the "blistering" of the peritoneum and absorption of the products of infection.

In this patient's case absorption did not have time to occur, as he was operated on ten hours after perforation took place. It will be noted that this patient was walking about the street with his physician, with his abdomen full of pus and a direct opening from his appendix into the free peritoneal cavity. Neither did I suspect the condition when I examined him before the operation.

No Medical Advertisements to the Laity.—A peculiar provision of Spanish law is that pharmacists are prohibited from advertising medicines or remedies in any papers but journals of medicine, surgery or pharmacy.

FUNCTIONAL TESTS OF HEARING: SOME OF THE PRINCIPLES ON WHICH THEY ARE BASED.*

WILLIAM LINCOLN BALLENGER, M.D.
CHICAGO.

The object of this paper is to call attention to the value of some of the functional tests of hearing and to the principles on which they are based. Wm. H. Thompson has recently made the significant statement that a knowledge of diseases of the ear is of more value to the general practitioner than that of all the other special senses put together. This being true, a knowledge of the more accurate methods of diagnosis and prognosis becomes a question of prime importance. The functional tests of hearing are of greatest value in that large and oftentimes perplexing group of diseases of the non-suppurative type which affect the middle ear and labyrinth.

No one doing ear work can claim to be abreast of the times if he does not have an intimate and comprehensive knowledge of the principles underlying these tests. They are to the otologist what the ophthalmoscope is to the oculist, or the stethoscope is to the one skilled in diseases of the chest.

It has been a source of some surprise to me to hear otologists of good repute refer to the functional tests of hearing as being of very limited value for diagnostic purposes. I may be pardoned, therefore, for making the following remarks on this subject:

In order to place it more clearly before us for discussion I will first state the principles on which the tests are based.

First Major Principle.—The range of hearing in adults under 55 years of age is approximately 16 to 48,000 vibrations per second. After the fiftieth or fifty-fifth year the hearing for the upper tones is somewhat reduced, as has been shown by Zwardemaker, Bezold and others. The very aged do not, as a rule, hear tones higher than 37,000 vibrations per second. This should be borne in mind, as the case might otherwise be mistaken for one with labyrinthine deafness.

Under the first major principle may be grouped two secondary principles which only serve the purpose of elaborating or elucidating it. They are as follows:

(*a*) Anything which disturbs the normal tension of the drumhead and ossicular chain will diminish or abolish the hearing for the two or three lower octaves.

(*b*) Any disease affecting the perception apparatus will diminish or abolish the hearing for the upper tones of the range of hearing.

Second Major Principle.—Hearing by bone conduction is approximately one-half as long as hearing by air conduction.

This rule is subject to considerable variation in normal ears, but for practical purposes in the study of these principles we do not need to make a closer analysis. The point to be borne in mind is that hearing by air conduction is longer than by bone conduction.

The second major principle may be still further elaborated or elucidated by two secondary principles, namely:

(*c*) Hearing by bone conduction is increased in those affections of the middle ear which disturb the normal tension existing between the drumhead and ossicular chain.

* Read at the Fifty-third Annual Meeting of the American Medical Association, in the Section on Laryngology and Otology, and approved for publication by the Executive Committee: Drs. Emil Mayer, C. R. Holmes and G. H. Makuen.

(*d*) Hearing by bone conduction is diminished or abolished in affections of the labyrinth or perception apparatus.

Third Major Principle.—The intensity of hearing by bone conduction is either increased or diminished by morbid conditions within the middle ear or labyrinth. Two secondary principles may be given in this connection, namely:

(*e*) Any disturbance of the normal tension existing between the drumhead and ossicular chain will increase the intensity of hearing by bone conduction.

(*f*) Any disturbance of the perception apparatus will diminish the intensity of hearing by bone conduction.

With these principles in mind we are prepared to discuss their application to the purposes of diagnosis and prognosis.

After having made a careful history of the case, including all subjective and objective phenomena, it has been my custom in both clinical and private practice to test the range of hearing with tuning forks for the lower seven octaves, and with the Galton whistle for the remaining or higher limit of hearing. Note should be made as to whether the lower or higher tones are not heard. According to the secondary principles, *a,* if the lower tones are not heard middle ear or tubal disease is probably present. If the upper tones are not heard it is presumptive evidence of labyrinthine disease, as is shown in secondary principle *b*. Hence, the examination as to the range of hearing is of great value in determining whether the deafness is due to middle ear or to labyrinthine involvement. Thus, if a given case does not hear forks below, say 256 vibrations per second, we would be justified in assuming it to be one of middle ear disease; whereas, if the upper tones of the Galton whistle are not heard it is fair to assume that the labyrinth is involved.

There are exceptions to these conclusions, one being in those cases well advanced in years, when the upper tone limit is normally reduced; another is when there is marked retraction of the drumhead, forcing the footplate well into the oval window. The tension of the intralabyrinthine fluid is thereby increased, and may give the usual functional signs of true labyrinthine disease. The signs will quickly disappear, however, on inflation of the tympanic cavity, and thus clear the diagnosis.

As shown in the second major principle, hearing by bone conduction is approximately one-half as long as it is by air conduction. If, in a given case, bone conduction in the affected ear is relatively longer than hearing by air conduction, the disease is probably within the middle ear. If the Weber test is performed the sound will latteralize to the affected side; or if the Rinné test is made the result will be negative Rinné, i. e., hearing by bone conduction will be longer than by air conduction.

If, on the other hand, bone conduction in the affected side is relatively diminished in duration, it is probably one of labyrinthine involvement. The Weber tests will latteralize to the good or better ear rather than to the more affected side, while the Rinné and Schwaback tests will show a relatively diminished hearing by bone conduction on the affected side. In pronounced cases the hearing by bone conduction is entirely lost in the affected ear.

It is apparent, therefore, that a knowledge of the foregoing principles will render the functional tests of the organ of hearing comparatively easy to comprehend. It is easier to comprehend principles than it is to comprehend tests without a knowledge of the principles on which they are based. It is, therefore, well to group the tests under the principles which they elucidate. Thus, under the first major principle we may place the test for the range of hearing by the tuning fork and Galton whistle, making note as to whether the lower tones (subprinciple *a*) or the higher tones (subprinciple *b*) are lost.

Under the second major principle we may place the Weber, Schwaback and Rinné tests, as they show the relative duration of hearing by bone and air conduction.

Under the third major principle we may also place the Weber test, as it shows the relative intensity of hearing by bone conduction in the two ears.

And so we may classify all the functional tests of the ear under the various principles which they elucidate. Much confusion arises from a failure to comprehend the principles on which they are based, each test being used as an arbitrary or empyric method of determining the nature and location of the lesion causing the deafness. A better and simpler way to approach this subject is to first study the principles on which the tests are based and then group them according to the principle or principles they are supposed to explain. In this way the various tests and their individual and collective significance will afford a means of greater discrimination in the diagnosis and prognosis of many ear diseases which would otherwise be but partially understood.

There is not time within the limits of this paper to enter into a discussion of the relative merits or significance of the various tests. I wish to say, however, that it is rarely safe to draw conclusions from any single functional test. The composite of several tests, together with the history and clinical phenomena, should all be considered in making the diagnosis.

DISCUSSION.

DR. A. H. ANDREWS, Chicago—I think this is a good time to mention the importance of the entire subject of otology. I think that in most of the medical colleges of the United States it is a sadly neglected subject. I will say, further, that it does not seem to be the fault of otologists, but rather the fault of those who have the arranging of the curriculum of the various colleges that it is not given greater prominence. Medical students need not be specialists, but they ought to know enough to do something with diseased ears. The Doctor states that the relation between air conduction and bone conduction is approximately as 1:2. That is no doubt approximately true, but it makes a great difference on what part of the mastoid the handle of the tuning fork is placed. If it is placed immediately behind the auricle the patient will hear it much longer than if it is placed above or below. If the handle is pressed tightly against the mastoid he will hear it considably longer than if it is pressed lightly. All these things should be borne in mind in testing bone conduction. Another point is the importance of testing in the first examination both before and after inflation of the tympanic cavity. Sometimes the relation between air conduction and bone conduction will be reversed after inflation. In very many cases it will be materially modified. Not only is this important from the standpoint of functional examinations, but it is very important in making a prognosis. Further, in making tests of bone conduction we will sometimes find that one fork is not heard as well by bone conduction as another fork. I have often seen cases where the C 2, 512 vibrations was not heard as long as a higher fork or a lower fork. I mention the C 2 fork because that is the one most frequently used in testing bone conduction. I have never seen a case of labyrinthine disease in which the intensity of bone conduction was increased. In testing ears with tuning forks we should bear in mind the necessity of having accurate forks and forks that are free from overtones. A fork with overtones will often give very different results from a fork free from overtones. Hold the fork by the handle and strike with a pencil on about the middle of the

prong, and if it gives a ring it has overtones and is not desirable; but if it gives a dead sound, you will then probably get a pure, clear tone and the fork is of value in making these tests.

Dr. G. McAuliffe, New York City—In dealing with cases of neurasthenia or allied conditions of nerve exhaustion, we should not hold the tuning fork too long in front of the ear. After resting the nerve if we will again approach the ear they will again appreciate the sound. If we do not do this we would get a shortened perception. Another point, in trying the Weber test—which I find the most unreliable one—is to place the fork underneath the mastoid, at the beginning of the sternomastoid. I have been able to get the proper response to the Weber test by this procedure.

Dr. S. Voorhees, Elmira, N. Y.—I would like to ask the Doctor if he does not find, for instance in labyrinthine disease, the higher tones are lost and the lower tones only recognized.

Dr. B. A. Randall, Philadelphia—I think it is extremely important to get forks that are somewhere near what they purport to be. On testing on the kymographion the various forks furnished you will get some very peculiar results. It is very seldom that they will give the rapidity of vibration set down for them. Second, the value of the fork should be expressed in the frequency of the vibration and not by a symbol, which is so varying in its employment that the term "C fork" may represent at least three different octaves. It is better to employ the complete double vibration instead of the half vibration, as is done by most continental workers. Third, the blow struck should have some semblance to standardization, and in the tuning forks we should have some idea of the bulk of metal vibrating. Not too much of the metal should be in the handle, which should be long in high tuning forks, lest the fork be really heard largely through the air when resting on the head. If we are stating that a fork of, say, 213 1/3 d.v.s., is heard after a standard blow for so many seconds, let us have a standard that it has fallen its own height, that it is of such a length and such a weight. Then when men having different sized forks get different results we will have some clew as to why their results appear different when they are really the same. These things are extremely important; they are really fundamental to any understanding of the matter.

Dr. William L. Ballenger, Chicago—In reply to Dr. Voorhees, as a general proposition there will be a loss of hearing for higher tones. The paper I left at home is a discussion of just such subjects as have been brought up in the discussion. It gives the technic of observation and testing and is intended as an answer to such objections. This paper only deals with the general principles.

THE TREATMENT OF TRAUMATIC GANGRENE OF THE EXTREMITIES.*

VAN BUREN KNOTT, M.D.
SIOUX CITY, IOWA.

In this brief paper it is my aim simply to call attention to a procedure which, in my experience, has proven of great utility in the management of these very troublesome and too often fatal cases. I shall not take up the pathology of traumatic gangrene, for with that you are all familiar, but shall confine myself to its treatment.

On referring to the literature we find all authorities agree that the only treatment of this class of cases consists in early amputation above the gangrenous area.

How often are we able to determine accurately the limits of the disease, particularly in those cases of rapidly spreading moist gangrene? Too often we are disappointed by the continuation of the process after amputation, and are compelled to reamputate much higher, in spite of which the patient often dies.

Again, if the gangrenous process does not involve the entire limb the flaps frequently slough, necessitating another operation and the sacrifice of what is too often most valuable tissue so far as the future usefulness of the part is concerned.

In other cases I have been convinced by subsequent events that in my effort to get well above the disease I have sacrificed tissue which might have been saved. In other words, I have amputated at a higher point than necessary. The occurrence of any of these conditions neither contributes to the welfare of the patient nor to the peace of mind of the surgeon, and we are all anxious to avoid them as completely as possible.

In casting about for the probable cause of the unsatisfactory course pursued by many of these cases I became convinced that it was the attempt to form flaps from tissue the vitality of which is always seriously in question and the further impairment of that vitality by two procedures necessary to this method of operation. First, the dissection of the flaps; second, the introduction of sutures.

The dissection of the soft parts into suitable flaps necessarily interferes with its blood supply, which interference in the class of cases under consideration is often illy born and frequently resented by sloughing of the flaps or the rapid extension of the gangrenous process up the limb. The introduction of sutures at this time has two distinct disadvantages. The first is the retention within the wound of infectious elements which may have traveled up between the muscle planes or along tendon sheaths to a higher point than we believe probable.

The second is the further interference with the flap nutrition by the suture tension which, no matter how carefully they may be placed, can not entirely be avoided. Believing the statements above made to be true, and that the bearing of these facts on the results secured in these cases was most important, I began about two years ago to treat all cases of traumatic gangrene of the extremities by a method which was entirely original and of which I have been able to find no mention in the medical literature at my disposal.

The procedure is as follows: Being confronted with a case of traumatic gangrene of an extremity, estimate as exactly as possible the line between the diseased and healthy soft parts, and having first under anesthesia made a most careful and complete disinfection and cleansing of the skin, puncturing all bullæ and removing all discharges, envelop the gangrenous area in a sterile towel up to the line selected and at this point make a circular amputation, cutting through soft tissues and bone at the same level. Ligate carefully all bleeding points, including none of the perivascular tissue in the bite of either the forceps or the ligature.

Leave the wound absolutely open, not introducing a single suture, and apply moist dressings of gauze saturated with salt solution. The dressings to be changed two to four times in twenty-four hours, as the circumstances of the particular case demand.

After seven to ten days, if the wound is perfectly clean and the condition of the patient favorable, the classical circular amputation may be made by dissecting up the flap already outlined and sawing the bone at the proper level. If for any reason the circular method may seem undesirable, any other procedure may be substituted, but in the class of cases under discussion a typical circular amputation will be found entirely satisfactory.

I will not burden you with a report of cases, but will simply state that I have employed this procedure four times, once in the upper third of the thigh, once in the middle third of the forearm and twice in the upper third of the leg with uniformly good results.

* Read before the Iowa Association of Railroad Surgeons, Oct. 16, 1902.

CONCLUSIONS.

As my results by the old method can not be compared with these I have ventured to bring the procedure forward for consideration. Its advantages seem to me to be many and its disadvantages few.

1. By it we may speedily and with the minimum of shock remove from an enfeebled and exhausted patient the source of the infection, namely, the gangrenous tissue.

2. We may frequently make the amputation at a lower point than would be possible by the old method, because soft tissues whose vascular connections are left undisturbed are less apt to slough.

3. The freest possible drainage is provided for a sufficiently long time.

4. If the disease stops at the line first chosen no unnecessary sacrifice of tissue has been made, as the flaps have been defined at the lowest limit of safety and the bone would necessarily have to be sawn at the same point as at the second operation.

5. If the limits of the disease have not been placed sufficiently high the same procedure may be repeated with less danger to the patient than a typical reamputation.

6. Patients too weak and prostrated by sepsis to withstand a typical amputation may endure this much shorter procedure and be built up during the interval before the second operation is necessary.

I hope that use will be made of this method in the future management of these cases that its value may be more fully and satisfactorily proven or disproven.

POISONED WOUNDS BY THE IMPLEMENTS OF WARFARE.*

LOUIS A. LA GARDE, M.D.
MAJOR AND SURGEON, U. S. ARMY.

Mr. President and Fellows of the College of Physicians: In the first place allow me to thank you for permitting me to address the honorable College of Physicians in the capacity of Mütter lecturer. In looking over the names of the distinguished men who have preceded me in this function, I admit that your invitation was accepted with a great deal of hesitancy. I accepted the charge because of a sense of duty to my department, and because it has been my good fortune to serve in most of the principal seats of learning in this country, and my observations have led me to the conclusion that there is a deep bond of fellowship between the military surgeon and his brethren in civil life that is largely cemented by a mutual love of all that is lofty and inspiring in the healing art. Your opportunities to set the pace as we advance in scientific medicine are superior, and your liberality in imparting great truths as we come to drink anew at the fountain of knowledge are well remembered. In return for the kind attention which you are wont to bestow on us when we resort among you, I beg of you to accept this effort as a mark of the gratitude which the military surgeon owes his civil confrère.

In discussing poisoned wounds by the implements of warfare it will appear difficult to separate them from infected wounds by these implements, and justly so. The terms are considered interchangeable in this instance so far as they relate to the transmission of micro-organisms, and it was considered expedient to retain the former term in order to conform to the old idea of poisoned wounds from poisoned arrows, lances, etc.

I. HISTORICAL.

The poisonous nature of wounds by the implements of warfare—especially those from firearms—has been dwelt on by the majority of the older writers. Frequent reference is made to the subject by John de Vigo, and Ambroise Paré was so imbued with the venomous nature of such wounds by reason of the powder, that he was wont to "cauterize them with oil of elders scalding hot, mixed with a little treacle." His trepidations in one instance when his boiling oil mixture ran out are graphically told by his biographer. In the absence of anything more efficacious he was driven to the use of yolk of eggs, oil of roses and turpentine in the treatment of the remainder of the wounded. After a sleepless night spent in anxiety for those who had not been given the conventional treatment of the day, by hot burning oil, he found, to his astonishment, that they had suffered but little pain, and their wounds were without inflammation and swelling, having rested fairly well the night before; the others, on whom the boiling oil was used, were feverish, with great pain and swelling about the edges of their wounds. Thus disinfection by heat as he practiced it gave results rather confusing and conflicting.

On the other hand, Thomas Gale, in his treatise of wounds by gunshot, attempts to refute the erroneous notion of Ambroise Paré, Jerome Brunswicke, John de Vigo, Alfonse Terrius and others concerning the venomous nature of gunshot wounds.

It is seen, therefore, that, from the beginning, the belief in the septicity or asepticity of gunshot wounds was indulged in. As to the value of the heat of ignition, if any, to purify the missiles as they issue from firearms, we will speak later.

Poisoned wounds from the use of so-called sidearms, or more properly speaking, cutting and stabbing implements, like the spear, sword, arrow-heads, knives, javelins, etc., have a very interesting literature, dating back to the days of the Greeks and Romans. A practice that is abhorred to-day and classed among the most cowardly deeds in the list of crimes, seems to have been pretty generally adopted in ancient times. For a complete account of the use of poisoned arrows, including an outline of the toxicology of the substances employed for the purpose by the ancient peoples of Europe, we are indebted to Gustav Lagneau. He points out that specimens of arrows gathered from the later paleolithic periods give proof that the art of poisoning arrows was known to the inhabitants of prehistoric times. Arrows made of bone to serve the points of javelins, lances, etc., are to be found in numerous archeological collections, and they suggest by the method of preparation that they were designed to carry poisons. Their surfaces show furrows and grooves, disposed parallel to the sides; grooves are also found on the teeth or serrated margins, for the reception of the poisonous matter, similar to what we find on the arrows of more modern periods.

The literature of historic times gives ample evidence of the use of poisoned arrows against man and beast. Thus Aristotle relates that the Celts in the hunt used poison on their arrows which was called *toxic.* After wounding a deer, for instance, it was considered necessary to excise the seat of injury at once, in order to insure the safety of the meat as food and to prevent rapid decomposition. The Gauls, according to Pliny, dipped their arrows for the hunt in hellebore, which had the

* The Mütter Lecture, delivered at the College of Physicians of Philadelphia, Dec. 2, 1902.

effect to make the meat more tender after excision of the wound area. These same people used an herb called *limeum,* which was known among them as deer poison.

Lagneau again cites numerous references to show that the Franes of the Rhine district and beyond used arrows dipped in the juices of numerous herbs that were so deadly that death was sure to ensue though the wound was trifling and in non-vital parts. The practice of using poisoned arrows in war became so frequent among the Franes that a law was inserted in their code in the fifth century to prohibit their use; the penalty on conviction being a fine of sixty-two and a half sous, or about sixty cents in our money. The same proscription was embodied in the Bavarian law later, although the penalty was not so great—the fine being a maximum of twelve sous. The Vandals, who originally inhabited North Germany, used poisons on their war implements, knives, lances, javelins. Pliny considered aconite the most deadly among the poisons so employed. The Europeans must have continued the practice of poisoning the implements of warfare to a late day, because M. Claude Bernard is said to have observed that Alonzo Martinez Espinoz, Porte-Arquebuse to Philippe III, admitted that a poison was manufactured by the Spaniards at that time from the root of the hellebore with which their implements were treated. Without extending the subject further it may be admitted from the copious references at hand that the peoples of Europe, generally speaking, engaged in the practice of poisoning the implements used in the hunt and in war. The practice is even known to have extended to the Scythians and the people of the far East.

The number and nature of the various poisons thus used on missiles and weapons like arrows, darts, javelins, swords, lances, battle-axes, etc., are commented on by Lagneau quite extensively. Of the vegetable poisons most commonly employed were extracts of hellebore, aconite, yew, limeum, ninum, helenium and that of a certain fig tree. The poisonous nature of the former of these is recognized to this day, since we extract from them the powerful alkaloids, like veratrin, aconitin and taxin; while the nature of the latter, namely, limeum, ninum, helenium and the fig tree mentioned are unknown to us now. Some of these poisons were said, like curare, to cause death when introduced through a wound, while they remained innocuous when ingested *per os.*

The poison materials were not confined to vegetable products alone. Ovid, who lived in exile about the Propontis, in the ninth century of our era, wrote on the custom of the nations of Eastern Europe, who, like the Scythians, poisoned their war missiles with venom of the viper, as well as the bile and blood of this reptile.

If we pursue the subject to more recent times we find that definite methods of poisoning missiles in warfare and for the hunt abide to this day with certain aboriginal peoples on the west coast of Africa, the South Seas, India, Indo-China, etc. Blood, decomposing viscera, snake venom and plant extracts are the substances usually employed. Siegfried in a general way tells us that "in Oceanica and the East Indies the plants employed are cardiac depressants; in the New Hebrides and some of the South Sea Islands the poison is like strychnin in its effects; in Africa various poisons are employed, including anthrax; and in the tropical waterways of the Amazon and Orinoco, curare and similar plant extracts." Ledantec, whose personal experiences had led him to suspect the poisonous nature of the arrows used by the latter, conducted some interesting experiments in the laboratory at Nouméa, New Caledonia and at Bordeaux, the results of which confirm in a measure the presence and nature of certain poisons. The arrows of the natives of the New Hebrides are propelled from a bow. They are about three feet in length, composed of a shaft made of light material like reed cane, a middle part composed of a hard wood, with a sharp point fixed on the end of the latter. The point is made of a piece of human bone, usually from a long round hard bone like the ulna or fibula, brought to a sharp, slender point to invite fracture and lodgment of part of the missile on penetrating the tissues. These osseous points are coated with a dark substance resembling wet powder grains when they have been allowed to dry in mass. These powder-like bodies constitute the poison. In the Nouméa laboratory he used guinea-pigs. Under strict antiseptic precautions he inoculated the poison from old arrows previously moistened with bouillon, under the skin of the back and abdomen. His results were only partially successful; that is, he obtained the clinical picture of tetanus in some cases, such as contraction or extension of the posterior extremity, contraction of the muscles of the dorsal region, opisthotonos, etc. His later experiments at Bordeaux with the poison from fresh arrows, prepared only six months before, were attended with more definite results. A guinea-pig inoculated with the poison from the recently prepared arrows died very promptly, within twenty-four hours. The postmortem evidence, microscopic examinations of cultures taken from the blood of the heart, and subsequent inoculations into animals confirmed the presence of malignant edema. From this partial examination of the poison he concludes that: first, the bacillus of Nicolaier resides indefinitely in the arrow poison, because the clinical picture of tetanus was so clearly shown in the animal inoculated with the poison from the old arrows; and second, that the poison of the recently prepared arrows contains malignant edema in addition to tetanus, a supposition that is reasonable enough from his inoculation experiments as well as from our knowledge of the ready susceptibility of malignant edema to moisture.

The source of the poison is of itself interesting. From a native of the New Hebrides who resided at Nouméa the following method of preparing the arrows was learned: With a stone an incision is made in the bark of a tree called Dot. A milky fluid escapes, with which the arrow points are coated. This fluid, of rather thick consistency, serves the purpose of fixing the poison proper. The point of the arrow is now wrapped with thread, leaving a space between each round. The arrow thus prepared is dipped into the mud of crab-holes; after drying the thread is unwound, when the weapon is ready for use. It is supposed that the thread is removed to give the point a rough surface and to increase the area from which poison is absorbed.

The French have had occasion to observe the subject of poisoned arrow wounds a great deal in their Chinese possessions. Boinet and Hedón describe the arrows used by the Muongs in Tonkin, China, as made of bambco 40 cm. in length, half a cm. in diameter and weighing six grams. Their points are coated with a brownish poison soluble in water; the solution resembles that of curare. On each arrow it is possible to recover 50 cg. of the poison. They experimented altogether on twenty animals, and sum up their work as follows: Three drops of a solution of 50 cg. of the poison to 10 grams of water deposited on the heart of a frog stops its beat

in seven minutes, and a centigram of the same solution subcutaneously administered is sufficient to kill a guinea-pig. Examination of the poison shows it to be made from the leaves of the *Antiaris toxicaria* or *Upas antiar*, the Javanese poison tree, a cardiac depressant.

The English have referred a great deal to the subject of poisoned arrows in their Indian service. Waddell, while professor of chemistry at Calcutta, examined the arrows prepared by the Akos, who occupy the Assam valley to the north of the Bramaputra. They use their poisoned arrows for large game and most effectively in warfare, as was shown on the Sepoys who operated against them some years ago. The physiologic effects of the poison on the arrows were those of aconite and the roots from which the poison was obtained belonged to a species of aconitum.

According to the researches of Gley and Lapique, strophanthus is one of the poisons used by some tribes in the center of Africa. An injection of one or two milligrams under the skin of a frog of the crude substance obtained from arrows and reduced to an aqueous extract, or two or three centigrams under the skin of a rabbit or dog, arrested the heart in systole in six to seven minutes. Analysis of the poison showed it to be *Strophanthus hispidus*.

Fraser and Tillie, who have studied the chemical properties and pharmaceutical action of the wood from which arrow poison is prepared by the Wa Nyika and other tribes of east equatorial Africa, confirm the presence of strophanthin as the poisonous agent on the arrows of these people. On frogs the prominent effects which follow the subcutaneous injection of large lethal doses are: slowing and intermittence of respiration, gaping of the mouth, often accompanied with straining movements like those of vomiting; fibrillary twitchings of muscles, especially at the seat of injection; impairment of motor power and of co-ordination; disappearance of cardiac impact; cessation of respiration and gradual enfeeblement and loss of reflex and voluntary movements.

In specimens of arrow poison furnished Tillie from the Rio Verde tribe of Indians in New Granada he was able to extract curare as the basis of the active poison. This, as already stated, is the favorite poison used by the tribes in the South American districts bordering on the Amazon and Orinoco.

Gärtner has recently called attention to a heart depressant used as an arrow poison by the Negritos of the Island of Luzon of the Philippine group. The poison is obtained from the bark of a tree called abuhab by the natives, the scientific name of which is *Raboloisia philippinensis*, the botanic description of which is minutely detailed by the author. He was able to obtain an extract from the bark of great potency, 0.1 gram inserted under the skin of a frog arrested the heart action in eight minutes.

The methods pursued by the North American Indians are more varied and for the most part not so deadly. Hoffman tells us that the Comanches employed the juice of the Spanish bayonet (*Yucca augustifolia*), which they obtained by piercing the skin of the plant with the arrow points. The ceremony of thus preparing the arrows is directed by the war chief after a period of fasting and self-torture by the young warriors. The Lipans are said to plunge the points of their arrows in the menstrual blood of a woman, while the Apaches prepare their poison by grinding the heads of rattlesnakes with fragments of deer liver. After decomposition has been allowed to take place the arrow-heads are dipped in the mass and subsequently set aside to dry. The Moqui Indians of Arizona prepare a poison that is said to cause death in the course of three days, which they call Ti-ki-le-li-oui. It is prepared as follows: A rattlesnake is irritated to the point of madness, when it inflicts stings in its own body, from which blood begins to flow. At this juncture of the religious ceremony the high priest of the order of snakes dips the arrow points in the sanguineous fluid. The less deadly methods of preparing arrows by the same tribe is that of dipping them in a mixture of the bodies of bees or red ants ground in a stone mortar. The wounded from a missile thus prepared are said to suffer from pain and swelling about the pharynx and in the part hit, and subsequently with fever and delirium. Invalidism is said to persist for about one month.

II. THE COMPOSITION AND MANUFACTURE OF AMMUNITION WITH REFERENCE TO THE PRESENCE OF INFECTION.

The practice of poisoning missiles after the introduction of firearms became less frequent. The superior deadliness of these weapons over those of the sidearm class rendered the employment of accessory methods, like the use of poisons to ensure death, unnecessary.

In view of the amount of heat which is generated with the ignition of explosives, the possibility of poisoning bullets for the purpose of conveying infection has often been debated. In considering the septicity or non-septicity of projectiles, it may be stated, that until the formulation of our bacteriologic technic, as now practiced, it was impossible to accurately determine the pro or con of this interesting question. Those who in former times advocated the asepticity of projectiles did so on the evidence afforded by their uniformly good results in the clinical field; whilst those who opposed the idea did so on the evidence furnished by unfavorable results from the same quarter.

As a preliminary to some observations on the bacteriology of ammunition, it is proper to carefully investigate the method of manufacture of the different articles entering into the composition of ammunition, such as the explosives and the wadding, as well as the shells, and also the technic of loading. In this way only can we determine whether the methods employed are calculated to purify or contaminate the missiles that are concerned in the production of gunshot wounds.

Black Powder.—We are informed by prominent makers of powder in this country, notably the E. I. Dupont de Nemours & Co. of Wilmington, Del., that the purity of powder is assured by the high degree of heat to which the three ingredients of the powder are subjected before being incorporated in the form of an explosive compound. These ingredients, as is well known, are: saltpeter 15 per cent., sulphur 10 per cent. and charcoal 75 per cent. In refining saltpeter the saturated solution of the crude material is heated to a temperature of 250° F.; the sulphur is fused from the crude brimstone, in order to remove extraneous matter; and the charcoal is obtained from willow wood after being subjected to a high temperature in a retort.

Smokeless Powder.—The so-called smokeless powders are for the most part secret compounds divided into two principal classes, viz., those made up of guncotton and the others having picric acid as a base. The former of these are used almost exclusively in the military rifle. The Schultze Gunpowder Co. informs us that their

"E.C." powder has for its base guncotton of various nitrations, which, as is generally known, consists of treating cotton with a mixture of strong sulphuric and nitric acids. The guncotton so obtained is next thoroughly purified by washing with boiling water, the temperature being never less than 212° F. As to the subsequent processes only the purest of salts, such as nitrate of barium and potash, are used to be incorporated with the guncotton. The grain is next gelatinized with solvents, like alcohol, ether and acetone.

It would be trespassing beyond the limits of this lecture to detail the mode of manufacture of the many smokeless powders found in the market, but it is sufficient to state that the extra care undertaken to exclude impurities is calculated to render the powders sterile, as they issue from the factory at least.

Wads.—According to the Union Metallic Co., cardboard wads are manufactured from newspapers soaked in hot water, and when reduced to a pulp the material is run through a refining engine. It is then treated by machinery to convert it into a web of desired thickness. When taken from the machine the sheets are dried and finished with a hot roller. Wad-felt, another material used for wads, is, according to other manufacturers, made from wool, hair, soap, flour, glue and china clay. White paper is pasted on both sides of the felt. This wadding material is next subjected to hydraulic pressure, then dried and cut in strips, after which the strips are run through a cutting machine. The final step in the process consists in lubricating the edges of the wads with stearin heated at 130° F. As far as can be learned there is nothing in the process of manufacture to insure wadding material from contamination.

The Manufacture of Metallic Shells and the Process of Loading.—Ordnance Memoranda, No. 8, of the U. S. Army, describes the following method of manufacture of the center-fire metallic cartridge, which is about the same as that employed by private firms. Although there have been some improvements in the process of manufacture since the circular was issued, the employment of heat and the use of acids and alkalies remain about the same.

The cartridge consists of the following parts: (1) The case of copper or brass, (2) the cup anvil, (3) half a grain of percussion composition, (4) 70 grains of musket powder, (5) a lubricated bullet weighing 500 grains.

During the manufacture of the copper cases they are annealed once or twice by subjecting them to a red heat in a charcoal fire. They are subsequently treated once with a solution of sulphuric acid in water (1 to 15), and twice finally with a solution of caustic potash and caustic soda, one and a half pounds of each to five gallons of water, after which they are thoroughly dried in a drying room at a temperature of 125° F.

The lead of which the bullets are made is melted and skimmed of dross, after which it is cast in cylindrical molds of suitable diameter and length. The subsequent steps of compressing the lead and cutting the bullets into proper length is done entirely by machinery.

The act of loading is also accomplished by machinery, and before each bullet is pressed into its copper case its surface and cannelures are lubricated by a mixture of grease and wax which has been previously subjected to a high temperature.

The Union Metallic Cartridge Co. describe the method of loading metallic and paper shells as follows:

The shells, after being primed with fulminate of mercury, are placed in plates holding them securely and filled with powder; over these plates of charged shells another set of plates holding bullets or wads, as the case may be, is placed in perfect alignment with the shells beneath. By means of a pin-plate wads or bullets are forced in place, after which the shells are crimped. The paper shells are placed on a rotating dial, which deposits them singly in a receiving chamber, where by an intermittent action of the machine they are loaded with powder, wads and shot.

The cartridges are finally packed and hermetically sealed into paper boxes, the frames and skeleton divisions of which are made of tarred boards. The employment of heat, acids, alkalies and absolute cleanliness are said to be necessary by the manufacturers of ammunition to insure the keeping qualities of the powder and to obtain constant results in firing, precautions which doubtless add to the sterile properties of the cartridges.

Having in this way investigated the origin and preparation of ammunition, it was next considered proper to study its bacteriology.

III. THE RESULT OF BACTERIOLOGIC INVESTIGATION AS FAR AS IT RELATES TO BULLETS, GUNPOWDERS AND WADS, BEFORE AND AFTER FIRING.

1. *Bullets.*—In a bacteriologic study of bullets from original packages we found that the cleanly methods employed in the manufacture of ammunition tend to sterilize the projectile in a majority of cases. A score of bullets were extracted from brass shells by means of sterile forceps and dropped in as many tubes of gelatin. After the lapse of a few days 53 per cent. of the tubes failed to show any growth, and those containing colonies were found free from septic germs.

In order to ascertain the effect of firing on the bacteria that might be found lodged on a contaminated bullet, a six-chambered 38 caliber Colt's revolver was sterilized for one hour in an Arnold's sterilizer before firing. At a range of 13 feet 12 cartridges that were lying on the floor of an unswept room were fired from the sterile pistol into an iron target enveloped in a wire screen, the target and the screen having been previously sterilized by the flame. As each shot was fired the target was sterilized anew. The projectiles and fragments of the same were collected as rapidly as they were fired, from the sterile screen, and dropped in agar-agar tubes at 42° C., and converted into Esmarch rolls. At the end of 48 hours, at the ordinary room temperature, all the tubes showed growth and the majority of them contained scores of colonies.

2. *Black Gunpowder.*—(*a*) The components of black gunpowder (sulphur, saltpeter and charcoal) obtained from the Dupont Powder Works, Wilmington, Del., were separately examined by placing a few grains of each in a half dozen bouillon tubes. Under favorable conditions of temperature growth only occurred in those containing charcoal. This was undoubtedly the result of contamination in handling, as the charcoal was obtained loose, wrapped in a piece of newspaper. Otherwise, as already intimated, charcoal is sterile from the high degree of heat to which the willow wood is subjected in the retort. The antiseptic property of the other components accounts for the negative results with them, no doubt. The saltpeter was the subject of special study, because the crude material is obtained from saltpeter beds in the earth where every opportunity might exist for the introduction of tetanus and other impurities. Still, as already noted, the refining process employs such an amount of heat, 250° F., as must preclude the persistence of the most resistant spore-forming bacteria, so that the heat and antiseptic value of the chemical product together most likely account for the absence of growth in the bouillon tubes belonging to this series.

(*b*) We next examined the powder charge of blank cartridges from three different makers, viz.: the Domin-

ion Cartridge Company, the Eagle Metallic Cartridge Company and the Union Metallic Cartridge Company. Every precaution was observed to prevent contamination during the operation of unloading the shells. The latter were immersed in a 1/1000 solution of mercury bichlorid for sixty minutes before the wadding, which was non-absorbent, was removed with a sterile pin. The full charge of powder was added to a tube of bouillon, and altogether 41 tubes were thus prepared from the different ammunitions. Placed in the incubator at 37° C. aërobically and anaërobically at the end of 24 hours 12 per cent. of the tubes showed growth. The contaminated tubes might have been the result of accident in the technic, but more probably some of the cartridges were normally contaminated in the process of loading. Although powders are generally found pure for the most part, yet some samples are often very trashy, as those used in the manufacture of firecrackers. Tests made with the latter show that contamination is present in 76.6 per cent.

(*c*) To determine the value of powder as a disinfectant, we dropped 12 grains of sterile powder in each of twelve tubes, and having found no growth at the end of 24 hours under favorable conditions of temperature, we inoculated each tube with a culture of colon bacillus. The growth of the latter was not interrupted, showing that black gunpowder *per se* does not destroy or restrain the growth of this organism.

(*d*) The next step in our experiments had reference to the potency of the heat generated in the chamber of a gun to sterilize the unburned grains of powder at the moment of ignition. It is of interest to know in this connection that in firing an ordinary hand rifle only 43 per cent. of the amount of powder is consumed in the generation of the gases. The remaining 57 per cent. of the charge is propelled at distances varying with the amount of the charge, the standard of the powder and the caliber and length of the barrel. The grains of powder that are imbedded in the tissues to produce what we generally designate as powder-burn are not consumed in the act of firing. This is well shown by firing into blotting paper and collecting the grains that are caught in the latter. When placed in a saucer they are easily ignited by a burning taper. It was natural at this point that we should inquire into the fate of organisms that might be accidentally or otherwise placed on the unburned grains of powder that go to make tattoo marks or "powder-burn." We purposely contaminated the powder charge of 24 Springfield carbine cartridges and fired these into 24 targets of agar-agar and gelatin plates at five feet. Each target contained four of the plates secured in place by wires. Out of eighty plates thus prepared—the others having been destroyed by the ball or the force of concussion—growth was present in every instance at the end of 48 hours. In order to determine the likelihood of contamination by the disturbance of the intervening air, twelve shots were fired with sterile powder into twelve targets of four gelatin plates each. Growth only appeared in 5 per cent. of the 48 plates when placed in the incubator, showing that the opportunity for contamination by currents of air that are forced against the target by the propulsion of the charge is very small.

3. *Smokeless Powders.*—The bacteriology of smokeless powders was next considered. The experiments about to be described were conducted with the "Peyton powder"—a compound of nitro-cellulose—now used by the U. S. Army in the military rifle. Although we have every reason to believe that this powder is contaminated by handling in the same way that the old black powder is, we fail to obtain growth when we place a few grains of it in media like bouillon, gelatin or agar-agar, etc. This powder imparts a yellowish color to the media. After repeated trials I have failed in cultivating *B. prodigiosus* in bouillon to which a few grains of the powder had been added. It would seem from this that the Peyton powder contains a substance which inhibits the growth of certain bacteria in the media mentioned. On the other hand, if a bouillon tube containing a few grains of Peyton powder is inoculated with anthrax spores, growth will be noticed at the end of 24 hours under favorable conditions of temperature, showing that the restraining influence of the powder does not apply to the more resistant forms of germ life.

If the experiment of firing black powder into agar-agar or gelatin plates be repeated with the Peyton powder, whether this be sterilized or not, the powder grains which are caught on the media impart no growth as a rule. The yellowish discoloration already mentioned is invariably noticed around each grain. If, however, we purposely mix earth in the proportion of 10 to 20 per cent. with the powder before firing, colonies will appear in great numbers in the media beyond the area of discoloration, and sparingly, if at all, within the latter.

Out of six gelatin plates fired into at ten feet with the Peyton powder, which was previously contaminated with dust, colonies were observed in two of the plates. More recently on working with the Dupont brand of smokeless powder we have observed growth in a small percentage of the samples examined. Nimier and Vincent, in their experiments with the explosive used by the French, and Deubler, while experimenting with the smokeless powder of the Austrians, established that their smokeless powders were contaminated, although they failed to isolate pathogenic cocci.

4. *The Wads.*—The wads were examined as follows: Twelve pasteboard wads from as many .22 caliber cartridges used in the toy pistol manufactured by the Dominion Cartridge Company, were removed with an aseptic pin from their shells and dropped into separate tubes of bouillon. Growth was present in every tube, both aërobically and anaërobically in the Novy jar. These tubes were then examined for tetanus and malignant edema, by animal inoculations, with negative results.

Similar examinations were made of wads composed of felt and cardboard from other firms, with evidence of contamination in every case. The results are not surprising, in view of the source of the material entering into the composition of the wad as well as the absence of anything in the technic of manufacture which is calculated to destroy infection.

The influence of the heat of ignition was tested by firing wads into plates of gelatin and agar-agar. Sterile wads were contaminated with dust within and without, on the surface next to the powder and that facing the target, and in every instance the result proved that the wad remained contaminated.

Having shown that the act of firing failed to destroy micro-organisms that were casually placed in the ammunition, we next proceeded to experiment with distinct bacteria.

IV. THE TRANSMISSION OF DISTINCT BACTERIA BY VARIOUS MEANS IN FIRING: B. ANTHRACIS, B. RUBER, B. COLI, STREPTOCOCCUS PYOGENES AND B. SUBTILIS.

In 1892-5 we were able to show the effect of firing bullets and powders that had been previously contam-

inated with distinct bacteria. For this purpose we infected bullets and powders with anthrax and fired them from different weapons with the following results:

Bullets.—Before we undertake a recital of these experiments it may be well to recall the fact that we have already demonstrated that unclean bullets, such as those taken from the floor of an unswept room, the ammunition belts of soldiers, etc., when fired in sterile cotton, are not purified by the act of firing. To make this more apparent we conducted additional experiments as follows: From a sterile .38 caliber Colt's revolver, at ranges varying between five and ten feet, we fired 17 shots into baskets of sterilized jute or cotton. Each ball was previously infected with anthrax spores in a small hole drilled into the point of the missile and the hole sealed with yellow wax. After each shot the bullet was taken from the sterile cotton and the wax removed. The ball was dropped in a tube of bouillon, agar-agar or gelatin, and, in the case of the latter, it was converted into Esmarch rolls. Of the 17 tubes thus prepared, the *Bacillus anthracis* was recovered from 16, the failure being an instance where the ball was split into two parts by striking the basket. The focus of infection was very likely destroyed. We next infected the surface of the conical ends of five bullets of the same revolver with anthrax spores mixed with grease and wax 1-4. They were fired into a sterile iron target properly screened at a range of thirteen feet. The bullets made a regular impact in every instance, striking point on. They were recovered, as a rule, in a number of fragments with sterile forceps and dropped into tubes of nutrient media. Two days later every tube bore colonies of *Bacillus anthracis*. In order to better test the efficacy of the heat generated by the ignition of the powder, we infected four of the bullets with a culture of anthrax spores in the concave base next to the powder. They were fired into the same target and collected under the precautions already mentioned. Each bullet, or the pieces thereof, was dropped in bouillon. Every tube showed growth of the *Bacillus anthracis* at the end of three days. In order to determine this point with regard to the vegetative form of the organism, we infected 11 bullets in their concavity next to the powder with the blood of a mouse that had died of anthrax the night before. The projectiles were fired into the same target at the same range from the sterile revolver. They were dropped in as many tubes of bouillon with positive results in nine of the tests.

The outcome of these four sets of experiments shows that 92 per cent. of the projectiles remained infected after firing.

So far the experiments have reference to low velocity projectiles, impressed by 16 grains of black powder. The amount of heat imparted to the bullet is necessarily very small compared to that which is imparted, for instance, to a .45 caliber projectile of the Springfield rifle, or to the high velocity jacketed projectiles of reduced caliber like those of the Krag-Jorgensen, Mauser, Mannlicher or Lebel type.

The fate of anthrax spores on the Springfield rifle bullet was tested as follows: The bullets, weighing 500 grains, impressed by 70 grains of black powder, were fired into a target of pine boards, one inch thick, disposed at intervals of an inch. Three of the bullets were infected in depressions made by the pressure of a knife blade on the conical end of the lead. The firing was done at a distance of ten feet. The bullets penetrated 17, 18 and 19 boards respectively. As soon as recovered with a pair of sterile forceps, each bullet was dropped in a tube of bouillon. The bullets were very much set up, the grooves already mentioned were entirely effaced, and the tubes were all negative after the lapse of three days, which could only be attributed to the severe friction and mechanical effect to which the projectiles were subjected in traversing the wood fiber.

Three other bullets were infected with anthrax spores, in this instance in the concavity of the base next to the powder, and fired into a target of boards at a distance of ten feet as before. The penetration was 19, 23, and 18 boards in the order of shots fired. The bullets were recovered with sterile forceps and dropped in bouillon as before. The results were positive in two of the tubes at the end of 48 hours.

Along this line of work Dr. Pustoschkin has more recently demonstrated the effects of firing sterile bullets through infected clothing before and after the barrel had become heated from a succession of shots, as well as the effect after contaminating the ball or the barrel of the gun. She experimented with the Swiss military rifle of 7.5 mm., propelling a steel-clad bullet possessed with an initial velocity of 600 meters. (1) The firing was done at 7 meters through pieces of cloth that had been saturated with cultures of 1, *Bacillus ruber;* 2, *Bacillus coli;* 3, *Streptococcus pyogenes;* 4, *Bacillus subtilis.* In every instance the results were positive; that is to say, a sterile ball from a sterile barrel became infected with each of the micro-organisms mentioned when it traversed the infected cloth as shown by cultures of gelatin subsequently pierced by the ball. The experiments prove that a bullet even though possessed with high velocity can become infected in transit; and that the heat imparted to the ball from a heated barrel in addition to what may be acquired by the ignition of the powder is not sufficient to prevent said infection. (2) In this series she infected the body of the bullet with the same organisms. The results in gelatin were again positive, showing that the heat from the friction in the barrel in addition to that derived from the explosion of the powder is not sufficient to destroy micro-organisms placed on the body of the ball. (3) She next infected the conical ends of the bullets with organisms already mentioned. The gelatin was infected with one after the other of these organisms, but it was noticed that the number of colonies was far greater when the point of the ball was infected as compared to the preceding series in which the organism was placed on the body of the bullet. This is properly attributed to partial destruction of the germs by friction, whilst others remained adherent to the inside of the barrel. (4) The last of the series of experiments by Dr. Pustoschkin had reference to the fate of the organism when placed in the barrel of the gun. Sterile balls were fired through the infected barrel with positive results.

Black Powder.—The subject of the transmission of distinct bacteria by powder was undertaken by us at Fort Logan, Colorado, in 1895. We used an old culture of anthrax from an agar slant as follows: The spores were mixed with 55 grains of powder from the shell of the 45 caliber Springfield carbine. The charge of the powder was emptied on a sterile sheet of white paper, and a platinum needle, sterilized by the flame, was passed once into the culture of anthrax spores, and then a number of times into and through the powder until the grains of the latter no longer adhered to the needle. The needle having been again sterilized, it was once more passed through the culture, thence through the

powder as before. This was repeated four or five times for each charge of powder, six in all. The powder, thus infected, and the ball, which had in the meantime been sterilized in the flame, were replaced in the shell. Two Petri dishes containing agar-agar were placed in wire frames and the latter were suspended against a wooden target, four inches apart. The marksman was directed to place the ball as nearly as possible in each target midway between the two plates. In this way a number of powder grains were collected on each of the twelve plates, in four of which the *Bacillus anthracis* developed colonies.

Smokeless Powder.—The experiments herewith were conducted with the Peyton powder, already referred to. The powder was contaminated with anthrax spores as before. Out of six gelatin plates fired into at ten feet colonies of the *Bacillus anthracis* were observed in two of the plates.

(To be continued.)

Clinical Reports.

UNCINARIASIS—REPORT OF A CASE.

GEORGE H. EVANS, M.D.
Visiting Physician to St. Luke's Hospital.
SAN FRANCISCO.

Medical literature during the past year has been prolific with reports of uncinariasis in the United States, and a consideration of these cases would seem to infer that the nematode causing this malady is indigenous to this country. The uncinaria are found in several of the lower animals, as dogs, sheep and cattle in different parts of this country, and the investigations of Stiles[1] of the cases submitted to him for examination have caused him to base a new species on them, which he has named the *Uncinaria americana*, the new-world hookworm, in contradistinction to the *Uncinaria duodenalis*, or old-world worm. The chief mark of distinction lies in the fact that the new species presents the buccal capsule with a dorsal pair of prominent semilunar plates or lips and a ventral pair of slightly developed lips of the same nature, instead of two pair of ventral teeth curved like hooks, and the pair of dorsal teeth, as seen in the old-world form.

It is not intended in this report to enter into the natural history of the hookworm. The reader is referred to the recent articles of Stiles,[1] Clayton,[2] Capps[3] and others who have exhaustively reviewed the subject.

The following case is interesting, bringing up, as it does, the question of the geographical distribution of the *Uncinaria americana:*

NARRATION OF CASE.

David B., age 35, a native of Canada, was admitted to my service at St. Luke's Hospital, June 11, 1902.

Family History.—Father alive and well, mother died of some bowel trouble.

Previous History.—He had had diphtheria, luxation of left shoulder, white swelling of the knee. Previous to going to the Philippines he had spent his life in Canada, Alaska and the Puget Sound region. He was captured by the Filipinos and held captive for fifteen months, during which time he suffered great privation and physical hardship. After regaining his liberty he began to have diarrhea, with painful passages, and his tongue became sore and took on the raw, beefy appearance characteristic of sprue. He became progressively weaker and emaciated. His treatment during this time consisted of internal medication, enemas and light diet, later opium suppositories and morphin for the pain. His stools were irritating to the anus and of very offensive odor, numbering, occasionally, as many as thirty a day. There was no vomiting, but the slightest indiscretion in diet would cause considerable gastric distress and belching of gas. He gradually got worse and, after several months of this treatment, went to the Philippine Civil Hospital, where his stools were examined for the first time, and *Amœbæ dysenteriæ* were found. He was then treated with quinin enemas. Subsequent examination of the stools were negative, but he became worse and finally was put on the transport for San Francisco, arriving here May 23, 1902.

Examination.—Patient was thin, poorly nourished, skin sallow and of cachectic appearance. His tongue was of a raw, beefy appearance, with superficial ulcerations on the margins, and very sore. Buccal surfaces were also eroded and sore. Examination of the heart showed normal area of cardiac dulness; hemic murmur at pulmonary cartilage. Lungs negative. Examination of abdomen negative, with the exception of tenderness on deep pressure over small intestines and colon. Temperature at entrance 96.8, pulse 80. He was having several stools a day, which were light yellow, with considerable mucus. He was given the regulation doses of calomel and put to bed on an exclusive milk diet. As a result of this diet stools became lighter in appearance and less frequent. Several stools were examined for *Amœbæ coli*, with a negative result. Culture plates were made at different times, revealing only colonies of the colon family, no *Bacillus dysenteriæ*; patient's blood did not give agglutination test with a culture of Shiga's bacillus. Subsequent examinations were also made for Shiga's bacillus, but without result. A blood count at this time revealed 3,360,000 red cells; hemoglobin 70 per cent.; differential leucocyte count not made.

Treatment.—July 3, after continued search of the stools, ova of uncinaria were found by the pathologist of the hospital, Dr. Mary Halton. The blood count showed at this time 2,290,000 red cells, 3,150 white cells and 55 per cent. hemoglobin. Differential count: polynuclears, 40 per cent.; large mononuclears, 17 per cent.; small mononuclears, 19.5 per cent.; eosinophiles, 23.5 per cent. The next morning he was given one gram of thymol in capsule, followed at 1 p. m. by a similar dose, later in the afternoon giving him one ounce of castor oil. This was followed by several liquid passages, which were all examined, revealing ova of the uncinaria and one worm. About this time his tongue, which had improved very much on the milk diet to which he was subjected, became decidedly worse and caused him a great deal of pain.

July 12, ova persisting in his stools, he was given four doses of thymol during the day, consisting of one gram each. Following this another hookworm was found in one of the stools.

July 21 there were 2,500,000 red cells, 5,300 leucocytes, 50 per cent. hemoglobin. Differential count: polynuclears, 33 per cent.; large mononuclears, 8 per cent.; small mononuclears, 24 per cent.; eosinophiles, 35 per cent.

July 25, as the ova were still present, larger doses of thymol were given. After a preparatory cleansing of the bowels, four doses of two grams each were given in capsule at intervals of three hours. Examination of the stools following this last administration was negative. There was considerable reaction as the result of this rather vigorous treatment, and he was temporarily put on small doses of strychnin. His condition from July 28 steadily improved. His tongue also became less sore and lost the raw, beefy ulcerated appearance.

August 1 there were 2,450,000 red cells, 5,520 leucocytes, 60 per cent. hemoglobin. Differential count: polynuclears, 43 per cent.; large mononuclears, 5 per cent.; small mononuclears, 21 per cent.; eosinophiles, 31 per cent.

August 6 hemoglobin had increased to 60 per cent. and the cosinophiles had decreased to 24.5 per cent.

August 15 there were 2,660,000 red cells, 7,800 white cells, 65 per cent. hemoglobin, eosinophiles being up to 38 per cent.

September 7 the red cells numbered 3,200,000, leucocytes 5,200, hemoglobin 65 per cent., polynuclears 48 per cent., small mononuclears 24 per cent., large mononuclears 6.4 per cent., eosinophiles 21.6 per cent.

He left the hospital on September 20, promising to return regularly for blood counts. On October 24 blood count revealed 3,300,000 red cells, 7,000 leucocytes, 70 per cent. hemoglobin. Differential count: polynuclears, 58 per cent.; large mononuclears, 5 per cent.; small mononuclears, 17 per cent.; eosino-

philes, 20 per cent. He has failed to report for examination since that date. After the third administration of thymol, though the stools were examined for several days, no further evidence of the presence of uncinaria or its ova was observed.

COMMENTS ON THE CASE.

Though the increase in the number of red cells and the amount of hemoglobin, and the decrease in the eosinophiles were very slow, and, in fact, were far from normal at the time he left the hospital, still the man's rapid improvement from the time of the third administration of thymol and his steady increase in weight, increasing as it did from 105 to 140 pounds when he left the hospital, can scarcely leave any doubt that he has entirely recovered from his malady. This man has disappeared, but careful inquiry of his relatives and friends has elicited the fact that he has, in all probability, never been in other localities than those mentioned in the report.

The uncinaria found in his stools were submitted to Dr. Stiles for classification, who determined them as belonging to the species *Uncinaria americana* (number 9412, parasite collection of the United States Public Health and Marine-Hospital Service). From the fact that the patient was well until after a sojourn of fifteen months in the Philippines, it is hardly probable that he contracted his disease in this country. The inference would seem fairly clear that the *Uncinaria americana* is indigenous to the Philippines. Dr. Capps' case contracted his disease in Panama, and was an infection with the *Uncinaria duodenalis*, or old-world species. Thus we have both species found on the American continent, and, admitting that my case originated in the Philippines, certainly both forms are found there. It is important that these cases should all be properly classified, and it is very important that they should all be diagnosed. That a very large number of cases of extreme anemia with intestinal symptoms are due to this nematode is unquestionably true, and too much stress can not be laid on the necessity of examining the stools in all such cases. Such examinations, carefully made, will not fail to find the ova, if this disease be present.

The symptoms of sprue in this case make it more interesting. There is a dearth of literature on this subject. Manson describes the condition in his "Manual of Tropical Medicine," and it was the topic of discussion in the Section on Tropical Diseases at the annual meeting of the British Medical Association in 1899, where Thin considered the disease as of a specific nature.

Has sprue or psilosis a distinct entity as a disease, or does it exist merely as a group of symptoms in intestinal affections? This question has recently been raised by Musgrave,[4] who autopsied sixteen cases, in thirteen of which it existed as a symptom group in other diseases, and in two of which the uncinaria were found in the intestines, postmortem. His investigations, however, lead him to conclude that "it is more rational to consider sprue as a state or symptom-group occurring in the tropics in chronic diseases, especially those affecting the gastrointestinal canal." Manson[5] also considers it, not as one disease, but a variety of diseases with a series of symptoms in common. That my patient's sprue symptoms disappeared with the disappearance of the uncinaria is unquestionable, whether the disappearance is permanent, however, can not at present be known. An exclusive milk diet will often clear up these symptoms, only to return when mixed diet is resumed. Further researches will be necessary in order to establish the status of this interesting symptom-group.

Blindness in France.—In a report to the Ophthalmological Society, Dr. Trousseau states that the number of blind in France reaches 31,966; a proportion of 8 in 10,000. This proposition is considerably in excess of that in Denmark, Switzerland, Austria and, above all, Holland, where it is exactly 4.46 in 10,000.—"Medical News."

A CASE OF MYCOSIS TONSILLARIS AFFECTING BOTH TONSILS.

COMPLETELY CURED BY REMOVAL OF THE TONSILS BY ELECTRO-CAUTERY DISSECTION.

RICHMOND McKINNEY, M.D.
Laryngologist to East End Dispensary and to Presbyterian Hospital.
MEMPHIS, TENN.

Miss A. B., aged 23, concert pianist, came to me, Sept. 26, 1902, with a history of having suffered more or less with her throat for the last ten years, the first attack of "sore throat" having begun in Boston while en tour; recurrences having been frequent since. February, 1902, she noticed a whitish formation on both tonsils. This could not be removed by the ordinary means resorted to, such as gargles, sprays, etc. She consulted several specialists in different portions of the country, but none vouchsafed an opinion as to the nature of the disease, nor advised anything in the way of radical treatment.

Examination revealed in the sulcus forward of the posterior pillar of the right tonsil a fan-shaped, whitish growth, apparently fungoid in character. This growth extended from about midway of the tonsil up to the supratonsillar fossa. The tonsil was not hypertrophied to any considerable degree. The left tonsil presented practically the same condition, the growth occupying an identical relation to the organ, but was not so extensive, being perhaps only half the size of the other.

A portion of the growth was removed from the right tonsil for microscopic examination, my opinion being that it was a case of mycosis. The patient was also told that the best treatment would be to remove the tonsil by electro-cautery dissection, thus eradicating completely the source of origin of the growth. Since she was desirous of immediate relief, and had but a short while to remain in town, she consented to immediate operation. After cocainizing the right tonsil thoroughly with a 10 per cent. solution of cocain, followed by an application of adrenalin chlorid, 1/2000, the right tonsil was dissected away with a cautery point in one sitting. I barely had time to complete the operation before the patient, who was of a highly nervous temperament, had a hysterical attack of exceeding severity, accompanied by weeping, numbness of the extremities and tonic spasms of the fingers of both hands. Three weeks later she returned for removal of the other tonsil, and this was done with great rapidity in order to avoid, if possible, another hysterical attack. This was barely escaped, as hysterical symptoms began to manifest themselves toward completion of the operation.

A careful microscopic examination made in the interval between the operations showed an abundance of filaments of *Leptothrix buccalis* and mycelial threads, in various teased specimens that were prepared from the portion of the growth removed from the right tonsil.

This patient was seen twice after the last operation, the most recent examination of her throat having been made early in the present year (1903), and there was no indication whatsoever of a return of the growth of either tonsil.

Mycosis of the tonsils is not a specially uncommon disease, but it is infrequent enough to justify the reporting of such cases as are encountered in which there is no question of the diagnosis. This case, moreover, is unique in at least two respects. First, in that the growth did not consist of discrete rods or tufts, which usually is the case, but of conglomerate patches of fungus. Second, its complete cure by electro-cautery dissection, which must be accounted for by the thoroughness of removal of the organs from which the growth sprang, since it is the experience of every writer on this subject and of all observers of cases that the treatment of mycosis tonsillaris is very unsatisfactory, Grayson stating in his recent textbook on the diseases of the nose, throat and ear, that "Even with the greatest care, the cure of a well-developed case in less than six weeks or two months will be a credit to the practitioner."

THE DANGERS IN COMPETITIVE COLLEGE ATHLETICS.

Recent statements by prominent educators opposing modern tendencies in college athletics have been accompanied, it happens, by numerous publications with a similar tendency based on considerations of the purely physical dangers. As baseball has been displaced from its pinnacle of student adoration by the more violent football, and as the annual growth in the fierceness of competition is leading to more and more protracted training of the athletes in all competitive lines, whatever serious results may follow are likely to be greatly increased. From the standpoint of the educator the great question lies in the moral effect on the student body as a whole, and on the individuals participating, of the intensity of emotion and of interest that the great intercollegiate contests engender. For a large part of the year the interest of the athlete is centered on athletics at the expense of the many other things that go to make up the college career and training; for a number of weeks the same condition affects the entire mass of students. That both good and bad results may come is evident, and the effort of those in authority will probably be directed to so altering conditions that the good may increase as the bad diminishes, rather than to entirely cut out all intercollegiate contests, as some have urged. Intercollegiate athletic contests have too strong a hold on the public to be exterminated by faculty authority. But in addition to the pedagogic features of the question there are matters of pathologic interest and physiologic development that concern both the student of physical culture and the medical adviser. To the former the burning question is the tendency to center all effort on the team, or nine, or crew, that is to represent the institution in competition, and to which all eyes are turned through profusely illustrated newspaper reports as well as by appearances in public. The result is that a minute fraction of the university population, generally the part that already has through natural endowment or previous training the best physical development, is singled out for all the care, advice and training, while the average student who needs the attention far more is left more or less to his own devices. What should be the great aim of the school, to bring all to a proper degree of general development, is sacrificed to carry a very few to the utmost limits of power in some special line.

The results of excessive development of the few are of more immediate interest to the physician. During the process of training a few conditions are prominent: one is the hypertrophy of the heart, often with periods of dilatation; another is a greatly increased metabolism, attested to by the great fluctuation of weight which often amounts to several pounds during a single contest, and the enormous meals consumed at the training table. A study of the competitors in the annual "Marathon runs," held at Boston during the last few years, has just been reported. It is of much interest.[1] The men were examined just before and just after a run of twenty-four miles. While in some the pulse rate was not much increased, it usually was high, even 180 being recorded. In practically all cases the hearts, already hypertrophied from training, became more or less dilated, often with systolic murmurs. The temperature was invariably raised, and a leucocytosis corresponding in intensity and type with that observed in inflammatory diseases, generally over 20,000, was constant. The urinary examination indicated an active renal hyperemia, albumin, casts and blood being found at first, but these abnormal substances all disappeared in a week. An interesting finding was the decrease of urea for the first twenty-four hours following the race.

All of these changes indicate that in violent athletic exercise there is produced a great mechanical strain on the heart, and the presence in excessive amounts of the "toxins of fatigue" that cause much the same results as acute infection, namely, leucocytosis, fever, and renal injury. That repeated exercise, such as prolonged training in successive years, may lead to permanent injury of the heart or kidney is unquestionable—how frequently such is the case is altogether a different question, needing statistics of athletes after their period of active training, which statistics are obviously difficult of accumulation. The pathogenesis of interstitial myocarditis is too obscure to permit of dogmatic statements, but we know that when a tissue suffers atrophy of its parenchyma cells the interstitial tissue usually takes their place, and this fibrous tissue in contracting lessens the blood supply so that further atrophy follows, and thus a vicious circle is established. When an athlete subsides into a quiet life his hypertrophied heart muscle may readily undergo such change, and there is abundant evidence that it does. Constant hammering of a hypertrophied heart on the arteries can not well help shortening the existence of the "vital rubber" in their coats. G. Frank Lydston,[2] writing under the title of "Briefs on Physical Training," calls attention forcefully to the grave results that have been observed to follow in later years the athletic excesses of youth, not only in damaged cardio-vascular systems, but also in disturbed metabolism as manifested in "lithemia," whatever that may be. "The man who gets a great deal out of himself physically before the age of 30 is bound to 'go back' after

1. Observations on Long Distance Runners, edited by J. B. Blake and R. C. Larrabee, Boston Med. and Surg. Jour., 1903, exlviii, 195.

2. American Medicine, Feb. 21, 1903, et seq.

that period. The man who attains supremacy on borrowed energy—energy borrowed from his physiologic bank—is called on to pay his note sooner or later. He can not do so and goes into physiologic bankruptcy."

If in our fondness for the excitement of athletic contests we are leading to injury of the vital powers of young men, if we are encouraging a system that decreases their prospects of longevity, we may seriously stop to consider if the game is worth the candle. If we must have the excitement we can turn to other fields—the shortening of the life of a race horse, or of a game cock, or even of a professional pugilist, need not concern us much, but perish the thought that modern civilization countenances any form of public amusement that may impair the futures of our best of young men, the college graduates!

MEDICAL SCHOOLS OF LOW STANDARDS.

The rapid development toward higher things in medical education during recent years is most gratifying. The future historian of medicine in this country no doubt will be struck with the general elevation of requirements for admission to medical study as well as the improvement and arrangement according to approved pedagogic principles of the medical curriculum that he will note have been and are taking place in so many medical schools of our time. It is probable, too, that he will trace much of this development to the influence of a few schools that had the wisdom to set their standards at what at one time may have seemed unattainable and impractical heights, but with the very practical outcome that there were disclosed a much greater number of young men anxious for that sort of a medical education than even the most sanguine enthusiast had anticipated. This gave medical educators the highest standards for actual comparison and not merely mediocre ones, and a general movement away from low standards started. This movement is still in its inception.

Much discussion of the many and difficult problems involved in a comprehensive elevation of the standards of medical education is still before us. The burning question for some time will be how best to deal with the manifestly inferior schools, the schools with low entrance requirements, low standards of teaching and low standards for graduation. The normal death rate among these institutions is still very small, but with a decreasing birth rate and, let us hope, a surely but slowly increasing death rate, their period of greatest harmfulness has probably reached its climax to enter on a gradual decline. There are, however, various methods by means of which the harmful influence of these schools can be curtailed still further.

In the first place it seems to us that the various state boards can do more than has been done to raise the standards of medical education of the applicants admitted to state examinations by specifying more exactly the minimum standards of entrance requirements to be adopted and followed by so-called recognized schools. Surely the very least that must be demanded by way of entrance requirements is a good high-school education or its equivalent, and after adopting some such standard, whatever it be, the higher the better, the state boards should demand that applicants for state examination furnish unquestionable proof of their having fulfilled this requirement before entering on the medical courses. In connection with this it must be said that high schools and other schools differ most widely in the quality of the work they do; hence the state boards should adopt regulations specifying exactly the amount and may be the kind of work that must have been done in order to satisfy their demands as to the applicant's fitness to begin the study of medicine. In the next place, the state boards could do a great amount of good by changing the character of the examination they now give applicants for license to practice. The examination now is written. The questions asked are such that the answers form no real test of the fitness to practice of those examined. A vigorous spell of cramming quiz-compends enables any medical student of ordinary mental ability to pass the examinations as now given in many states. As has been pointed out before in these columns, the examinations for license to practice should be practical; they should include practical work at the bedside, in the dissecting room and in the laboratory. The superiority of this kind of examination over the ordinary written examination in testing the real qualifications of applicants is so self-evident that no further discussion is necessary at this time.

Something would be accomplished, too, if the American Medical Association were to demand a certain definite minimum of premedical education as a qualification for membership after a certain period of reasonable length. This requirement would have manifold increased force if it were adopted also by the affiliated state societies and the respective local societies.

If decided steps were taken in the directions indicated the general effect would be, first, greater discretion on the part of medical students in the selection of the schools at which to take their medical courses; second, a determined effort on the part of the low-standard schools to rise from their present low estate, and in this invigorated process of differentiation the law of the survival of the fittest would be felt in full strength.

The discussions concerning the needed elevation of the standards of medical education in this country have dealt so far almost exclusively with the purely educational and technical features of the medical schools in preparing future physicians for their life work. It is to be hoped that some thought may be given also to the moral welfare of medical students. Will the moral atmosphere and influence of the low-standard school, especially in the large cities, be better or worse than that of the school with high educational standards? This is a question that medical men in general are competent to answer. Let each answer it to himself according to his light and use his influence accordingly.

TRUTH AND FALSEHOOD IN MEDICINE.

In a very interesting paper Dr. Richard C. Cabot[1] discusses the use of truth and falsehood in medicine. He calls it "an experimental study" and gives his own experience. It is generally held by physicians, we presume, that truth can not always be told, and many even hold that actual fiction is often justifiable.

There has developed a sort of popular medical casuistry which makes us sometimes step down from the high moral plane of absolute truth-telling as an almost necessary course of conduct. Dr. Cabot admits that he has told many lies that he has thought necessary, but he also shows from his own personal experience how practically useless this has been to him, and he has learned how much easier it is to tell the truth. The temptations to do otherwise are often great, and it would seem absolutely a risk in some instances to follow the straight path. Nevertheless he has found the innocuousness of truth, when reason and experience would lead one to believe it must do harm, more surprising to him than the remarkable tolerance of the febrile patient for alcohol. Of course, the truth does not necessarily always mean the blunt and naked truth, but simply the conveyance of a true impression and the avoidance of anything that is liable to produce a false one. It is not necessary to go at length into the details. The patients understand that themselves. They do not expect it. What we should do is make the patient understand in a general way the actual condition and at the same time to put before him the better possibilities. The confidence of the patient is a very important thing in medicine, and certainly that is not gained or retained if he finds the physician is withholding facts or trying to mislead.

A lie, understanding by this a misrepresentation intended to deceive, is an ugly thing to let loose, and one never knows what will be the consequence, especially the remoter ones. It is astonishing how negligent of this truth many people are and how much evil is being daily done by this negligence. One of the most striking instances of this, perhaps, which is not referred to by Dr. Cabot, is in the management of the insane. A large part of the difficulties and work of the physicians and asylum officers is in judiciously correcting false impressions which have been made on the patients before their admission. In many cases the after-effects can not be altogether removed.

There may be cases, Cabot admits, where patients do not react from the shock of the cruel truth, and he asks whether we are to persist in telling the truth, even when we believe it may kill the patient. His answer to this question seems perhaps a little harsh. He says, if it lay in our power to let loose in the atmosphere a poisonous gas that would vitiate the air so that the whole community would suffer in physical and moral fiber, would it not be worth a human life to save the whole community from such a deterioration. A lie seems to him to be something like that. We doubt whether many physicians will be in a position, even when they review all the facts of the case and look at it from a judicial standpoint, where it will seem necessary to them to often try to save a life by a lie or it will seem possible to them to prove that the truth can kill a patient. There are many ways of avoiding harsh truths and of so telling them that it will render them comparatively harmless. We have never yet been in a position where it seemed absolutely necessary and morally right, however convenient it might be, to tell a downright lie.

Dr. Cabot also extends his idea to deceptions in treatment, and urges the omission of placebos. No patient, he says, whose language we can speak or whose mind one can reach needs a placebo. He gives them now and then to patients with whom he can not communicate, but refuses to give them when an interpreter is to be had. He sums up the results of his experiments with truth and falsehood that he has not found the case where a lie did not do more harm than good. His belief is that anyone repeating the experiments will have the same experience. Truth-telling is not always so easy as lying, but its results are infinitely better. The article is one that could be well reprinted and circulated as a part of the ethical instruction of the candidates for medical practice.

1. American Medicine, February 28.

MENTAL CONDITION OF THE HABITUAL CRIMINAL.

While there are, unfortunately, some regrettable abuses in the good that the medical profession has accomplished by pointing out that crimes against life are often committed by those who are not responsible for their actions, there is no doubt that one of the greatest humanitarian advances of our time has been secured in this matter. Medical men must not be content with this, however, but must extend still further their influence over public opinion and legislative action so as to secure greater amelioration in a proper spirit of the present attitude toward the criminal and his punishment. Crimes against property are undoubtedly often committed by those who have no proper moral responsibility for their acts and who, though they may have to be taken care of by the state in order to prevent further depredations on the property of others, are yet in no condition of mind to deserve, or be benefited by, punishment properly so-called. For all punishment should imply at least the hope of reform, and many of those who commit crimes against property are incapable of moral improvement. This fact is recognized frankly with regard to certain classes of these unfortunate persons who are known as kleptomaniacs. But there are others for whom an improvement in the present legal method of treatment is specially eminently desirable and can probably only come through the wisely directed influence of the medical profession.

The histories of burglars and thieves are very common in the columns of our daily newspapers. It is unusual

to find an arrest made for a first offense. There is usually the story of previous crimes or robbery and of repeated convictions. Four or five previous convictions are not unusual, with several escapes from sentence because of legal quibbles, or because the injured party refuses to prosecute. In two recent cases of burglary that have been prominent in the newspapers each of the accused has been previously convicted in three of the large cities of the country. There is no doubt in the minds of those familiar with the psychology of criminals and their ways that when these prisoners have served the next sentence to be inflicted on them they will return to their old method of life. The fact of the matter is that they are not so constituted mentally as to be deterred by the disgrace of conviction for felony or be reformed by the supposed punishment of imprisonment.

A little over a year ago Sir Robert Anderson, K.G., who was for many years chairman of a parliamentary committee for the supervision of criminal affairs in England, deprecated this state of things in a striking article in one of the prominent London magazines.[1] He said:

> The widely circulated advertisement of one of the burglary insurance companies contains the startling statement that there are 70,000 thieves known to the police. I am speaking seriously and deliberately and I appeal to all who have any confidence in my judgment and knowledge of the subject to accept my assurance that if not 70,000 but SEVENTY known criminals were put out of the way the whole organization of crime against property in England would be dislocated and we should, not ten years hence, but immediately, enjoy an amount of immunity from crimes of this kind that it might seem Utopian to expect.

Almost needless to say, the same condition of criminal affairs holds in this country as in England. The measures of reform that Sir Robert suggests have as great an interest for us as for the people of Great Britain. His conclusion is:

> No one need be either a Solon or a Fouché to understand that if the fear of consequences will avail to deter from crime, the consequences should be made adequate to that end. And if there are those whom no fear of punishment will restrain, they should be treated as lunatics and caged in a suitable asylum.

The present trend of improvement in the treatment of criminals whose crimes are against property is towards the recognition of their previous record as the only possible method of determining an adequate sentence. After such a criminal has shown the virtual improbability of reform and the non-deterrent effect of punishment by a second offense of the same kind, he should never be allowed to be out of the close surveillance of the authorities until he has proved his capacity for moral reformation. A few years ago it would have seemed absurd to promise that the great commercial ports of the world could be made absolutely free from danger of invasion by such epidemic scourges as cholera and plague that had been so dreaded in the past. That promise has been fulfilled, however, by a careful investigation of the elements of danger and a rigid enforcement of the quarantine regulations necessary to secure cities against incoming infection. It looked originally as though all commerce would have to be excluded for a considerable time if security were to be assured during the prevalence of an epidemic. Now we know that a short detention of comparatively very few vessels gives absolute safety. So, too, it would seem that the frank recognition of the pathologic side of crimes against property would give a new aspect to the punishment of such criminals and the sequestration or persistent surveillance of a comparatively few criminal natures would give us almost complete relief from the worst of present conditions.

1. Nineteenth Century and After, December, 1901, p. 960.

CENTENARIANS IN THE UNITED STATES.

According to newspaper statements, the U. S. Census for 1900 finds 3,536 persons in the United States who are 100 or more years of age. The value of these figures may be questioned, and perhaps may be best estimated by the fact that 72.8 per cent. of the whole number are negroes, many of whom undoubtedly have but very remote ideas of their own age. There are persons of comparative intelligence who can take care of themselves in the ordinary pursuits of life in the society where they find themselves and yet have but the vaguest notions of their early years and of the date of their birth. We remember meeting one such person, not exactly a civilized individual, but an aborigine and one of sufficient intelligence and influence to be a sort of chief among his fellows, who, according to his own figuring, was 268 years of age, but actually was probably about 70. Probably many of the colored centenarians whose names have been collected by the census agents would reveal a similar state of things by careful examination. It seems improbable, too, that this country should have over 3,500 when Germany with a population of nearly 55,000,000 has only 778, and England with 32,000,000 only 146; and France with 40,000,000 has only 213. Among the foreign born the largest number of the alleged centenarians are Irish. Some aged Irish women (for most of these are females) have often a wonderful imagination, and sometimes their ideas are not entirely in accordance with facts. They may honestly believe that they are 100 years of age, but this does not prove it to be true. Of course, there are many centenarians, but each case should be thoroughly scrutinized and accepted only with strong corroborative evidence. While we have no doubt that the United States will show as many centenarians, and probably more, than most other countries, the census figures seem to us rather unreliable.

"DIED AS THE RESULT OF AN OPERATION."

How many people annually lose their lives because the popular dread of the surgeon's knife has prevented them from submitting to necessary operative treatment? Obviously it is impossible to answer this question with any certainty, for the number of patients who refuse operation after being informed of its necessity probably constitutes but a small fraction of the total, the larger part consisting of those who keep away entirely from the

physician, or who fly to the quack with whom "curing without the use of the knife" has always been the most alluring of baits. We have indeed heard of a widely advertised "eye specialist" who accomplishes feats in the way of straightening crossed eyes "without the knife" by simply using scissors, to which the knife-dreading patient readily submits. And how many patients will suffer terrific tortures from indiscriminating and ineffective caustics rather than undergo a painless operation under anesthetic for malignant growths? One of the many factors responsible for this mistaken fear has always seemed to us to be the frequent, almost constant form adopted by the lay press in reporting deaths following operative intervention of whatever kind, in the words: "Mr —— died yesterday as the result of an operation for," etc. In a great part of the cases the correct wording would have been: "Mr. —— died *in spite of* an operation," etc. For example, deaths following operation for appendicitis almost invariably are reported in the manner above described, although the operation for appendicitis *per se* would have but a most minute mortality. In many instances the error becomes extreme, as in the report of a death "from an operation for blood poisoning," when the operation in question consisted merely in draining the primary suppurating focus in the hand or foot. "Continual dropping will wear away," etc., and the natural outcome of the reiteration of this stereotyped expression is a popular misunderstanding of operative results that leads to a fear that is often fatal. Yet what can we say of the lay press in the face of the fact that the same unthinking phrase far from rarely makes its way into medical journals? If the operation did cause death, well and good—we wish nothing but the bare truth—but when death has been in spite of operation, and in many instances because this very fear has led to its postponement, then let us again have the fact stated truthfully and accurately.

THE "BATTLE OF THE CLUBS" IN GERMANY.

The Deutsche Aerztetag, which, we believe, is made up of delegates from the German medical unions (Aerztevereins), recently held a special (ausserordentliche) session at Berlin. It appears from the more or less complete reports published in the German weeklies, to have been of unusual interest. The subjects discussed were those relating exclusively to the material and social interests of the profession and largely matters concerning the German workingmen's relief and insurance associations (Krankenkassen) and actual and proposed legislation in regard to them and their relations to the profession. Evidently our German confrères have many reasonable grounds for complaint; the same tendency of the benefit societies to exploit the medical profession that is the cause of so much trouble in Great Britain is only too apparent in the German empire. Thousands of the Krankenkassen, according to one speaker, pay as little as 8, 6 or even 4 pfennigs for a physician's call. Over half of the Krankenkassen practice may be considered as charity work on the part of the physician, and most of these institutions have as their obvious object only the reduction of the physicians' fees. Instead, moreover, of being the resource of the really poor, to whom a reduction of the medical charges would be justifiable, these societies are utilized also by the well-to-do, thus defrauding the profession of its legitimate earnings. The Gera case, which has been mentioned in this journal two or three times, was, of course, discussed, as well as other attempts to degrade the profession by the association in these societies with quacks. Misleading statistics and misrepresentations in the press have helped to prevent the due attention of the legislators to the recommendations of the profession, and it was recognized that only through the organized effort of a united profession could the needed reforms be secured. The speakers saw encouraging signs in certain recent events, among them the Gera incident, the harmonizing of factions in the profession at Munich and its increased influence as brought out by thorough union and organization elsewhere. The discussion shows that the same problems exist in Germany as in Great Britain, and we can profit by watching how our brethren meet them in those lands. We have troubles of our own that we must meet in our own way, but there are others we share with the rest of the world, and it is only by organization and united effort that we can prevent the disastrous exploitation of the profession here that is already so strongly in evidence elsewhere. As we have said before, club practice is not yet a serious problem in this country except in a few localities, but it is a very threatening one.

Medical News.

CALIFORNIA.

Smallpox.—Smallpox is said to be raging among the Digger Indians of Long Valley and threatens to exterminate the tribe. ——A case of smallpox has been discovered at the Napa State Hospital.

Retired After Long Service.—Dr Charles A. Ruggles, Stockton, who has served for fifteen years as a member of the State Board of Health, and for four years as its president, was retired from the board recently by order of the governor.

German Hospital for Los Angeles.—The "Deutscher Hospital Verein" has recently been organized in Los Angeles, with Dr. Joseph Kurtz, president. The object of the organization is to build a new hospital in the city, using as nucleus $20,000 bequeathed for this purpose by Mrs. Werner, who died last year in Germany.

Split in Hospital Staff.—Four of the original incorporators of the Clara Barton Hospital, which was founded two years ago in San Francisco, owing, it is said, to disagreements regarding the management of the institution, have resigned. The new president is Dr. Emmet L. Wemple and the new secretary, Dr. J. Henry Barbat.

New State Board.—The new State Board of Health appointed by Governor Pardee met at Sacramento, April 1, and organized by electing Dr. Matthew Gardner, San Francisco, president, and Dr. Newel K. Foster, Oakland, secretary. The other members of the board are Drs. Oscar Stansbury, Chico; W. Lemoyne Wills, Los Angeles; Wallace A. Briggs and Aden C. Hart, Sacramento, and Martin Regensburger, San Francisco.

Under the Law.—G. W. Richmond, Los Angeles, a member of the "Anti-Drug Association," a magnetic healer and vice-president of the Spiritual Society of Truth Seekers, convicted of practicing medicine without a license, refused to pay the fine of $100, and languishes in jail.——The case against John Miller, alias "Dr. Miller the divine healer," of Bakersfield, charged with illegal practice of medicine, has been dismissed on condition of his leaving Bakersfield for ever.——Dr. J. Carl Bainbridge, Santa Barbara, charged with failure to report a case of contagious disease was found not guilty.——Dr. Samuel R. Chamlee, a "cancer specialist" of San Francisco, has been held to the Superior Court in bonds of $10,000 on the charge of manslaughter. It is alleged that while he was operating for cancer

he severed an artery and allowed the patient to bleed to death ——Dr. Sarah J. Tedford, San Jose, classified by "Polk" as a lung specialist, was acquitted on March 18 of the charge of practicing medicine without a state certificate.

ILLINOIS.

Epidemic at Greenfield.—It is reported that smallpox is epidemic in Greenfield, where 50 cases are said to exist.

Fee-Bill for Waukegan.—The physicians of Waukegan have formed a defensive union, with Dr. William C. Bouton, president, and Dr Edward F. Gavin, secretary, and have adopted a fee-bill.

New Hospital at Rockford.—The new St. Anthony Hospital, erected by the Sisters of St. Francis, at Rockford, at a cost of $50,000, was formally dedicated by Archbishop Quigley of Chicago, March 29.

Scarlet Fever, Not "Philippine Itch."—As certain citizens of Lake Forest have declared that the epidemic from which the town is suffering is a disease brought from the Philippines and transmitted from the troops at Fort Sheridan to the town, Dr. George W. Webster, president of the State Board of Health, and Walter S. Christopher of Chicago visited Lake Forest, examined a number of patients and pronounced the disease scarlet fever. The quarantine period has been extended until to-day. It is reported that there are 150 cases of the disease in Lake Forest and the neighboring towns.

Chicago.

Personal.—Dr. Theodore J. Bluthardt has been appointed United States Consul at Barmen, Germany.

Again Exonerated.—Dr. T. Jordan Balhatchett, who was acquitted of embezzlement, and was thereafter charged with larceny as bailee, was exonerated a second time April 2.

Mortality of the Week.—During the week ended April 4, 549 deaths occurred, equivalent to an annual death rate per 1,000 of 15 18, a substantial reduction from the high death rate of the previous week. Pneumonia again leads with 105 deaths; then follow consumption with 68; heart disease with 50; nervous diseases with 39; Bright's disease with 33 and violence with 31.

Influenza and Complications.—Regarding the influence of this disease on the mortality rate, the health department makes the following statement:

> Influenza has been more prevalent during the first four months of 1903 than at any time since 1891, and of the 350 deaths last month in excess of the number for March, 1902, 330 are shown by the physicians' certificates to be due—not to influenza direct, but to influenza as a fatally complicating cause of death from pneumonia, consumption, Bright's disease, heart diseases, bronchitis, measles and whooping cough, in about this order of frequency.

Deaths in March.—With one exception—that of March, 1895—last month's death rate was the highest since March, 1893, and the excess is accounted for by the mortality from influenza. The average March death rate for the previous ten years was 15.93 per 1,000 of population; for this March it was 16.94, or 6.3 per cent. higher than the ten-year average. In 1893 it was 19.18, in 1895 it was 17.88, and in 1899 it was 16.75 The total deaths from all causes was 2,703; 728 of these were under 5 years, and 573 over 60. Pneumonia heads the list with 582 deaths; consumption was the cause in 280 cases; heart disease in 207; violence in 153; Bright's disease in 142; nervous diseases in 132, and bronchitis in 127.

MARYLAND.

Baltimore.

The Deaths.—The deaths for last week were 187, 17.66 per 1,000; 20 were from pneumonia, 19 from consumption, and 5 from grip. One case of smallpox was reported.

Trachoma Excludes.—The special board of inquiry of the United States Immigration Bureau decided on the exclusion of 12 immigrants, with trachoma, who were landed here. They will be returned at the expense of the steamship company.

Toward Tuberculosis Sanatorium.—The Quarter Club has collected $3,000 toward the tuberculosis sanatorium and about $4,000 of the $25,000 necessary to secure a gift of $25,000 by some unknown benefactor has been raised. It has been determined to open a sanatorium in the Blue Ridge this summer, a cottage and a number of tents being used for the accommodation of patients.

MASSACHUSETTS.

Conditional Constitutionality.—The Supreme Court of Massachusetts has decided that their compulsory vaccination law is constitutional, but that a man who thinks vaccination is unnecessary can not be treated by force. He would, however, be liable to a fine of $5.00 for each such refusal.

Typhoid at Lawrence.—Lawrence, Mass., is in the midst of an epidemic of typhoid fever, apparently due to the practice of operators of the Pacific Mills of drinking unfiltered river water. This they do because the water running in the canal is cold, while that furnished for them to drink is unpleasantly warm.

Staff Changes.—The following changes have taken place in the staff of Noble Hospital, Westfield: Drs. George W. Brace and Fred. P. Lowenstein were appointed to the medical staff; Dr. James S. McLaughlin succeeded Dr. Edwin D. Hutchinson, resigned, on the surgical staff, and Dr. Hutchinson was appointed consulting surgeon

Dread State Institution.—The manufacturers of diphtheria antitoxin and vaccine virus have offered to furnish to the State Board of Health the products at a price lower than the cost of production to the state, and of a standard quality verified by governmental inspection, provided the legislature will refrain from appropriating money for a new state institution for their production.

Disease and Death in Boston.—For the week ended April 4 there were 214 deaths in Boston, an annual death rate per 1,000 of 19.04. There were reported 44 cases of diphtheria, with 3 deaths; 30 cases of scarlet fever; 20 of measles, with 1 death; 10 of typhoid fever, with 2 deaths; 18 cases of tuberculosis, and 24 deaths from this cause; 2 cases of smallpox, with 1 death. Pneumonia caused 29 deaths, whooping cough 8, heart disease 20 and bronchitis 5.

Street-Car Regulations.—Regulations forbidding spitting in street cars are common about Boston. Cambridge has taken another step: "Every street railway passenger car (closed) operated in Cambridge shall, while so operated, be properly ventilated; such cars shall be thoroughly aired at the end of each round trip; every such car shall be thoroughly cleansed at the end of each day's service and shall be disinfected once each week." A violation of these city ordinances involves a fine not to exceed $100.

NEW YORK.

The Situation at Ithaca.—The death-roll at Ithaca from typhoid fever now numbers 65. Only 3 new cases have been reported since the issue of last week.

Coroner's Bill.—At last, after a sensational political fight, the bill of Senator Elsberg, abolishing the office of coroner in New York City has been passed, and in its place is to come a system of medical examiners connected with the health department.

Prisoners Tuberculous.—Dr. Julius B. Ransom, physician of the Clinton State Prison, Dannemora, is reported to have said that one-fourth of the prisoners in that institution are afflicted with tuberculosis There are 250 prisoners thus affected, with hospital accommodation for only 54.

February Deaths.—The state health commissioner reports 10,826 deaths during February, which compares unfavorably with the average of 10,492, which has prevailed for the corresponding month in the previous five years. Influenza caused 1,500 deaths, pneumonia 1,223 and Bright's disease 802.

New York City.

Surgeon in Accident.—Dr. Francis W. Murray, one of the surgeons of the New York Hospital, narrowly escaped severe injury from the wrecking of his carriage by collision with an electric car. As it was, he received several minor injuries, and his coachman is not expected to live.

Ophthalmia Among Teachers.—It is said that two school teachers have developed a virulent and specific form of ophthalmia, supposedly from the handling of public school books. Details are lacking, but it seems strange that should be the case unless the same disease were very prevalent among the schools where the books are constantly handled by the teachers.

TENNESSEE.

Medical Staff Election.—The medical staff of Knoxville City Hospital met, March 23, and elected Dr. Benjamin D. Bosworth, president; Dr. Claudius M. Capps, vice-president, and Dr. Charles H. Davis, secretary.

State Board Examinations.—The first general examinations of applicants for license to practice medicine, since the law came in force, were held at Memphis, Nashville and Knoxville, March 30 and 31. About one hundred applicants were examined, fifty-nine of whom were examined in Nashville and thirty-two in Knoxville.

Medical Students Die.—Charles S. Lewis, one of the senior class at Chattanooga Medical College, recently died, and the combined classes of the college passed resolutions expressive of their sorow and eulogizing their deceased colleague.——Mr. Clements, a student in the medical department of the University of Tennessee, Nashville, died, March 10, aged 36.

Personal.—Dr. G. Chris Savage, Nashville, was operated on for appendicitis a few days ago and is making a good recovery. ——Dr. Fleetwood Gruver, Nashville, has been appointed assistant surgeon in the U. S. P.-H. and M. S. Service and assigned to duty at Port Limon, Costa Rica.——Dr. John R. Parker, Sideview, has been appointed assistant surgeon in the Navy with the rank of ensign.

Half a Century in the Society.—The Nashville Academy of Medicine and the Davidson County Medical Society gave a banquet April 7 in honor of Dr. Thomas L. Madden, Nashville, celebrating the completion of fifty continuous years of membership in the Tennessee State Medical Society. The committee in charge of the banquet consisted of Drs. W. Frank Glenn, D Bigelow Blake and Deering J. Roberts.

New Physicians.—The fifty-second annual commencement of the medical department of the University of Nashville was held March 31. Chancellor James D. Porter conferred the diplomas on a class of forty-nine and Hon. A. B. Anderson delivered the faculty address.——The University of Tennessee held its closing exercises April 3. A class of thirty-six was graduated. Dr. D. Bigelow Blake delivered the charge to the graduates and Gen. Harvey H. Hannah delivered the address of the evening.——Tennessee Medical College, Knoxville, graduated a class of eight, March 31. The charge to the graduates was given by Dr. Samuel L. Jones and the dean, Dr. Charles P. McNabb, conferred the degrees.——The medical department of Walden University, Nashville (Meharry Medical College), graduated a class of forty-one, March 2 President L. M. Dunton of Claflin University, Orangeburg, S. C., delivered the address of the evening. President J. Benson Hamilton conferred the degrees.

TEXAS.

Made Chief Surgeon.—Dr. James A. Moore, Marshall, has been made chief surgeon of the Texas and Pacific system, vice Dr. Benjamin F. Eads, Marshall, deceased.

Public Hospital at Waco.—The Sisters of Charity of St. Vincent de Paul have agreed on a site in Waco whereon they will build and equip a public hospital. The plans for the hospital are almost completed.

Hospital Car.—The medical department of the Southern Pacific has secured the car "Nacogdoches" and is having it fitted up as a hospital car. It will be kept in Houston, but will be ready to go promptly when and where needed.

Dallas Medical College.—The commencement exercises of the medical department of Trinity University, Dallas, were held April 1. A class of twenty-nine was graduated. Dr. Hugh L. McNew, dean of the faculty, presided and awarded the prizes; Rev. R. C. Kirkes, president of the university, conferred the degrees, and Rev. D. C. DeWitt delivered the address to the class.

VIRGINIA.

New Hospitals.—The new Protestant Hospital at Norfolk was opened to receive patients March 25. The formal opening will occur in about a week.——Winchester Memorial Hospital was opened March 18. Dr. Hunter H. McGuire is president of the institution.——Richmond Hospital, designed for the especial care and accommodation of colored patients, and purchased and equipped at a cost of more than $9,000, was opened for the reception of patients February 16

Personal.—Dr. Ballard R. Smith of Greenville, Va., has moved to Baltimore.——Dr. William Wertenbaker, physical director and laboratory assistant in biology at Washington and Lee University, has resigned and located at Ansted, W. Va. ——Dr. William F. Creasy, Newport News, has been appointed quarantine officer of the port, vice Dr. Samuel W. Hobson, term expired.——Dr. John T. Graham, Wytheville, fell recently in his office and fractured his arm.

Dr. Drewry Vindicated.—The Senate Committee on Public Institutions met March 26 and adopted a report in relation to the charges made against the management of the Central State Hospital, Petersburg, by Dr. Richard T. Styll, Newport News. The committee found that the charges were groundless and adopted resolutions praising the administration of the affairs of the hospital by Dr. William F. Drewry, the superintendent, and stating that the business and financial affairs of the institution have been administered in a way deserving of the highest commendation.

Eddyites and Osteopaths and Faith-Healers Defeated.—By the terms of a bill relating to the practice of medicine, as amended by the Senate and which the House passed with only one dissentient vote on March 27, healing by prayer for pay in Virginia will be unlawful and punishable by fine and imprisonment. Eddyites and osteopaths joined hands in the lobby for a bill amending the general law requiring the examination by the state medical board of all who practice medicine. The Senate's action of March 6 is a complete defeat for them. The Eddyites held that healing by prayer for pay should be licensed; the osteopaths wanted representation on the board, but failed to secure it.

GENERAL.

Mexico Quarantine Raised.—The quarantine against San Francisco has been raised by Mexico and many fully-loaded ships have hastened to resume the trade that had been interrupted. Guatemala has quarantined against all Mexican ports.

Diphtheria at Navy Yard.—An epidemic of a severe form of diphtheria has broken out at the Norfolk, Va., Navy Yard. One man has died, about 10 are sick and some 50 are suspects. There are 1,500 men on the receiving ships. Antitoxin is being freely used and all precautions taken.

Vigorous Plague Investigation in San Francisco.—A thorough exploration of Chinatown is being made by the allied health authorities. Drs. Glennan, Currie and Lloyd have had attacks of influenza, to which they were said to have predisposed themselves by their prolonged faithful work under unsanitary surroundings.

Diphtheria on Transport.—The long fight of the officials of the U. S. Transport "Buffalo" against the epidemic of diphtheria has ended. Over 150 out of over 400 were sick with the disease, but only 3 died. The outbreak was in December and the ship went to Port Royal, S. C., to establish quarantine and free the ship of the disease.

Mazatlan Plague Subsides.—On March 29 there were only 8 patients left in the lazaretto at Mazatlan. They are convalescing. The outbreak at Villa Union seems to have been suppressed, no case having occurred for almost two weeks. Two sanitary inspectors of the Mexican government were assassinated at Panuco, because of ignorant prejudice of the people.

CANADA.

To Limit Malpractice Suits.—The Council of Physicians and Surgeons of New Brunswick, acting for the New Brunswick Medical Society, has sent to the Provincial Legislature a bill with the object of securing a limit of one year to the time in which an action may be brought for injuries resulting from alleged malpractice.

Victoria, B. C., Isolation Hospital.—In 1902 the number of patients treated in the Victoria, B. C., Isolation Hospital was 92 and the total day's stay 2,101, as against 80 in 1901, with a total day's stay of 1,743. In 1901 the cost of nursing was $1,808.45, and in 1902 it was $3,274.75. The total cost of maintaining the Isolation Hospital was $9,279.44.

Banishing the Cigarette from Canada.—The cigarette was debated in the House of Commons during the past week, and apparently the cigarette must go, for a motion for the pro hibition of the manufacture, importation and sale of the cigarette was carried by a vote of 103 to 48. The motion simply points out public opinion on the subject, as the voting did not take place on any government legislation.

Physicians by Act of Parliament.—The "Montreal Star" states that a committee of the Quebec legislature is engaged in the benevolent task of making lawyers, druggists, dentists and physicians "by Act of Parliament." It is of course to be presumed that some of these rather fortunate individuals have found it inconvenient or impossible to pass examinations in the usual way, so they revert to the simple process of getting a bill passed by the legislature. Doctors "made-while-you-wait" is a dictum in Quebec which will no doubt produce a faction of strong force in opposition to the adoption of any such legislation as outlined in the bill now before that house seeking ratification of the Roddick law.

Regulations Concerning Diphtheria and Scarlet Fever in Ontario.—The Provincial Board of Health of Ontario has issued a special pamphlet to physicians calling direct attention to the acts as regards diphtheria and scarlet fever. As regards diphtheria the regulations require that all persons suspected of having diphtheria shall be promptly isolated until a swab has

proved the absence of the disease. Medical health officers are empowered to appoint sanitary policemen where necessary on the outbreak of either diphtheria or scarlet fever, and if these are not sanctioned by the municipality the Provincial Board of Health will then make the appointments. The minimum period of isolation for any case of scarlet fever is put at six weeks. In the case of diphtheria, the time limit shall be twenty-eight days unless swabs shall sooner show the absence of the disease.

Dominion Registration in Quebec Legislature.—Mr. Hutchison, M.L.A., has moved the second reading of his bill to amend the law regarding physicians and surgeons. It provides that whenever there is established under the Canada Medical Act of 1902, a register for Canada of medical practitioners under the said act, any person duly registered shall be deemed qualified and entitled to be registered in the Quebec register on payment of such fees as may be required In explaining the provisions of his bill, Mr. Hutchison said that there were French-Canadians all over Canada who wanted to have physicians of their own nationality and language, and that, therefore, Quebec province had more to gain by the measure than any other. The bill was opposed by Dr. Pelletier on the ground that it was not for the good of the profession and that the other provinces were not up to the standard of Quebec. This is as far as ratification legislation has got in the Quebec legislature.

FOREIGN.

A London Military Hospital, to cost over half a million dollars, is planned, because present quarters are not adequate.

Plague in Egypt.—A reappearance of bubonic plague is reported from some parts of Egypt and cholera is reported at Alexandria.

New Medical and Hospital Facilities at Copenhagen.—The Danish government has appropriated nearly $2,000,000 for the construction of a new general hospital and medical department for the university. The buildings are to be erected on a large plot of ground in the northern part of the city and to be completed in six years.

Endowments at Frankfurt for Scientific Purposes.—Nearly $200,000 has been collected for the erection of a zoologic museum and physico-chemical institute at Frankfurt a. M. This brings to $2,000,000 the total amount raised there during the last five years for the enlargement and endowment of scientific institutions connected with the scheme of a great university. The valuable land on which now stands the Senckenberg Hospital, etc., is to be sold and the city will donate lands on some of the newer streets in its place, which will add much to the fund.

Antituberculosis Serum from Fowls.—A prominent physician of Nimes, France, Dr. Viguier de Maillane, having been impressed by the resistance to human tuberculosis displayed by poultry, tested the serum from fowls and found that the Koch bacillus will not grow in it, while it has a marked protecting and attenuating effect on tuberculosis in guinea-pigs. After tests on himself and another healthy person to determine its harmlessness, he applied the serum as a therapeutic measure in six cases of tuberculosis. In a communication on the subject to the Paris Académie de Medecine, he reports that the serum had an unmistakably beneficial effect. Three of the patients were very much improved; two practically cured, and only one failed to benefit from the injections. The results indicate that this new serum is most effective in the torpid form of the disease, but that it acts like a powerful tonic in all cases, reducing the cough and expectoration and improving nutrition in general.

Campaign Against Charlatans in Germany.—During the recent trial of the magnetopath Pohl at Berlin, a number of witnesses testified that they had signed testimonials, stating falsely that they had been cured or wonderfully improved, in return for a reduction in the price of treatment. Pohl claimed to heal disease by his personal magnetism which he transmitted to the patient, assuming himself in return the disease. The suffering which this entailed on him compelled him to charge unusually high for his services, about $7.50 for a sitting. He also made use of carbonated baths. He was known to have received $200 from one consumptive who has since died. He was condemned, for "promising the impossible," to a fine of $250 and publication of the decision of the court. Our Berlin exchanges remark that it is a very significant fact that the newspapers which are read most extensively among the working classes entirely ignore these proceedings against charlatans which are written up in detail for the better class of lay papers.——The Posen courts have condemned a "Wonder Doctor," Scholz, to eighteen months' imprisonment for his quack practices and the injuries that have resulted therefrom.

Correspondence.

Michigan Students Protest.

DETROIT, March 24, 1903.

To the Editor:—In an editorial entitled the "Michigan Students' Protest," you took a most commendable view, but were misinformed about the students protesting. The students of the Detroit College of Medicine are in favor of the bill, and I understand that the students of Michigan University at Ann Arbor are also. In fact, the students of reputable colleges have no fear of being able to pass, and are always in favor of a higher standard. J. H. CARSTENS.

To the Editor:—In view of the editorial which appeared in THE JOURNAL, March 21, we wish to state that we regret sincerely that the article was so worded that the impression might be given that the medical students of the University of Michigan are opposed to the passage of the Nottingham bill.

We wish to state that the medical students of the University of Michigan have done nothing, either collectively or individually, to oppose this bill or any of its provisions.

Furthermore, we are unanimously in favor of any means which will tend to raise the standard of medical practice in Michigan, and, believing that the Nottingham bill, if enacted, will have this effect, we are heartily in favor of its passage.

Unanimously adopted by class of 1903. President, F. C. Penoyar; secretary, Maude G. Hinman.

Class of 1904. President, W. A. Scott; secretary, Curtis Evans.

Class of 1905. President, C. W. Merkel; secretary, D. E. Burnett.

Class of 1906. President, J. F. Hastings; secretary, Z. K. Brinkerhoff.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

THE SOURCE OF VACCINE.

EVANSVILLE, IND., Feb. 27, 1903.

To the Editor:—From what source do vaccine laboratories or vaccine farms obtain their original vaccine virus? Do they use the smallpox lymph, or the cowpox lymph, which comes originally from the "grease heal" of the horse? A scientific question of inestimable value is herein to be considered and should be known by every physician. The safe preventive from smallpox would be to vaccinate with the vaccine obtained from cows that had been inoculated by lymph originally obtained from smallpox. F. L. DAVIS.

ANS.—Following the receipt of the above, we wrote to a number of manufacturers of vaccine and quote below from certain of their replies.

The H. K. Mulford Company stated that vaccine virus employed by them is obtained at short intervals from several sources, namely:

"The Jenner Institute of Preventive Medicine, London, England; Chambon & Menard, Paris, France; Institute Vaccinale, Berne, Switzerland; Pasteur Institut, Lille, France, and in addition to these from two sources in the United States. The vaccine virus on receipt is tested and those strains which produce the most typical physiological effect are used in propagating the virus."

Parke, Davis & Co. said: "Our seed vaccine we have obtained from different sources, chiefly European. We have secured various supplies from the Imperial Vaccine Institute of Vienna. Some of the best seed has come from the fine establishment conducted at Berne, Switzerland. All the seed used by us has been, we are perfectly sure, the product of the calf or heifer—not in any instance the virus obtained from human smallpox pustules.

"It is, however, our conviction that smallpox and cowpox are one and the same disease, manifesting itself differently in the two animals under the profoundly modified biological conditions—smallpox in the man, cowpox in the animal. Several German investigators have repeatedly succeeded in directly inoculating calves with the human virus, thus obtaining bovine vaccinia which has in turn produced in human beings perfectly normal vaccinations, affording full protection. The great English authority, Copeman, stated last summer in person to our Dr. Houghton that he had repeatedly inoculated monkeys with the virus of human smallpox, passing it along from one monkey to another, and with the virus thus obtained he has produced in calves genuine vaccinia vesicles, the pulp of which has proved an effective means of inoculating and

protecting human beings. Copeman added that hundreds of people vaccinated with lymph obtained from calves which in turn had been inoculated with virus secured from these monkeys, had exhibited typical 'takes' and many of these people had been subsequently exposed to smallpox without contracting the disease—a fact which would seem to establish the immunizing power of the particular lymph. Clearly, then, cowpox is the result of the direct introduction of smallpox virus into the animal organism, or else the two parallel maladies emanate from the same common cause. The identity of their source is to our mind established by the great preponderance of evidence and authority."

Frederick Stearns & Co. say:

"The original source of our vaccine virus was from vaccine obtained from heifers that had been previously inoculated with smallpox lymph taken from a human being and that too, not indirectly as from cow-pox or from 'grease heal' in some mysterious roundabout way, but directly from human being to heifer, thus modifying it by its passage through the bovine so that it will no longer produce smallpox by direct contagion, but a modified form of it known as vaccine vesicle which confers immunity to the smallpox disease.

"There may be a natural cow-pox, but in our opinion there is no such thing as a cow-pox which will confer immunity to smallpox which had not originally the human source, and as for 'grease heal' it is utterly absurd and unscientific to think of such a thing. We think you will find that the best authorities and the best masters of the art agree with us on this point."

H. M. Alexander denies most emphatically that vaccine is cowpox and affirms that cow-pox is smallpox. He says further:

"My experiments proved to me beyond any reasonable doubt that vaccine virus was simply smallpox passed through the cow and that it was at first very weak in its action, the first animal inoculated from smallpox direct always taking in a very uncertain manner; but the contagious character so far as the human family was concerned was lost at once. When passed through a second animal it began to assume many of the characteristics of the vaccine disease as seen in the stables. The third and particularly the fourth in all instances was so characteristic of kine pox that it was used and successfully used in a great many experimental cases.

"My continued experience with horse grease has caused me to believe that there is no such thing as horse-grease cow-pox; or, if there is, then the horse grease as we know it to-day is not the horse grease referred to by Jenner."

DYNAMITE HEADACHE.

RUSSET, W. Va., March 26, 1903.

To the Editor:—In your query column, I should be obliged if you would suggest some remedy for what is known here as "dynamite headache." This is caused by the inhalation of the fumes from the dynamite which is used in blasting. I have tried acetanilid in doses of 7.5 to 10 grains combined with caffein cit. and monobromate of camphor, but in a great many cases this has no effect and I am compelled to use morphin before any relief is obtained.

JOHN W. BROWN.

ANS.—On the theory that dynamite cephalalgia is a congestive headache due to vasomotor (arterial) paralysis of the cerebral vessels, hypodermic injections of ergotin, atropin and strychnin, and cold applications to the head have been recommended. The best remedies, however, according to Key (Oliver: "Dangerous Trades," p. 614) are strong coffee, and a linseed poultice to the back of the neck. This is probably a deduction from practical experience, and there may be still others used in dynamite works. Most persons soon become habituated to the fumes and cease to suffer, but there is a great difference in the susceptibility of different persons. We would not suppose acetanilid to be a very satisfactory remedy.

State Boards of Registration.

New Law in Nebraska.—A new law has just passed the Nebraska legislature which requires an examination as well as a diploma, of all applicants for license to practice medicine in the state. Heretofore a diploma from a recognized and approved college was all that was necessary. We shall publish a full abstract of the law next week.

Alabama Law.—The recent law defining the divisions of practice and exemptions from examination therein in Alabama is as follows:

An Act to prescribe the branches of medical learning upon which applicants for the privilege of treating the diseases of human beings in this state must be examined, and to provide for the issuance of certificates of qualification therefor.

Section 1. Be it enacted by the legislature of Alabama, That any applicant for a certificate of qualification to treat the diseases of human beings by any system of treatment whatsoever shall, according to rules prescribed and standards established by the Medical Association of the State of Alabama, be examined by one of the authorized boards of medical examiners of this State in the following branches of medical learning, to-wit: Chemistry, anatomy, physiology, the etiology, pathology, symptomatology and diagnosis of diseases; obstetrics and obstetrical operations, gynecology, minor and major surgery, physical diagnosis, hygiene, and medical jurisprudence, and should said applicant be found proficient in said branches of medical learning a certificate of qualification in such form as shall be prescribed by the said Medical Association of the State of Alabama shall be issued to him, which shall entitle him to treat any and all diseases of human beings in this state in any manner that he may deem best.

Sec. 2. Be it further enacted, That when any applicant states in writing that he has neither studied nor proposes to practice major surgery, said applicant shall be exempt from examination in said branch of major surgery, and should he be found proficient in other branches of medical learning named in Section one (1) of this Act that a certificate of qualification in form to be likewise prescribed by the Medical Association of the State of Alabama shall be issued to him, which shall entitle him to treat all diseases of human beings in this state in such manner as he may deem best except by the practice of major surgery.

Sec. 3. Be it further enacted, That all laws and parts of laws in so far as they conflict with the provisions of this act be and the same are hereby repealed.

Marriages.

R. B. BELL, M.D., to Miss Julia M. Stewart, both of Nashville, Tenn., March 26.

ROBERT M. STONE, M.D., Omaha, Neb., to Miss Belle Noxon of Bee, Neb., April 5.

EDGAR M. HERMANCE, M.D., to Miss Mary Ellerington, both of Yonkers, N. Y., March 27.

MEYLER D. GIBBS, M.D., Willow, N. M., to Miss Grace Wilson of Colorado Springs, Colo., March 9

D. EDWIN STONE, JR., M.D., Emmitsburg, Md., to Miss Elizabeth Hammond Downey, at New Market, Md., March 25.

Deaths.

James A. Steuart, M.D., died at Baltimore, from pneumonia, March 27, aged 74. He was the son of Dr. Richard Steuart, founder of Maryland Hospital for the Insane and grandson of Dr. James Steuart, a graduate of Edinburgh University. Dr. Steuart graduated in medicine from the University of Maryland in 1850. From 1850 to 1854 he was physician to the Baltimore General Dispensary and from 1854 to 1861 assistant physician at the Maryland Hospital for the Insane. From 1873 to 1889 he was health commissioner of Baltimore, and by his energy was instrumental in arresting several threatened epidemics of smallpox and yellow fever. He was secretary of the State Board of Health from 1894 to 1897. He was surgeon to the First Maryland Infantry, a member of the American Public Health Association and of the Medical and Chirurgical Faculty of Maryland.

John P. Wood, M.D. Transylvania University Medical Department, Lexington, Ky., 1828, the oldest practicing physician in the United States, if not in the world, of Coffeeville, Kan., died at the home of his brother in Thomas, Okla., March 28, from paralysis, after an illness of one week, aged 101 years, 2 months and 24 days. Dr. Wood served as surgeon of Henry Clay's regiment in the Mexican War, in which he was seriously wounded. At the close of the war he settled in Danville, Ill., and in 1853 moved to Kansas.

Goronwy Owen, M.D. University of Pennsylvania, Philadelphia, 1857, professor of obstetrics and diseases of women and children, Medical College of Alabama, a surgeon in the Confederate Army during the Civil War, a recognized authority on obstetrics, died at his home in Mobile, March 30, from paralysis, aged 69.

Frank Van Schoiack, M.D. University Medical College, Kansas City, Mo., 1901, for many years at Ottawa, Kan., more recently at Ponca City, Okla., died recently at the latter place, from pulmonary tuberculosis, following pneumonia.

James Jones Singer, M.D. Jefferson Medical College, Philadelphia, 1871, for 26 years surgeon of the Baltimore and Ohio Railway at Connellsville, Pa., died at his home in that place, March 28, after a long illness, aged 53.

Donald Gilbert Gordon, M.D. Trinity Medical College, Toronto, 1886, professor of hygiene in Trinity Medical College, died at Church Home Hospital, Baltimore, March 28, aged 44, of tubercular peritonitis.

Walter S. Leaming, M.D. Jefferson Medical College, Philadelphia, 1882, postmaster of Cape May, N. J., formerly state assemblyman and senator, died at his home in Cape May, March 30, aged 48.

Richard Johnson, M.D. Harvard University Medical School, Boston, 1865, ex-president Prince Edward Island Medical Society, died suddenly a few days ago at his home in Charlottetown, P. E. I.

George B. Mott, M.D. College of Physicians and Surgeons of Ontario, Toronto, 1869, who practiced for a number of years at Petrolea, Ont., died at Wallaceburg, Ont., January 17.

W. Frank Lee, M.D. Kansas City (Mo.) Medical College, 1900, of Beatrice, Neb., died at Las Cruces, N. M., March 23, from tuberculosis, after a long illness, aged 26.

Andrew Halliday, M.B. Glasgow University, 1891, associate professor of pathology in the Halifax Medical College, died at Halifax, from tuberculosis, March 10, aged 36.

George H. Perrin, M.D. University of Maryland, Baltimore, 1895, died from diabetes, March 30, at his home in Durand, Mich., after an illness of one month, aged 35.

David H. Stever, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1876, died from pneumonia, at his home in Fairfield, Iowa, March 26, after a short illness.

Robert M. Bostwick, M.D. University of Louisville, 1857, a veteran of the Civil War, died at his home in Memphis, Tenn., March 28, after a brief illness, aged 69.

William H. Tutt, M.D. Kentucky School of Medicine, Louisville, 1890, of Campton, Ky., died from paralysis at Jackson, Ky., after a short illness, March 31.

Robert M. Cooper, M.D. Western University Medical Department, London, Ont., 1889, of London, Ont., died suddenly, March 21, from epilepsy, aged 33.

George Stewart, M.D. University of the Victoria College, Cobourg, Ont., 1869, of Port Rowan, Ont., died January 28, from apoplexy, aged 62.

A. M. F. Hawkins, M.D. Atlanta (Ga.) Medical College, 1876, died at his home in Ball Ground, Ga., March 29, from pyemia, after a short illness

Kenneth D. McKenzie, M.D. Halifax (N. S.) Medical College, 1887, Medical Health Officer of St. Johns, Newfoundland, died December 24, 1902.

Alvin W. Tyler, M.D. St. Louis Medical College, 1878, died at his home in Tulare, Cal., March 18, from heart disease, aged 71.

Deaths Abroad.

Dr. Salomon, vice-president of the Union des Syndicats Médicaux de France and author of a number of works on trade intoxications, etc., died at Savigné.

J. Deutsch, M.D., publisher of the "Aerztliche Zentralzeitung at Vienna.——**Dr. J. Gine y Partagas,** professor of pathology at Barcelona.——**Dr. Didiot,** formerly chief of the French military sanitary department.

E. Bottini, M.D., Pavia, professor of surgery at Pavia and senator of Italy, died at his villa at San Remo, March 11, aged 66. His family is indissolubly connected with the Bottini operation, and he was one of the most advanced surgeons of his day and country.

G. Bouilly, M.D., professor agrégé of surgery at Paris, died in that city, March 14, aged 55 He had the reputation of being the busiest surgeon in Paris, and was appointed president of the Société de Chirurgie last year. Abdominal surgery and gynecology were his specialties and he was a frequent contributor to medical periodicals devoted to these branches.

Miscellany.

Hydrophobia.—From the extended comment recently in the public press one might infer that there was a genuine epidemic of rabies in New York City. Such is not the case, although special attention has been directed to the fact that this disease is present at all seasons by the recent sad death of Dr. H. P. Loomis' child. According to the statistics of the health department, there have been, on an average, in recent years about 7 deaths annually from hydrophobia. On the other hand, Dr. H. D. Gill, a veterinary surgeon, asserts that the dumb form of rabies is quite common among animals, and that unless it happens that a person has been bitten by an animal so affected the case does not come to the notice of the board of health laboratory. He finds that about a dozen cases of rabies were observed in the past year by each of several well-known veterinarians. Because of the rarity of the disease in the human being very few physicians have had an opportunity of becoming familiar with its symptomatology. To facilitate the detection of rabies in dogs Dr. Gill offers the following suggestions:

> Beware of a dog when it becomes dull and hides away; appears restless; always on the move and prowling; whose countenance is sombre and sullen; walks with head down like a bear. Beware of one who barks at nothing when all around is still. Beware of a dog that scrapes incessantly and tears up things. Look out for the dog which has become too fond of you and is continually trying to lick your hand and face. Beware above all of the dog which has difficulty in swallowing, which appears to have a bone in its throat, and one that has wandered from home and returns covered with dirt, exhausted and miserable.

It is generally agreed, says Dr. Gill, among physicians who have studied the subject, that the disease is readily controlled by the enforcement of a muzzling ordinance, but unfortunately the control of dogs in New York City is in the hands of the Society for the Prevention of Cruelty to Animals, whose president declares that, in his large experience of thirty years, he has not seen a single case of rabies, and that muzzling a dog makes him sick and cross and much more likely to bite.

American Medical Temperance Association.—The twelfth annual meeting of this association will be held in New Orleans, May 6 and 7, 1903, each session beginning at 9 a. m. An address will be given by the honorary president, Dr. N. S. Davis, Chicago, and the annual address by the president, Dr. Winfield S. Hall, Chicago. Papers will be read by Dr. H. O. Marcy, Boston; H. D. Didama, Syracuse, N. Y.; J. W. Grosvenor, Buffalo, N. Y.; T. D. Crothers, Hartford, Conn.; T. A. MacNichol, New York; C. E. Stewart, Battle Creek, Mich.; John Madden, Milwaukee, Wis.; D. S. Reynolds, Louisville, Ky., and others. This association was organized in Washington, May 7, 1891, and holds its annual meeting at the same time and place as the American Medical Association The following extract from the constitution of the Association will indicate its plan and purposes:

> The object of this association is to encourage and promote the clinical, therapeutic, pharmacologic, and chemical study of alcohol in health and disease. It also aims to gather, compile, and make available the studies and experiences of medical men in all parts of the country concerning the use of alcohol and to formulate such definite facts as can be utilized and made available in the practice of medicine. It is assumed that all physicians interested in the study of alcohol should approach it from the scientific side alone, unbiased by any personal considerations of custom or habit, and with no object other than to ascertain the facts concerning this question irrespective of all possible conclusions. This is the spirit and purpose of the association, and it is entirely independent of any other object except the purely scientific question of the nature and character of alcohol.

All regular practitioners of medicine may become members by making application to the secretary. It will be evident to every one that the field of this association is rapidly widening and the demand for studies in this direction is constantly increasing. A very cordial invitation is extended to all persons interested in this subject to unite with this organization and lift the whole subject out of the plane of quackery into the atmosphere of clear science. All communications addressed to the secretary, T. D. Crothers, M.D., Hartford, Conn., will receive prompt attention.

CLIPPINGS FROM LAY EXCHANGES.

Easter Lays.

MASSAGERY IS GOOD.

"Dr. —— has removed her massagery and beautifying business to Chicago, where a wider field awaits her."—"Monroe (Wis.) Sentinel."

WANTED—A DOCTOR TO BURY.

"We are hoping a lively hustling 'Doc.' will settle in our township. Our much lamented citizen Doc —— was buried over a year ago and we think it a good place for one."—Tylersville Topics, "Oneida (N Y.) Despatch."

GASTRIC VISCERA RUPTURED.

"August —— was kicked in the abdomen by a horse on Tuesday and is in grave danger of losing his life. . . . A severe rupture of the internal organs of the stomach is feared and an operation will be necessary."—"Denver Times."

WHY NOT RIDE?

"Dr. ——, we understand, has been made a member of the International Medical Congress, which meets in Madrid, Spain, in April. The doctor says he will be unable to go, on account of the bad condition of the roads."—"Tell City (Ind.) Journal," March 18, 1903.

PIE BACTERIOLOGY.

"Dr. Klein is an expert on the Government Medical Board. After investigating pies on behalf of the Government he reports: 'All contained the spores of anaerobic non-pathagenic bacillus balyricus, the spores of bacillus mesentericus vulgatus and slaphylococcus albus of at least two different kinds.'"—"Wilmington (Del.) Republican."

IMPORTED FÆCES, ET AL.

The program of the twenty-eighth semi-annual meeting of the District Medical Society of Central Illinois, as published in the "Jacksonville (Ill.) Courier," Oct. 30, 1902, contains the following interesting titles of papers: "Esfilogg of Typhoid Fever; Saconea; Serrectory Neuroses of the Stomach; Prostateeromy; Leukemia and Pesendo Lukemia; Imported Fæces; Theuterine Curelte; Notes from New York Roby Clinic."

COMPLETE GASTRO-ENTERECTOMY.

In a report of a gunshot-wound case, the "Norfolk (Va.) Despatch" thus describes the operation. . . . "The stomach and bowels were taken completely out of the negro, all of the food was taken from the stomach and the perferaations in it dressed. The stomach was then put back in the body and the incission through which it was taken out stitched up, leaving a short opening through which the wound might be allowed to bleed."

FOREIGN BODIES IN THE LEGS.

The following advertisement appeared in the "Westminster Gazette," last September: "An aged Gentleman (widower, no children) will be requiring soon an experienced Pensioned Army or Navy Valet. His health is perfectly good, but he has been severely injured by the upsetting of an express train in his legs. He wishes help when he gets out of his bath, and dresses, and also in undressing at night. Any applicant must be a member of the Church of England, and state whether married or single.—Apply, &c."

PULMONARY JERKS.

"Shot Through Air with Bullet's Speed—Man's Lungs Were Jerked From Their Fastenings—Pneumonia Developed in Few Hours—Victim Lives. The condition of —— who fell from . . . railway train . . . presents an interesting study. . . . The young man was injured internally and in an extremely unusual way. His lungs were literally torn from their fastenings, besides other injuries received. . . . His frontal bone was fractured. . . . In addition . . . his inner organism was badly shocked, particularly his lungs."—"Atlanta (Ga.) Journal."

NATIONAL MEDICINE AND FOOD BUREAU.

Proposed to Secure Pure and Honest Drugs, Chemicals and Foodstuffs.

The following statement in regard to the proposed National Bureau of Medicines and Foods has been sent us by those who have been giving the matter thought: The subject will be brought before the House of Delegates of the American Medical Association at New Orleans by a provisional committee appointed for the purpose of enquiring into the subject. The committee consists of Drs. E. Eliot Harris, New York; Solomon Solis Cohen, Philadelphia; N. S. Davis, Jr., Chicago; H. Bert Ellis, Los Angeles, and Philip Mills Jones, San Francisco.

The idea of establishing a board of qualified experts who should represent the interests and the support of the professions of medicine and pharmacy, and through the medium of such a board secure: 1. More general conformity to the standards of the pharmocopeia; 2, drugs, chemicals and foodstuffs that will be actually as labeled and can be relied on; and 3, deal in a proper professional and ethical manner with the large and ever-increasing number of proprietary preparations and mixtures that are being presented to the medical profession, was first suggested by Dr. F. E. Stewart at the meeting of the American Medical Association in 1881.

This idea has been elaborated and plans have been formulated which it is thought will secure the objects desired. These plans have been approved by a number of representative manufacturers, physicians and pharmacists, and it is evident that if the professional interests and the people of this country (and especially the members of the American Medical and the American Pharmaceutical Associations) really desire relief from the present unfortunate and distressing condition of materia medica and pharmacy, and of adulterated and dishonest foodstuffs, such relief is at hand.

Primarily, this plan contemplates the voluntary association of honest manufacturers and pharmacists who will agree with the board of experts representing pharmacy and medicine, on standards of identity, purity, quality and strength, to which their products shall comply, and will further agree to carry out these standards and to comply with the necessary rules governing manufacture, etc.

Organization for the purposes indicated will be begun by the formation of a corporation on the membership plan—no stock issued and not for profit—under the name of the National Bureau of Medicines and Foods, and all the members of the American Medical and the American Pharmaceutical Associations are made members of this bureau. It is proposed that the board of directors governing this bureau be elected by these two associations, each having five directors, one from each association retiring annually and a successor elected for five years.

In order to indicate to the physician, the pharmacist or the purchaser such articles as comply with the standards of identity, purity, quality and strength, and may, in consequence, be relied on to conform truthfully with the labels affixed, and also to reward the honest manufacturer and pharmacist for his honesty and aid him in competition with dishonest or impure products, those manufacturers and pharmacists who affiliate with the bureau in this work will be authorized to print on the label of such of their products as are placed under the supervision of this bureau a certificate of identity, purity, quality and strength, of a form to be indicated by the board or directors.

All possible precautions in the way of frequent inspection, analysis or assay will be taken by the bureau in order to keep certified products up to the standard and to protect the bureau certificate from fraud. In addition to the original analysis of each "batch," every article bearing the bureau certificate will be purchased in open market from time to time and submitted to analysis, assay or comparison with standard samples.

The bureau will also gather and diffuse reliable information relative to materia medica products, chemicals and foodstuffs and to those who manufacture or deal in the same, and it is believed that in a comparatively short time such information will replace and do away with the one-sided and unreliable trade literature, which is at present, in many instances, the only available source of information.

The work of the bureau will be purely commendatory and not in any way condemnatory, so that it can in no event become an agent of blackmail.

As the bureau is not a commercial enterprise, is not organized for profit nor for money making, only the actual expense of doing the work required will have to be defrayed. It is proposed to assess this actual cost on the various manufacturers and producers whose goods are certified by the bureau, each in proportion to the amount and value of the goods so certified. This feature of the plan has been considered satisfactory by those who have signified a willingness to affiliate with the bureau.

In addition to the two associations already mentioned, any scientific society that may vote to affiliate with the bureau may do so, and its members then become members of the bureau; and, further, any person who so desires or who is willing to signify his approval of the aims and objects of the bureau, may become a member on the payment of $1 per year.

CERTIFICATE OF INCORPORATION.

We, the undersigned, all being persons of full age, and at least two-thirds being citizens of the United States, and at least one of us a resident of the State of New York, desiring to form a corporation, pursuant to the provisions of the Membership Corporations Law of the State of New York, do hereby make, acknowledge and file this certificate for that purpose, as follows:

First. The particular object for which this corporation is to be created is: To determine on and fix standards of identity, purity,

quality and strength and to secure adherence to prescribed formulas of all drugs, chemicals, foodstuffs, and of all articles intended for use in the arts and sciences or for human consumption; to diffuse accurate and reliable information as to such articles, preparations or products and as to those making or dealing in the same; to procure uniformity and certainty in the customs, usages and methods of manufacture of those engaged in the foregoing or allied trades; to supervise the manufacture, preparation or production and distribution by its members of all commodities, articles or preparations mentioned, and, on sufficient evidence that the standards of identity, purity, quality and strength, as well as adherence to prescribed formulas have been maintained, and that all requirements for manufacture, preparation or production, as set forth in the by-laws, rules or regulations made and provided have been complied with by the member manufacturing, preparing, producing or distributing such commodities, articles or preparations, to issue to such member a certificate of identity, purity, quality or strength and compliance with prescribed formulas, which certificate shall be of the form and nature and shall be used in the manner set forth in the by-laws, rules or regulations for that purpose made and provided; provided, however, that no medicinal preparation shall be so certified unless the formula, couched in the ordinary terms of chemistry and pharmacy, and giving the qualities of the active ingredients, shall have been or shall be published; to settle differences between its members, and to promote a more friendly intercourse between business men and between its members; to aid, stimulate and encourage research, investigation and study that will tend to enlarge, improve or increase and diffuse knowledge and information of materia medica, chemistry, pharmacy, pharmacology, pharmacognosis, pharmacodynamics, therapeutics and all arts and sciences allied thereto.

Second. The name of the proposed corporation is the "National Bureau of Medicines and Foods."

Third. Its principal office is to be situated in the City of New York.

Fourth. The number of its directors shall be ten.

Fifth. The names and places of residence of those persons to be its directors until its first annual meeting are as follows:

Sixth. The annual meeting shall be held on the ————.

Book Notices.

The Proceedings of the Charaka Club. Volume I. 8vo. Pp. 97. Price, $3.50 net. Printed for the Club by William R. Jenkins. New York: William Wood & Co. 1902. Limited Edition.

One of the most select clubs of which we have read was the X Club founded in 1864 and which existed for twenty-nine years. It consisted of Huxley, who was responsible for its creation; George Burk, secretary of the Linnear Society, and at one time president of the Royal College of Surgeons; Edward Frankland, the chemist; Hirst, the mathematician; J. D. Hooker, the great botanist; Sir John Lubbock, William Spottiswood, Herbert Spencer and John Tyndall.

These nine at one time tried to elect a tenth member, but failed, hence probably it was called the X Club. Huxley called it a scientific caucus or ring, but that it had no raison d'être beyond the personal attachment of its original members.

The Charaka Club goes the X Club one better, as far as the number of members is concerned, for it has ten. They are Drs. Pearce Bailey, John S. Billings, John Winters Brannan, Joseph Collins, L. Dana, Arpad G. Gerster, Ward A. Holden, Frederick Peterson, B. Sachs and George F. Shrady, with one lonesome honorary member, William Osler. The raison d'être is "a number of medical men of this city who were interested in the literary, artistic and historic aspects of medicine, and who hoped to find some recreation, if not profit, in dealing with this, the less serious, side of their art," concluded to be a club. We are not told that one of the objects is the publication of books, but its first venture in this line is before us, and it is something of which its members may be proud, not alone for its value from the literary viewpoint; but for its uniqueness and for its typographic make-up.

The first article is on Hindoo Medicine. In this Dr. Sachs tells us about the medicine of the Hindoos, and presents a very interesting, although brief, account of our professional Indian brethren of long ago. The club was named after one of the Hindoo medical writers, Charaka, whose work is still extant and from which Sachs quotes freely. Three poems by Peterson follow, one on "Heredity," one on "Environment," and one on "Solitude." A. G. Gerster writes "On the Hippocratic Doctrine of the Injuries of the Cranium." Dr. Dana tells us about Æsculapius, giving a biographic sketch, as it were, "correctly as anything not the least true can be correct." This article is accompanied with fifteen full-page plates illustrating the statues, etc., of the God of Medicine, together with a double-page plate showing "The Hieron, or Sacred Grove," and two half-page plates of the Temple of Æsculapius at Epidauros. Dr. Dana also writes very entertainingly of "The Evil Spoken of Physicians," and makes some happy quotations. He thinks that our profession is not deserving or receiving as many gibes as has been the case in the past.

Dr. Collins makes two contributions: one about a man who was in love with his typewriter, and didn't know it. He wanted Collins to hypnotize her, and although he, Collins, cruelly refused to do so, nevertheless charged him for doing it. The other contribution is also a story of love, but not a love story, and bears the title "A Contribution to Ethics."

"The Ophthalmology of the Greeks," by Dr. W. A. Holden closes.

The book is issued in a limited edition, of which only 257 copies are for sale.

Twentieth Century Practices. An International Encyclopedia of Modern Medical Science, by Leading Authorities of Europe and America. Edited by Thomas L. Stedman, M.D., New York City. Volume XXI. Supplement. Cloth. Pp. 845. Price, $5.00. New York: Wm. Wood & Co. 1903.

While only two years have elapsed since the completion of this series the advances have been sufficiently marked in many branches in medicine as to justify already a supplementary volume. In this one the articles have been prepared by men of first-class standing, Europe as well as America being liberally drawn on. As instances of this we may note Carl Beck on the Roentgen ray, Reginald Harrison on kidney disorders, Lydston on prostatic and urethral diseases, von Noorden on diabetes, Allen on skin diseases, Einhorn on diseases of the stomach, Vaughan on ptomains, toxins, etc., Sternberg on yellow fever, Shiga on bacillus dysentery, Babes on tetanus, etc., etc. Everyone who possesses the original series will want this volume as a compendium of the best data that have been accumulated since the beginning of its appearance and those who have not, will find it, in the main, an excellent statement of the progress of medicine during the past few years. One or two of the articles are almost too brief to be satisfactory, as that of Blandford on insanity, which touches only on the question of the autotoxic theory of Ford Robertson. There has been more progress even in this much abused subject that might have been noticed. The work is beautifully gotten up and elegantly illustrated.

A Reference Handbook of the Medical Sciences, Embracing the Entire Range of Scientific and Practical Medicine and Allied Science. By Various Writers. A New Edition, Completely Revised and Rewritten. Edited by Albert H. Buck, M.D., New York City. Volume V. Illustrated by Chromolithographs and 576 Half-tone and Wood Engravings. Cloth. Pp. 873. Price, $7.00. New York: Wm. Wood & Co. 1902.

This fifth volume of the new edition of Wood's Handbook is one of the best that has appeared. Besides a series of articles on subjects which form in themselves a very valuable composite text-book, it contains many other valuable monographs, such as that on the larynx by Makuen, on the liver by Musser, on the lymphatic system by Gage, on milk by Kober, and a vast number of others equally worthy of notice, but which, from their very number, prevent specification.

Association News.

ENTERTAINMENTS AT NEW ORLEANS.

Provisional List of Events Arranged by the Entertainment Committee.

From the "New Orleans Picayune" of April 1 we clip the following paragraphs:

Tuesday, May 5, in the evening, there will be a reception at the Palm Garden of the St. Charles Hotel which will cost about $1,000, exclusive of the music. The object is that the visiting physicians and ladies shall become acquainted with New Orleans people and that the ladies of the city shall assist in receiving. The reception will last from 5 to 7.

On Wednesday two large private receptions will be given, one an afternoon tea and one at night. On Thursday there will be a grand fête champêtre at the City Park, with music and refreshments, and on Friday there will be a boat ride on the river at which about 2,000 people will be entertained, and the ride will end at 6 p. m. and finish the social features of the convention.

There will be at the fête champêtre brilliant illuminations. Skiffs will be lighted with gay lanterns and flit about among the lakes, and the night will be made gaudy with color and pleasure.

Three or four physicians have promised receptions for various sections of the convention.

A trip to Cuba and fishing trips are contemplated.

Mrs. Samuel Delgado has been made chairman of a ladies' committee, and sixty or seventy-five ladies have been asked to serve on

the committee, which will undertake the general charge of the ladies who come with the physicians, at times when they are not at any entertainment given by the Entertainment Committee, and they will supervise entertainments, sightseeing, etc., in the mornings. Notices have been sent to these ladies, and as soon as a sufficient number of answers is received the committee will be called together to discuss plans.

It was reported that Dr. Rudolph Matas will have charge of a smoker for the Section on Surgery at the West End Hotel on Tuesday night. Dr. Dyer will have charge of the reception for the Section on Dermatology, and Dr. De Roaldes for the Section on Laryngology, and Dr. Henry Dickson Bruns that of the Section on Ophthalmology.

Dr. J. D. Bloom intends giving a yacht ride to special guests.

It was decided that all the smokers for the sections be referred to the Chairman, who will refer them to the physicians who will have charge, thus relieving the Banquet Committee, which will have charge of the arrangements of all banquets which sections or organizations desire to give.

Excursions.

The excursions, which are always such an enjoyable feature of the meeting, are briefly mentioned on page 1047 of this issue. Especial attention is called to the trip to San Antonio, because that city was a candidate last year for the privilege of entertaining the Association in 1903. Doubtless many will wish to take this trip through the oil and rice fields of Louisiana and Texas to the historic, quaint and beautiful city of San Antonio.

REGISTRATION OF MEMBERS.

The registration of members at the annual session is always a simple matter, to those who understand what is required.

Those registering come under one of three classes, 1, those who have already paid the annual dues for the current year; 2, those who have not paid the dues, and 3, those who join the Association at the session.

1. Those who have paid for the current year—and these have the least trouble—have been supplied with a small pocket card to take to the session, which is also a pocket certificate. To register one will fill out a registration card, found at the place of registration, and present this with his pocket card at the indicated window, where he will receive his badges, etc.

2. Those who have not paid their dues will fill out card as above and present it, with the annual dues, at the "Cash" window and receive their badges, etc. (Those who are behind in their dues must pay the back dues as well as those for the current year.)

3. Any one desiring to join the Association must have a certificate showing that the applicant is a member in good standing of an affiliated association in the state in which he resides. He will also fill out the registration card and present it, with his certificate and five dollars, at the window marked "New Members."

RAILROAD RATES.

SUMMARY OF THE TRANSPORTATION ARRANGEMENTS FROM ALL POINTS OF THE COUNTRY.

A résumé of the announcements that have been made from time to time in THE JOURNAL concerning transportation to New Orleans will show the following facts for the guidance of those who will attend the session: One fare for the round trip has been granted by the South Eastern, South Western and Central Passenger Associations, and also by roads covering a portion of the Western Passenger Association. This territory comprises Louisiana, Texas, Oklahoma, Indian Territory, Arkansas, Mississippi, Alabama, Florida, Georgia, South Carolina, North Carolina, Tennessee, Virginia, Kentucky, Missouri, Iowa, Minnesota, Wisconsin, Illinois, Indiana, Michigan, Ohio, and a portion of West Virginia, S. Dakota and Kansas.

From all western states not mentioned above, the regular summer excursion arrangements will prevail. From the eastern and New England states not mentioned, those who attend the session will have to pay a fare and a third rate in New England and the regular excursion rates through New York and Pennsylvania. This will take them to Washington or to Pittsburg or to Charleston, W. Va., or to such other point at which they will enter the Central or South Eastern Passenger Association territory. From these points on to New Orleans, half fare for the round trip will be the rate

As a further guide to indicate the railroad expenses, we give the following rates for the round trip from some principal cities of the United States:

Austin, Tex.	$17.80	St. Augustine, Fla.	$20.60
El Paso	31.90	Cincinnati	21.00
St. Paul	34.00	New York City	37.50
Minneapolis	34.00	Philadelphia	33.50
Chicago	23.00	Pittsburg	29 35
Omaha	29.50	Indianapolis	22.25
St. Louis	18.00	Nashville, Tenn.	16.75
Des Moines	27.85	Cleveland	28.25
Sioux Falls, S. D.	34.84	Baltimore	29.50
Buffalo	31.85	Washington	27.50
Boston	42.15	Louisville	19.00
Richmond, Va.	26.50	Evansville, Ind.	17.75

Extension of Limit of Ticket.

The regulations governing the round-trip-for-one-fare rate are as follows:

RATE.—One lowest regular first-class tariff (not temporarily reduced) fare to New Orleans and return.

DATES OF SALE.—Tickets to be sold on May 1-4, inclusive.

LIMIT OF TICKET.—Tickets to bear final limit of ten days from date of sale, except that by depositing tickets with joint agent not later than May 12, 1903, and on payment of fee of fifty cents at time of deposit, final limit may be extended up to and including May 30, 1903. Tickets to be limited for continuous passage in each direction, going trip to commence date of sale and return trip date of execution.

FORM OF TICKET.—Ironclad signature form of ticket to be used, providing for punch description of passenger going and return transit limits and execution by agent limit by depositing tickets with joint agent and payment of terminal line at New Orleans, also for extension of fee of fifty cents at time of deposit. Exchange orders must also require execution at New Orleans.

JOINT AGENCY.—The joint agency for deposit and extension of tickets will be located in Room 204, No. 204 Camp Street. The agency will be open from 8.00 a. m. to 8.00 p. m., and will be conducted in the name of Joseph Richardson, special agent. Tickets must be deposited personally by original purchaser. Tickets will be extended by means of an extension paster printed of perfect safety paper of the American Association of General Passenger and Ticket Agents, the signature of special agent, Mr. Richardson, being affixed by means of facsimile embossing stamp.

CONNECTING LINES.—The above rate and arrangement to be tendered to connecting lines for basing purposes. The sale of tickets or exchange orders to be so regulated as to require presentation at our gateways on the dates of sale authorized therefrom.

SPECIAL TRAINS.

LIST OF SPECIAL TRAINS FROM VARIOUS POINTS TO NEW ORLEANS.

CHICAGO.—The Chicago Medical Society is making arrangements with the Illinois Central to run a special train to New Orleans. The time of departure is expected to be about 12 o'clock noon, Sunday, May 3. The train will be a fully equipped and most comfortable one. Exact announcement will be made later. Those who find Chicago on their route to the session are invited to join this party. The train will also take on members from points along the line at which the train stops.

NEW YORK AND PHILADELPHIA.—A special train over the Southern Railway will leave New York City Saturday, May 2, at 4:25 p. m. and Philadelphia at 6:55 p. m. going to New Orleans, via Washington, Atlanta and Montgomery. The train will be composed exclusively of Pullman, dining, drawing room, sleeping, library and observation cars. Those desiring Pullman reservation should send in their names as soon as possible to Dr. F. H. Wiggin, 55 W. Thirty-sixth Street, New York City, or to agents of the Southern Railway.

Another train is planned over the New York and New Orleans Short Line. If enough do not reserve accommodation to warrant a special train, special cars will be used on a regular train, since many members have reserved berths. The majority of these will leave New York 3:25 p. m., Philadelphia 6:05 p. m. and Washington 10:01 p. m., May 2. The route is via Wash-

ington, Lynchburg, and Chattanooga. Further details and reservation of berths may be had from Eastern Passenger Agent L. J. Ellis, 398 Broadway, New York.

St. Louis.—A special train will leave St. Louis via the Illinois Central, Sunday, May 3, at 2:44 p. m. This train will be made up of sections from Chicago, Omaha, Des Moines and perhaps other points and will consist of Pullman palace cars, diners and the other equipments of comfortable travel. Further information and reservation of berths from St. Louis may be obtained from C. C. McCarty, 308 N. Broadway, St. Louis.

Omaha.—The delegation from Omaha may obtain further information from Dr. W. H. Brill, Omaha.

St. Joseph.—Those desiring to join the party from St. Joseph or vicinity should write Dr. Chas. Wood Fassett, St. Joseph, Mo.

Des Moines.—Arrangements, as mentioned above, have been made for the Iowa contingent to travel together over the Wabash, leaving Des Moines Saturday evening, May 2, arriving in St. Louis Sunday morning, where they will join the other delegations and spend the morning in St. Louis. Further details may be had of Dr. J. W. Cokenower, Des Moines.

Indianapolis.—The Hoosier special via the Big Four and Illinois Central railways will leave Indianapolis for New Orleans, by way of St. Louis, at 3:25 p. m., Sunday, May 3. This train will arrive at New Orleans early next morning. Requests for reservations of berths may be sent to Dr. J. F. Barnhill, 144 N. Penn Avenue, Indianapolis. A large delegation from Indianapolis is already made up.

Detroit.—A special train or else special cars on a regular train will run from Detroit to Cincinnati, where it will connect with the Q. and C. train mentioned in the next paragraph. Information may be had from Dr. A. P. Biddle, Detroit.

Cincinnati.—The Queen and Crescent Route will carry a special party from Cincinnati to New Orleans. We have been sent no details of the Detroit and Cincinnati excursions.

Kansas City.—A party is being made up of physicians from Kansas City, perhaps including Omaha, Lincoln, Sioux City and St Joseph physicians, who will have special cars attached to the Southeastern Limited of the 'Frisco system, leaving Kansas City Sunday, May 3, 6:30 p. m., via Memphis, 8 a. m. Monday, arriving in New Orleans Monday, May 4, at 7:40 p. m. Berths should be reserved early. Address Dr. J. V. Greene, 317 Rialto building, Kansas City, or reserve through agents of the 'Frisco System. The Omaha passenger agent is W. C. Melville, 205 S. 14th Street, Omaha. This route gives a daylight trip from Memphis to New Orleans.

Louisville—Special Pullman service has been arranged to New Orleans, via the Illinois Central Railroad from Louisville, Ky., and vicinity. Special arrangements have been made for connections between parties from Cincinnati, Evansville and Indianapolis (via the Big Four route), and the party from Louisville at Fulton, from thence proceeding as one train on the Illinois Central. The special party will leave Louisville at 12:55 p. m., May 4, arriving in New Orleans at 11 o'clock the next morning, but those who desire to reach New Orleans at an earlier date may do so, tickets being on sale from the last day of April at the reduced fare of one fare for the round trip. The advantages of making the trip in company with a congenial party are obvious, and it is hoped the delegates and members will join this party. Sleeper reservations can be made by addressing Dr. Henry Enos Tuley, 111 W. Kentucky Street, Louisville, Ky.

The New St. Charles Hotel.

WATER ROUTES TO NEW ORLEANS.

Atlantic Ocean Trip Details—No Mississippi River Arrangement.

The Southern Pacific line of passenger steamers (5,000 tonnage) between New York and New Orleans has made the rate of $50 round trip or $60 to go one way by rail and one way by water. Tickets will be good for three months, and this rate will apply to ships leaving New York April 18 and 25. The time in transit by water is about five days. The rates include room and board. The dates of return from New Orleans are May 6 and 13 at 9 a. m., and every seven days thereafter. This will be an opportunity for members to go by rail May 1 to 4, attend the meeting, take a trip to San Antonio, Texas, or some

other point and then sail for New York May 13. Further particulars may be had of L. H. Nutting, 349 Broadway, New York.

Another route to New Orleans, part land and part water route, is from Boston to Norfolk, Va., by steamer and thence to New Orleans by the Seaboard Air Line. The return will be by the same route. This round trip may be made for $41.75, including meals and stateroom while on steamer. Particulars may be had of C. L. Longsdorf, 360 Washington street, Boston.

The Mississippi River route plan has not materialized. Dr. Otho F. Ball, St. Louis, investigated the matter and reports that the effort to form an excursion on the river had to be abandoned because there seemed to be no direct line of boats in operation. A party may go from some other point, however, if arrangements can be made. We have received a number of requests for information about this route. It is not too early for houseboat parties to float down the river. This method would prove a delightful method of recreation.

BAGGAGE AND HOTELS.

ANNOUNCEMENTS OF NEW ORLEANS BUREAU OF INFORMATION AND OF HOTEL COMMITTEE.

For the convenience of those in attendance at the New Orleans Session the Bureau of Information has arranged with the Parcel Delivery and Express Company to handle baggage. Messengers of this company will be on special trains, but not on regular trains entering New Orleans. Members and others who arrive on the regular trains may, if they wish, keep their checks until their arrival at the Bureau of Information, Washington Artillery Hall, and have their baggage transfer orders made from that point. This company will charge 25 cents for each piece delivered anywhere in the city. The charge of the other principal companies of the city is 50 and 75 cents per piece.

Employment Bureau.

The Bureau of Information's arrangement with New Orleans-Crescent Information and Employment Bureau places the resources of that organization at the service of visitors to New Orleans. Trained clerks, stenographers, bookkeepers and office assistants of every description, they say, will be furnished, baggage insured, river excursions arranged, information given as to Louisiana or other resorts, hotels, etc., and accommodations reserved thereat. We suggest that those desiring stenographers, etc., by having the same engaged in advance, will secure the best service.

Hotels and Boarding Houses.

All the rooms at the St. Charles Hotel have been reserved already. The Committee on Hotels has 5,000 rooms available in other hotels and boarding houses. They recommend that those who wish accommodations write for them in advance, addressing Dr. E. D. Martin, 810 Common street, New Orleans, and stating what sort of accommodations are desired, whether with meals or bath, how far from the meeting places, etc.

SECTION BANQUETS.

ELABORATE PLANS.—ANNOUNCEMENTS.—MENTION OF MISCELLANEOUS MATTERS.

The Section on Diseases of Children will have no Section banquet at New Orleans.

Five or more stereopticons have been provided for the use of different Sections at New Orleans.

The Section on Cutaneous Medicine and Surgery will have a smoker in lieu of a banquet Tuesday, May 5, 1903.

The Fête Champêtre in the City Park, with the elaborate decorations and illuminations and music, will be a grand event.

The National Conference of State Medical Examiners and Licensing Boards will meet on the morning of May 4, at 9:30.

The officers of the Section on Ophthalmology announce a fine program of toasts at their Section banquet, Tuesday evening.

The courtesy of Messrs. Hansell, Tennisson and Belloeq and Dr. J. A. Storck in furnishing some of the illustrations of New Orleans and vicinity is acknowledged.

Special attention is being given by the New Orleans committee to the matter of a river excursion. Other smaller excursions on Lake Ponchartrain have been arranged.

Dr. F. H Wiggin, Secretary of the Judicial Council, desires us to announce that the Council will hold a meeting immediately after the adjournment of the first general meeting on Tuesday morning.

Unusual interest is being taken in special trains and in the arranging of parties to make the trip together. This is a delightful feature of each annual session, and members are this year planning to make the most of it.

The courtesies of the Boston Club and the Chess, Checkers and Whist Club have been extended to visiting members of the American Medical Association while in New Orleans. Membership badges will be all that is necessary to obtain admission.

The Section on Obstetrics and Diseases of Women will have a banquet Tuesday evening, to which members of the Association are invited. Plates will be $3. Those desiring to attend the banquet should notify the secretary, Dr. C. S. Bonifield, Cincinnati, as soon as convenient.

Prof. W. Uhthoff of Breslau, Germany, whose writings and work in ophthalmology are well known throughout the world, will be the guest of the Section on Ophthalmology. He is to take part in the work of the Section, and is expected to deliver a short address at the Section banquet.

The dedication of the Louisiana Purchase Exposition at St. Louis by President Roosevelt, April 30 to May 2, is conveniently on the path of many who go to New Orleans and affords an excuse for making St. Louis a rendezvous, from which the special trains should be well filled and a pleasant trip result.

The members of the Committee on Scientific Exhibit are making great efforts to have a creditable exhibit at this session. They announce that some features of the exhibit will be of especial interest and value to the general practitioner, while the specialists are taking much interest in their representations as well.

The officers of the Section on Laryngology and Otology desire that an announcement be made that anyone having anything to exhibit of special interest to laryngologists or to otologists, especially new instruments or apparatus, should communicate at once with the chairman, Dr. George L. Richards, Fall River, Mass., or with the secretary, Dr. J. F. Barnhill, Indianapolis.

The Chairman of the Section on Surgery announces his expectation of a very large attendance. Mikulicz of Breslau will be present and take part in the scientific work. Professor Krause of Berlin has been invited, but on last report it was feared he could not be present, owing to illness in his family, although it is probable that he may attend. Professor Moynihan of Leeds, England, is expected, but no final answer has at this time been received.

SCIENTIFIC EXHIBIT.

THE EXHIBIT OF PATHOLOGIC, PHYSIOLOGIC AND OTHER SPECIMENS AND APPARATUS.

The unavoidable delay incident to the organization of the Committee on Scientific Exhibit has been a serious drawback to the prosecution of the work. Many of those who contributed previously find it impossible this year owing to the limited time remaining. Remoteness of the place of meeting from sources of abundant material has also been urged as an excuse for not participating. There is, however, more than a saving remnant of those, recognizing the great practical value of the work, who are determined that the future of the movement shall not be jeopardized by any lapse at New Orleans. Such have come nobly to the rescue.

Although in the totals presented the showing may not equal that of the two previous meetings, the exhibit will be particularly interesting and instructive, because certain phases of pathology will be fully illuminated. An especial effort will be made to illustrate tropical diseases by means of gross anatomic as well as microscopic demonstrations. This will give to our southern colleagues an opportunity not so well afforded in the north. Such specialization is a natural evolution in the further conduct of the exhibit. Its scope and character will vary from year to year according to the place of meeting and the topics prominently considered in the sections. The committee has made strenuous endeavor to correlate the work of the exhibit with that of the Sections. Some of the officers have entered heartily into co-operation, with the result that we have been assured very complete groups of specimens illustrative of intestinal parasites, bacillary and amebic dysentery, malaria, yellow fever, surgical diseases of the kidney, ectopic pregnancy, fibroid tumors and other topics scheduled on the program.

It is hoped to have these groups demonstrated at stated hours indicated on the published program. In this way the exhibit will become educationally more efficient. The membership of the organization will thus be brought to realize that the exhibit belongs to the whole Association, and that it is not, as many are prone to suppose, merely an adjunct of the Section on Pathology and Physiology.

The local Committee of Arrangements has provided an ample hall for the exhibit, advantageously located and well lighted, in Washington Artillery Hall. Those who contemplate taking exhibits but have not yet made known the fact, should communicate at once with the chairman or nearest member of the committee.

Frank B. Wynn, Indianapolis, chairman; E. R. LeCount, Chicago; Harry T. Marshall, Baltimore; O. L. Pothier, New Orleans; Willard Bartlett, St. Louis, committee.

ASSOCIATION COMMITTEES.

The following list of committees and sub-committees and their officers and members is given here as of interest:

Committee on Award of Association Medal.—Lewis S. McMurtry, Louisville, Ky.; Burnside Foster, St. Paul; M. H. Fussell, Philadelphia.

Committee on Award of N. Senn Medal.—James H. Dunn, Minneapolis; M. L. Harris, Chicago; Floyd W. McRae, Atlanta, Ga.

Committee on Scientific Exhibit.—Frank B. Wynn, Indianapolis; E. R. LeCount, Chicago; Harry T. Marshall, Baltimore; O. L. Pothier, New Orleans; Willard Bartlett, St. Louis.

Committee on Scientific Research.—Alfred Stengel, Philadelphia; William Osler, Baltimore; L. Hektoen, Chicago.

Committee on Organization.—J. N. McCormack, Bowling Green; P. Maxwell Foshay, Cleveland, Ohio; George H. Simmons, Chicago.

Committee on Revision of Code of Ethics—E. Elliot Harris, New York; William H. Welch, Baltimore; T. J. Happel, Nashville, Tenn.; Nicholas Senn, Chicago, and Joseph D. Bryant, New York.

Committee on Reciprocity.—W. L. Rodman, Philadelphia; William H. Welch, Baltimore; Joseph M. Mathews, Louisville, Ky.; Henry Beates, Jr., Philadelphia, and T. J. Murray, Butte, Mont.

Committee on Public Health.—Charles O. Probst, Columbus, Ohio; J. N. Hurty, Indianapolis; W. H. Sanders, Mobile, Ala.; H. A. West, Galveston, Tex., and W. C. Gorgas, U. S. A.

Committee on Medical Education.—Arthur D. Bevan, Chicago; F. W. McRae, Atlanta, Ga.; Rudolph Matas, New Orleans; R. A. Marmion, U. S. N., and C. A. Daugherty, South Bend, Ind.

Committee on Prophylaxis of Syphilis.—Henry D. Holton, Brattleboro, Vt.; George M. Kober, Washington, D. C.; W. H. Sanders, Mobile, Ala.; Ludwig Weiss, New York, secretary; L. D. Bulkley, New York, and Louis E. Schmidt, Chicago.

Committee on Credentials and Registration.—George H. Simmons, Chicago; P. Maxwell Foshay, Cleveland, Ohio, and H. O. Walker, Detroit.

Notice to the Members of the House of Delegates.

The members of the House of Delegates are requested to meet in New Orleans, Monday, May 4, at 2 p. m. This meeting will be informal and no official business can be transacted.

Its purpose is to consider unofficially the business which must be transacted by the House of Delegates and to consider the result of the work of the several committees.

It is believed that this informal meeting on Monday will so fully acquaint the delegates of the work to be done that one meeting each morning will be sufficient to accomplish all the business of the Association. Thus the delegates will be free to attend the afternoon scientific work of the Sections.

FRANK BILLINGS, President.

PRELIMINARY PROGRAMS

Of the Sections of the American Medical Association, New Orleans Session, May 5-8, 1903.

The following lists of papers to be read in the various Sections are preliminary, and the order given is not necessarily to be followed in the official program. The official program will not be ready for distribution till the session.

Write to the secretary of the Section in reference to these programs, and not to THE JOURNAL.

Section on Practice of Medicine.

Chairman, W. S. Thayer, Baltimore; Secretary, James B. McElroy, Stovall, Miss.

Chairman's Address, W. S. Thayer, Baltimore.

The So-called Spotted Fever of the Rocky Mountains, Louis B. Wilson and William Chowning, Minneapolis.

Treatment of Vascular Tumors by the Injection of Boiling Water, John A. Wyeth, New York.

Further Experience with the Vertical Overlapping Method for the Radical Cure of Umbilical Hernia, Wm. J. Mayo, Rochester, Minn.

Evolution of the Mammalian Straight Gut, with Special Reference to Peritoneal Changes Incident to Rotation: Illustrated by Dissections and Mechanical Devices, W. T. Eckley, Chicago.

The Value of Enterostomy in Selected Cases of Peritonitis, Fred B. Lund, Boston.

Clinical Observations in Stomach Surgery, A. J. Oschner, Chicago.

Post-Operative Treatment of Gangrenous Appendicitis, Ernest Laplace, Philadelphia.

Dangers Attendant on Attempt at Gaining the Period of Interval in Operation for Appendicitis, Richard H. Gibbons, Scranton, Pa.

The Treatment of Fractures as Indicated by the Roentgen Rays, Carl Beck, New York.

Sunshine and Fresh Air versus Roentgen and Finsen Rays in the Treatment of Tuberculosis of Bones and Joints, De Forest Willard, Philadelphia.

Epithelioma Under the *X*-Ray; A Preliminary Report of the Histologic Changes, J. Clark Stewart, Minneapolis.

Contributions to the Therapy of Surgical and Other Diseases with X-Rays, Rudolph Matas, New Orleans.

The Surgical Treatment of Ascites due to Cirrhosis of the Liver, M. L. Harris, Chicago.

Varix of the Inferior Mesenteric Vein Complicated by Chronic Ulcerative Colitis; Operation, John E Summers, Jr., Omaha.

Congenital Dislocation of the Radius, Charles A. Powers, Denver.

Acute Epiphysitis of the Head of the Femur, Causing a Condition Subsequently Simulating Congenital Misplacement, John P. Lord, Omaha.

Necessity for more Care in the Treatment of Skull Fractures, W. H. Earles, Milwaukee, Wis.

Epispadias: Report of a Case Treated by a Modification of Caulwell's Operation, James B. Bullitt, Louisville, Ky.

Diverticulum of the Esophagus, A. E. Halstead, Chicago.

Cicatricial Ankylosis of the Jaws; a Contribution to Its Operative Treatment, Rudolph Matas, New Orleans.

Further Contribution to the Surgery of Undescended Testicle, Arthur Dean Bevan, Chicago.

Surgery of the Urinary Tract in the Female, Experimental and Clinical, J. B. Murphy, Chicago.

Consideration of Mammary Cysts in the Early Diagnosis of Breast Tumors, Robert Abbe, New York.

Tuberculosis of the Mammary Gland, A. H. Levings, Milwaukee, Wis.

The Closure of Wounds, Miles F. Porter, Fort Wayne, Ind.

Operative Treatment of Exophthalmic Goiter, T. C. Witherspoon, St. Louis.

Subcutaneous Injections of Paraffin for Deformities of the Nose, F. G. Connell, Leadville, Colo.

Abscess of the Spleen, Walter M. Spear, Rockland, Me.

Stricture of the Esophagus Following Typhoid Fever, Illustrated by Three Cases, James E. Thompson, Galveston, Texas.

A Case of Gas Bacillus Infection, Joseph Ransohoff, Cincinnati.

Section on Hygiene and Sanitary Science.

Chairman, H. M. Bracken, Minneapolis; Secretary, G. T. Swarts, Providence, R. I.

Address of Chairman.

Co-operation Methods for Improving the Usefulness of Statistical Classification of Causes of Death, Cressy L. Wilbur, Lansing, Mich.

Relation of Physicians to Correct Registration of Vital Statistics, W. A. King, Washington, D. C.

Present Status of the Filtration of Water, George W. Fuller, New York.

Drainage, Sewerage and Water Supply of New Orleans, Geo. G. Earl, New Orleans.

Leprosy from a Sanitary Standpoint, Isadore Dyer, New Orleans.

Tent Life in the Treatment of Pulmonary Tuberculosis, R. W. Craig, Phoenix, Ariz.

Where Under Our Form of Government Do Public Health Powers Reside and How Should They Be Exercised? W. H. Saunders, Montgomery, Ala.

The Future of Preventive Medicine, H. A. Moody, Mobile, Ala.

Thursday Morning and Afternoon, Joins Session with the Section on Practice of Medicine.

Discussion of the Manner of Infection and Prophylaxis of Typhoid Fever:

On the Source and Manner of Typhoid Fever, Wm. H. Welch, Baltimore.

Prophylaxis, John S. Fulton, Baltimore.

Discussion, John H. Musser, Philadelphia.

Discussion on the Manner of Infection and Prophylaxis of Yellow Fever:

Sources and Manner of Infection, James Carroll, U. S. A.

Prophylaxis, John Guiteras, Havana, Cuba.

Discussion, Stanford E. Chaille, New Orleans.

Discussion on the Manner of Infection and Prophylaxis of Plague:

Sources and Manner of Infection, W. J. Calvert, St. Louis.

Prophylaxis, Lewellys F. Barker, Chicago.

Discussion, F. G. Novy, Ann Arbor.

Section on Ophthalmology.

Chairman, John E. Weeks, New York; Secretary, Frank C. Todd, Minneapolis.

Address of the Chairman.

Vernal Conjunctivitis, Wm. Campbell Posey, Philadelphia.

Subtropical Trachoma, with Special Reference to a New Therapeutic Agent, Ruffin A. Wright, Mobile, Ala.

The Treatment of Trachoma, Edgar Doak Capps, Fort Worth, Texas.

The Action of Adrenalin in Acute Conjunctival Inflammation, Louis J. Lautenbach, Philadelphia.

Experimental Study on Some Methods of Combating Post-Operative Infection of the Anterior Segment of the Globe, E. C. Ellett, Memphis, Tenn.

Ocular Complications of Bright's Disease, Louis Stricker, Cincinnati.

Subconjunctival Medication with an Especial Reference to the Use of Salt-Sugar Solution in Acute Affections of the Anterior Portions of the Eye, Howard M. Morton, Minneapolis.

Albuminuric Retinitis and the Decapsulation of the Kidney, George F. Suker, Chicago.

SYMPOSIUM ON THE INFLUENCE OF THE CERVICAL SYMPATHETIC ON THE EYE.

(A) Experimental Researches Regarding the Influence of the Cervical Sympathetic on the Eye, Geo. E. de Schweinitz, Philadelphia.

(B) The Influence of Resection of the Superior Ganglion of the Cervical Sympathetic in Glaucoma, Wm. H. Wilder, Chicago.

(C) Influence of Resection of the Cervical Sympathetic in Optic Nerve Atrophy, Hydrophthalmus and Exophthalmic Goiter, James Moores Ball, St Louis.

(D) Pathology of the Cervical Sympathetic, John E. Weeks, New York.

Arteriosclerosis (Endarteritis) and Its Bearing on Retinal and Choroidal Lesions, Chas. Stedman Bull, New York.

Study of the Nerve Head in Relation to Certain Other Fundus Anomalies, Chas. H. Beard, Chicago.

Retinal Disease Limited to the Region of the Macula Lutea, Henry Gradle, Chicago.

Address: Congenital Total Color Blindness, Based on a Study of Nine Cases, Prof. Wm Uhthoff, Breslau, Germany.

Pathologic Exhibit, prepared by a committee consisting of Casey A. Wood, Chicago; Edward A. Shumway, Philadelphia, and H. V. Würdemann, Milwaukee, Wis.

Report of committee:

Methods of Preparing and Preserving Ophthalmic Specimens for the Museum. Address by Chairman, Casey A. Wood.

Some Points in the Pathology of the Eye. Illustrated by the Present Exhibit of Morbid Growths, Edward A. Shumway.

SYMPOSIUM ON THE BACTERIOLOGY OF THE EYE.

Bacteriologic Exhibit, prepared by a committee consisting of R. L. Randolph, Baltimore; Brown Pusey, Chicago; and Edgar Thompson, New York.

(1) The Bacteria Concerned in the Production of Eye Inflammations; address by Chairman, Robert L. Randolph.

(2) Bacteria in the Conjunctiva, Cornea, Iris, Ciliary Body and Choroid, and Changes Caused Thereby. (Illustrated by projection with a lantern of sections and lantern slides.) Brown Pusey, Chicago.

(3) The Essentials and Unessentials of Ophthalmic Asepsis, Harold Gifford, Omaha.

Development of the Fusion Center in the Treatment of Strabismus, Nelson M. Black, Milwaukee, Wis.

A Set of Charts for Stereoscope To Be Used for an Amblyopic Eye or for Treatment of Squint, Albert B. Hale, Chicago.

Cramp of the Ciliary Muscle Due to Eye-strain, J. W. Wright, Columbus, O.

Skiascopy as a Method of Precision, Edward Jackson, Denver.

Some Observations on the Eye Complications of Smallpox During the Recent Epidemic in Cleveland, A. R. Baker, Cleveland, O.

Some Rare Corneal Complications in Ophthalmia Neonatorum, A. A. Hubbell, Buffalo, N. Y.

Skin Grafting on the Eyelids, Oscar Dodd, Chicago.

Entropion and the Operations Employed for Its Relief, John O. McReynolds, Dallas, Texas.

Sympathetic Ophthalmia as the Result of Trauma in the Ciliary Region, John Sabert Mott, Kansas City, Mo.

A Case of Syphilitic Orbital Periostitis and Optic Neuritis, in which Vision Was Nearly Extinguished But Fully Restored, F. C. Hotz, Chicago

Traumatic Lesions of the Ocular Adnexa; with Report of a Case of Contused Wound of the Eyebrow Resulting in Complete Monocular Blindness Unaccompanied by Ophthalmoscopic Changes, Ellet O. Sisson, Keokuk, Iowa.

Exhibition of Specimens and New Instruments.

Extraction of the Crystalline Lens in High Myopia, H. V. Würdemann and Nelson M. Black, Milwaukee, Wis.

The Management of Myopia, J. H. Claiborne, Jr., New York.

Suggestions on the Pathogenesis of Glaucoma, N. J. Hepburn, New York.

Report of a Case of Complete Absence of Both Eyeballs at Birth, Lawrence R. Ryan, Galesburg, Ill.

Calcareous Degeneration of Corneal Cicatrices, H. Moulton, Fort Smith, Ark.

Ocular Incoördination and Cerebral Reflexes, F. Park Lewis, Buffalo, N. Y.

The Voluntary and Involuntary Brain Centers Controlling the Ocular Muscles, G. C. Savage, Nashville, Tenn.

Remarks on the Horopter, Geo. T. Stevens, New York.

Our Present Knowledge of the Cerebral Centers of the Eye, C. Barck, St. Louis.

Section on Diseases of Children.

Chairman, John C. Cook, Chicago; Secretary, Thos. S. Southworth, New York.

Address of Chairman.

Anatomic and Physiologic Correspondence of Child and Adult, William T. Eckley, Chicago.

The Treatment of Scarlet Fever; Its Complications and Sequelæ, H. M. McClanahan, Omaha.

Acute Fatty Degeneration, Probably Phosphorus Poisoning, in an Infant One Year Old, Isaac A. Abt, Chicago.

Hydronephrosis in a Child Four Years Old, with Operation and Recovery, S. W. Kelley, Cleveland, Ohio.

Acute Suppurative Cervical Adenitis of Infancy, Thos. S. Southworth, New York.

Rheumatism of the Appendix in Childhood, Frank X. Walls, Chicago.

Some Considerations in the Treatment of Broncho Pneumonia in Children, William Edgar Darnall, Atlantic City, N. J.

Belladonna in the Broncho-Pneumonias of Children, D. A. Hodghead, San Francisco.

Observations on Breast Feeding From an Obstetrician's Point of View, with Report of Cases, Effa V. Davis, Chicago.

Retained Intubation Tubes, with a Method of Treatment of the Larynx, Leading to Their Final Extraction, B. R. Shurly, Detroit.

The Infant Digestive Disturbances, A. C. Cotton, Chicago.

Observations on Prolonged Withdrawal of all Food in the Management of Certain Cases of Intestinal Disorders, Thomas D. Parks, Birmingham, Ala.

Infant Feeding; Its Relation to the Diarrheal Diseases of Infancy, J. G. Mastin, Chicago.

Case of Probable Gumma of the Liver in a Child of Six, J. P. Crozer Griffith, Philadelphia.

Every-day Problems in Infant Feeding, Henry Enos Tuley, Louisville, Ky.

The Special Value of Adrenalin in Acute Inflammations of the Mucous Membranes of Children, Louis J. Lautenbach, Philadelphia.

The Causes of High Mortality Among Infants in Institutions, with Considerations on Its Possible Reduction, Charles O'Donovan, Baltimore.

Otitis Media in Infancy, John Lovett Morse, Boston.

Capillary Bronchitis, Philip F. Barbour, Louisville, Ky.

Is the Study of Pediatrics Worth the Attention It Gets, and Does It Get the Attention It Deserves? C. F. Wahrer, Fort Madison, Iowa.

The Modern Treatment of Diphtheria, Louis Fischer, New York.

The Inherent Reaction of the Organism in the Diarrheas of Childhood, John Madison Taylor, Philadelphia.

Chorea, W. C. Hollopeter, Philadelphia.

Fresh Air in the Treatment of Children's Diseases, Robert W. Hastings, Boston.

Infant Feeding, Alex. McAlister, Camden, N. J.

Management of Catarrhal Pneumonia in Infants and Young Children, Charles G. Kerley, New York.

Grip in Children, William C. Williams, Chicago.

The Feeding of Healthy Infants, Charles Douglas, Detroit.

The Safranin Reaction in the Urine of Children, W. S. Christopher, Chicago.

Some Suggestions in the Therapy of Infancy, E. W. Saunders, St. Louis.

Aphthæ and Herpes Contracted by Children Drinking Milk from Cows Suffering from Foot and Mouth Diseases, E. F. Brush, Mount Vernon, N. Y.

Suggestions for Reducing the Prevalence of Summer Diarrhea, J. Ross Snyder, Birmingham, Ala

The Pathology of Summer Diarrheas of Children, G. W. Boot, Evanston, Ill.

Section on Stomatology.

Chairman, M. L. Rhein, New York; Secretary, Eugene S. Talbot, 103 State Street, Chicago.

Chairman's Address, M. L. Rhein, New York.

SYMPOSIUM ON DENTAL PULP.

Notes on Pulp Technic, Martha Anderson, Moline, Ill.

Minute Structures of the Dental Pulp, Vida A. Latham, Chicago.

The Vasomotor System, Eugene S. Talbot, Chicago.

The Dental Pulp Viewed Without the Microscope, T. E. Constant, Scarborough, York, England.

The Development of Hard Tissue in the Pulp, D. E. Causch, Brighton, England.

Some Histologic Facts Contradictory to the Theory of Odontoblasts, Michael Morganstein, Strassburg, Germany.

Pulp Hypertrophy of the Teeth, Oskar Romer, Strassburg, Germany.

Tolerance of Tissues for Foreign Bodies, with Special Reference to the Pulp and Peridental Membrane, M. H. Fletcher, Cincinnati.

Professional Responsibilities, A. E. Baldwin, Chicago.

The Dental Symptoms of Diabetes Mellitus, Hermann Prinz, St. Louis.

Germicides, A. H. Peck, Chicago.

A System for the Correction of Hare-lip and Cleft Palate, G. V. I. Brown, Milwaukee, Wis.

Is the Accomplishment of Reasonable Ideals in Dental Education Near at Hand, Chas. Chittenden, Madison, Wis.

The Influence of Local and General Disturbances on the Oral Secretions, Geo. F. Eames, Boston.

The Dentist in the U. S. Navy, Richard Grady, Baltimore.

Methods of Controlling Hemorrhage of the Oral Cavity, H. E. Belden, New Orleans.

Empyema of the Maxillary Sinus, O. N. Heise, Cincinnati.

Medical and Dental Libraries, Alice M. Steeves, Boston.

Orthodontic Facial Orthopedia, W. E. Walker, New Orleans.

A paper is also to be read by J. Choquet, Paris, France.

Section on Nervous and Mental Diseases.

Chairman, F. W. Langdon, Cincinnati; Secretary, F. Savary Pearce, 1407 Locust Street, Philadelphia.

Address of Chairman, F. W. Langdon, Cincinnati.

Some Graphic Observations on Ankle-Clonus, A. A. Eshner, Philadelphia.

Penetrating Wound of Both Cerebral Hemispheres, with Recovery, W. S. Lindsay, Topeka, Kan.

Trend of Modern Psychiatry and Its Relation to General Medicine, John Punton, Kansas City, Mo. Discussion opened by F. Savary Pearce, Philadelphia.

A Contribution to the Study of Visual Disturbances in Brain Injury, William E. Gamble, Chicago.

Epilepsy; A Clinical Study, J. G Biller, Cherokee, Iowa.

Pathology of Inebriety, T. D. Crothers, Hartford, Conn.

Ambulatory Automatism, Hugh T. Patrick, Chicago.

Relation of Epilepsy to Chronic Gastro-Intestinal Diseases, G. W. McCaskey, Fort Wayne, Ind.

The Use of the Ultra-Violet Ray in the Treatment of Functional and Organic Nervous Diseases, Albert E. Sterne, Indianapolis.

SYMPOSIUM ON RELATION OF PUBLIC SCHOOL METHODS TO PSYCHOSES.

Causes, Predisposing and Exciting, Herman H. Hoppe, Cincinnati.

Relation of the Public School to the Seminary and College as to Psychoses, F. Savary Pearce, Philadelphia.

Best Methods of Counteracting Psychoses Due to Strain and Stress, William J. Herdman, Ann Arbor, Mich.

Discussion to be opened by (1) H. N. Moyer, (2) John Punton, (3) F. W. Langdon.

Therapy of Insanity, Orpheus Everts, Cincinnati.

A Consideration of the Neuroses of Status Lymphaticus, A. P. Ohlmacher, Gallipolis, Ohio.

Some Unusual Cases of Paralysis Agitans, Philip Zenner, Cincinnati.

Report of Two Cases of Cerebral Hematoma, H. A. Tomlinson, St. Peter, Minn.

The Nervous Phenomena Associated with Movable Kidney, Wharton Sinkler, Philadelphia.

Relation Between Neurasthenia and General Paresis, E. D. Bondurant, Mobile, Ala.

Atrophy of Hand Muscles with Localized Sensory Disturbances; Possibly Early Syringomyelia, D. I. Wolfstein, Cincinnati.

Carcinoma of Spine and Meninges Secondary to Cancer of the Breast, F. Savary Pearce and A. C. Buckley, Philadelphia.

Ten Cases of Chronic Morphinism and Results of Treatment, A. J. Pressey, Cleveland, Ohio.

Some Toxemias in Relation to the Production of Nervous and Mental Disease, Samuel Bell, Detroit.

Treatment of Nervous and Mental Diseases of Toxic Origin, F. P. Norbury, Jacksonville, Ill.

Tabes in the Negro, D'Orsay Hecht, Chicago.

Treatment of Emotional Disturbances, Howell T. Pershing, Denver.

Climatology, etc., of the Insane, John W. Robertson, Alameda, Cal.

Section on Cutaneous Medicine and Surgery.

Chairman, John A. Fordyce, New York; Secretary, R. R. Campbell, 204 Dearborn Street, Chicago.

The Modern Conception of Eczema, John A. Fordyce, New York.

Larva Migrans, Henry W. Stelwagon, Philadelphia.

The Influence of the Menstrual Function on Certain Diseases of the Skin, L. Duncan Bulkley, New York.

Results in Radiotherapeutics and Clinical Conclusions, Dr. H. R. Varney, Detroit.

Fibroma Molluscum, Henry G. Anthony, Chicago.

Diagnosis of Cutaneous Syphilis, Isadore Dyer, New Orleans,

Treatment of Syphilis by Injections, M. L. Heidingsfeld, Cincinnati.

Syphilitic Fever, Eugene Carson Hay, Hot Springs, Ark.

Papilloma of the Sole, Douglass W. Montgomery, San Francisco.

Diagnosis of Smallpox, A. W. Brayton, Indianapolis.

Morbid Anatomy and Treatment of Smallpox, N. D. Brayton, Indianapolis.

Some Clinical Observations on Chickenpox, Jay F. Schamberg, Philadelphia.

Pityriasis Rosea, L. Weiss, New York.

Report of a Case of Pemphigus Chronicus, William Frick, Kansas City.

Tuberculosis Cutis Frambesioides, William S. Gottheil, New York.

Two Cases of Pemphigus Foliaceous, David Lieberthal, Chicago.

The Bacillus of Syphilis, Justin de Lisle, New York.

The Treatment of Leprosy, A. H. Ohmann-Dumesnil, St. Louis.

Atrophia Cutis Idiopathica; A Study of Two Cases, W. S. Gottheil, New York.

Notes on the Treatment of Lichen Planus, Joseph Zeisler, Chicago.

Clinical Results Obtained in the Use of Finsen's and Other Lights, L. E. Schmidt, Chicago.

Notes of An Interesting Case of Lupus Vulgaris, R. R. Campbell, Chicago.

The Consideration of Scarlet Fever, William L. Baum, Chicago.

Differential Diagnosis of Pemphigus and Dermatitis Herpetiformis, L. Blake Baldwin, Chicago.

Thursday morning, May 7, will be devoted to clinical demonstrations or rare skin diseases, with presentation of cases at Charity Hospital.

Section on Laryngology and Otology.

Chairman, Geo. L. Richards, Fall River Mass. Secretary, J. F. Barnhill, Indianapolis.

Address of Chairman.

Report of Cases Showing Instrument and Technic in the Cure of Deaf-Mutism, Maury M. Stapler, Macon, Ga.

The Treatment of Chronic Otitis Media, A. T. Mitchell, Vicksburg, Miss.

The Necessity of an Early Diagnosis and Treatment in Acute Suppurative Affections of the Middle-Ear, Frank D. Boyd, Fort Worth, Texas.

Nasal Polypus; Origin and Treatment, Chas. H. Baker, Bay City, Mich.

Diphtheria of the Nose, W. Scheppegrell, New Orleans.

Membranous Pharyngitis, John McReynolds, Dallas, Texas.

Report of a Case of Empyema of the Frontal Sinus, C. A. Thigpen, Montgomery, Ala.

Some Reasons for Past Unsatisfactory Results in the Treatment of Chronic Empyema of the Maxillary Sinus, Redmond Payne, San Francisco.

Malignant Diseases of the Nasal Passages, Francis J. Quinlan, New York.

Paraffin Injected Subcutaneously for the Correction of Nasal and Other Deformities, Harmon Smith, New York.

Paraffin in Nasal Deformities, P. J. H. Farrell, Chicago.

Some Observations on the Removal of Diseased Tonsils, Charles M. Robertson, Chicago.

(Note: Dr. Robertson will give a clinical demonstration of his method of removal of tonsils.)

The Special Influence of the High Altitude on the Nose and Throat, S. E. Solly, Colorado Springs.

A General Consideration of the Diseases of the Ethmoid Bones and Cells, Robert C. Myles, New York.

Non-Tubercular Hemorrhages of the Air-Passages, L. F. Page, Indianapolis.

The Resection Operation for the Correction of Deflections of the Nasal Septum, Otto T. Freer, Chicago.

How Far Should the Specialist in Rhinology and Otology Presume to Treat the Systemic Condition? C. M. Cobb, Lynn, Mass.

Non-Operable Catarrh, Fayette C. Ewing, St. Louis.

Exhibition of Author's Electro-Motor Nasal Saw, with Remarks, Melville Black, Denver.

Report of Three Cases: Case of Prolonged Intubation, Peculiar Symptoms Following Middle-Ear Operation and Case of Esophageal Obstruction Due to an Upper Alveolar Plate, Geo. F. Cott, Buffalo, N. Y.

The Early Manifestations of Laryngeal Tuberculosis: Their Recognition and Treatment, H. H. Briggs, Asheville, N. C.

The Teaching of Otology to the Undergraduate Medical Student, B. Alex. Randall, Philadelphia.

Auscultation of the Mastoid Process, A. H. Andrews, Chicago.

Proof of the Efficacy of Treatment by Aseptic Drainage in Acute Suppurative Otitis, H. Gradle, Chicago.

The Present Status of Ossiculectomy, J. A. Stucky, Lexington, Ky.

Treatment of the Eustachian Tube, Geo. B. McAuliffe, New York.

Some Recent Experiences with Chronic Suppurations of the Ear, Philip Hammond, Boston.

The Distribution of Blood Vessels in the Labyrinth of the Ear, with Exhibition of Preparation and Drawing, and (b) Wood's Metal Casts of the Middle-Ear with the Exhibition of Preparation and Lantern Demonstration, Geo. E. Shambaugh, Chicago.

Perisinusal Abscess of Lateral Sinus with Metastasis in Liver and Sterno-Clavicular Arthritis, Gordon King, New Orleans.

Otitis Media Catarrhalis Chronica, S. McCuen Smith, Philadelphia.

Mastoid Diseases and Meningitis, Seymour Oppenheimer, New York.

The Immediate Relief of Hysterical Manifestations in the Larynx by Suggestion, H. W. Loeb, St. Louis.

The Great Value of Drainage and Ice in the Early Stages of Mastoiditis, Sargent F. Snow, Syracuse, N. Y.

Deformity of the Nasal Septum in Atrophic Rhinitis: Shall We Operate? Kate W. Baldwin, Philadelphia.

Note: The pathologic and anatomic exhibit of specimens pertaining to the work of this Section, and new instruments will be continued Members are requested to bring with them any unusual or interesting specimens or instrument. An interesting collection is already promised.

J. F. BARNHILL, Secretary.

Section on Materia Medica, Pharmacy and Therapeutics.

Chairman, Solomon Solis-Cohen, Philadelphia; Secretary, C. S. N. Hallberg, 358 Dearborn Street, Chicago.

Address of Chairman.

Report of Committees on Papers presented at the last annual session:

On Dosage of Liquid Medicines, Frank Woodbury, H. C. Wood, Jr., and A. A. Eshner.

On Nerve Nostrums and Drug Addiction, A. W. Baer, W. J. Robinson and H. C. Wood, Jr.

Is Pharmacologic Action Determined by Chemical Structure or by Physical Characters? Arthur R. Cushney, Ann Arbor, Mich.

Research Problems of Pharmacology, Torald Sollmann, Cleveland, O.

The Physiologic Effects of the Ions, Ralph N. Webster, Chicago.

The Chemistry of Ergot, Albert B. Lyons, Detroit.

Mercury, Laura House Branson, Iowa City, Iowa.

The Absorption of Iron from the Alimentary Canal, Winfield S. Hall, Chicago.

Drugs Used in Nervous Diseases, George F. Butler, Alma, Mich.

The Mind as a Causative and Therapeutic Factor in Medicine, Bittle C. Keister, Roanoke, Va.

Limitations of the Dietetic Treatment of Diabetes, Arthur R. Elliott, Chicago.

Intestinal Antiseptics, Their Uses and Limitations, J. A. Storck, New Orleans, La.

Remedies for the Relief of Dropsy, Egbert LeFevre, New York, N. Y.

Demonstrated Pathologic Effects of Alcohol, T. D. Crothers, Hartford, Conn.

The Legitimate Therapeutic Uses of Alcohol, O. T. Osborne, New Haven, Conn.

The Management of Fever in General, Augustus A. Eshner, Philadelphia.

The Usefulness and Limitations of Drugs on Pyretic Conditions, Robert Reyburn, Washington, D. C.

The Therapeutic Value of Spinal Puncture for the Cerebral Symptoms of Typhoid Fever, J. H. Musser, Philadelphia.

The Limitations and Use of Aconite and Veratrum Viride, Warren B. Hill, Milwaukee, Wis.

Venesection: Its Use and Abuse, C. F. Wahrer, Fort Madison, Iowa.

Exercise as a Mode of Treatment of Heart Diseases, N. S. Davis, Jr., Chicago.

The Control of Hemorrhage by Drugs, with Particular Reference to Gelatin, Edward F. Wells, Chicago.

The Morphin Series, Smith Ely Jelliffe, New York.

The Composition of Some of the Lately Introduced Nostrums and So-called Synthetics, William J Robinson, New York.

The U. S. Pharmacopeia of 1900, Carl S. N. Hallberg, Chicago.

Advance in Electric Therapeutics, A. W. Baer, Chicago.

Recent Advances in Actinotherapy, William S. Gottheil, New York.

Dry Superheated Air in Therapeutics, Clarence E. Skinner, New Haven, Conn.

Section on Pathology and Physiology.

Chairman, Victor C. Vaughan, Ann Arbor, Mich.; Secretary, Joseph McFarland, 442 W. Stafford Street, Germantown, Pa.

The Chemistry of the Bacillus Coli Communis, Mary F. Leach.

The Chemistry of the Bacillus Typhosus, May Wheeler.

The Toxicity of the Intra-cellular Substance of Bacillus Typhosus, Louis M. Gelston.

The Anthrax Toxin, J. Walter Vaughan, St. Louis.

The Intra-cellular Toxin of Bacillus Pyocyaneus, Daniel McIntyre.

A Preliminary Chemical Study of the Hepatic Cells of the Ox, Frank Spencer and Frederick Munson.

The Toxicogenic Bacteria Found in Drinking Water, William G. Carhart.

The Chemical Tests for Morphin in the Presence of the Products of Bacterial Decomposition, Myron W. Clift.

Endothelioma of the Uterus, F. Robert Zeit, Chicago.

Condition of the Endometrium in Cases of Uterine Myomata, Thomas S. Cullen, Baltimore.

Demonstration of a "Mixed Tumor of the Kidney (Wilms), E. R. LeCount, Chicago

Multiple Periosteal Sarcomata of the Cranium, with Involvement of Retroperitoneal Lymph (Hemo-lymph) Nodes and Attending Severe Anemia, Walter L. Bierring, Iowa City, Iowa.

Primary Intestinal Tuberculosis, with Organism Pathogenic to a Calf, H. Gideon Wells, Chicago.

The Apparent Immunizing Value of Attenuated Tubercle Bacilli, E. A. de Schweinitz, Washington, D. C.

Studies of Antirennene, Joseph McFarland, Philadelphia.

A Case of Short-limbed Dwarfism, L. Hektoen, Chicago.

A Case of Giantism and Leontiasis Ossea, in the Lantern Slide Demonstration, E. R. LeCount for Peter Bassoe, Chicago.

Tissue Changes Under X-Ray Influence, W. S. Newcomet, Philadelphia.

The Protoplasmic Activity of the Renal Epithelium, as Determined by the Elimination of Pigments Injected Into the Circulation, W. S. Carter, Galveston, Texas.

Demonstration of New Physiologic Apparatus, Winfield S. Hall, Chicago.

The Working Capacity of a Muscle, J. G. Holmes, Chicago.

The Neuralgia and the Ependymal Epithelium of Teratoid Tumors, Henry A. Christian, Boston.

The Morphology and Biology of the Parasites of Blastomycetic Dermatitis, F. J. Otis and Newton Evans, Battle Creek, Mich.

The Principle of Invalid Feeding, L. Breisacher, Detroit.

The Biologic Aspects of Motion, Guido Bell, Indianapolis.

The Influence of Consanguinity on the Organs of Special Sense, L. W. Dean, Iowa City, Iowa.

The Cultivation of Trypanosoma Lewisii, F. G. Novy and W. J. McNeal, Ann Arbor, Mich.

A Study of the Influence of Blood Letting on Metabolism, also the Influence of Chinic Acid on Uric Acid Output, William Gies, New York.

Precision in the Determination of Human Parasites, Henry B. Ward, Lincoln, Neb.

Aerogenes Capsulatus Infection of the Neck, Louis Leroy, Nashville, Tenn.

New Members.

PROPOSED CODE OF ETHICS

Offered at Saratoga Springs, 1902, and to Be Acted on at New Orleans.

At the last session of the American Medical Association the following action was taken:

Dr. E. Eliot Harris, New York, presented the following resolution:

For more than a year some of the members of the Council of the New York State Medical Association have been engaged in a critical examination of the ethical part of the laws of the American Medical Association, resulting in the preparation of a revision of the Code of Medical Ethics. This revision has been approved by the Council of the New York State Medical Association, and the delegates have been instructed to present it to the House of Delegates at this session.

Resolved, That the President appoint a committee of five to examine and report for final action at the annual session in 1903 the proposed revised Code of Medical Ethics which is herewith submitted in writing;

Resolved, That the proposed revised Code of Medical Ethics be published in the Association's JOURNAL three times before the meeting in 1903.

On motion of Dr. C. A. L. Reed, Cincinnati, the resolution was adopted.

The following constitute the committee: Dr. E. Eliot Harris, New York, chairman; Dr. William H. Welch, Baltimore; Dr. T. J. Happel, Tennessee; Dr. Nicholas Senn, Chicago, and Dr. Joseph D. Bryant, New York.

CHAPTER I.—OF THE DUTIES OF PHYSICIANS TO THEIR PATIENTS AND OF THE OBLIGATIONS OF PATIENTS TO THEIR PHYSICIANS.

ARTICLE I.—DUTIES OF PHYSICIANS TO THEIR PATIENTS.

SECTION 1.—Physicians should not only be ever ready to obey the calls of the sick, but should be mindful of the high character of their mission and of the responsibility they must incur in the discharge of momentous duties. In their ministrations they should never forget that the ease, the health, and the lives of those entrusted to their care depend on skill, attention, and fidelity. In their deportment they should unite tenderness, cheerfulness and firmness, and thus inspire all sufferers with gratitude, respect and confidence. These observances are the more sacred because, generally, the only tribunal to adjudge penalties for carelessness or neglect is their own conscience.

SEC. 2.—Every case committed to the charge of a physician should be treated with attention and humanity, and reasonable indulgence should be granted to the caprices of the sick. Secrecy and delicacy should be strictly observed; and the familiar and confidential intercourse to which physicians are admitted, in their professional visits, should be guarded with the most scrupulous fidelity and honor.

SEC. 3.—The obligation of secrecy extends beyond the period of professional services; none of the privacies of individual or domestic life, no infirmity of disposition or flaw of character observed during medical attendance should ever be divulged by physicians, except when imperatively required to do so by the laws of the state. The force of the obligation of secrecy is so great that physicians have been protected in its observance by courts of justice.

SEC. 4.—Frequent visits to the sick are generally requisite, since they enable the physician to arrive at a more perfect knowledge of the disease, and to meet promptly every change which may occur. But unnecessary visits are to be avoided, as they give undue anxiety to the patient.

SEC. 5.—Ordinarily, the physician should not be forward to make gloomy prognostications, but should not fail, on proper occasions, to give to the friends of the patient timely notice of danger when it really exists; and even to the patient, if absolutely necessary. This notice, however, is often so peculiarly alarming when given by the physician, that its deliverance ought to be declined whenever it can be assigned to any other person of good judgment.

SEC. 6.—The physician should be the minister of hope and comfort to the sick, since life may be lengthened or shortened not only by the acts but by the words or manner of the physician whose solemn duty is to avoid all utterances and actions having a tendency to discourage and depress the patient.

SEC. 7.—The medical attendant ought not to abandon a patient because deemed incurable; for, continued attention may be highly useful to the sufferer, and comforting to the relatives, even in the last period of the fatal malady, by alleviating pain and by soothing mental anguish.

SEC. 8.—The opportunity which a physician has of promoting and strengthening the good resolutions of patients suffering under the consequences of vicious conduct ought never to be neglected. Good counsels, or even remonstrances, will give satisfaction, not offense, if they be tactfully proffered and evince a genuine love of virtue, accompanied by a sincere interest in the welfare of the person to whom they are addressed.

ARTICLE II.—OBLIGATIONS OF PATIENTS TO THEIR PHYSICIANS.

SECTION 1.—The members of the medical profession, on whom is enjoined the performance of so many important and arduous duties toward the community, and who are required to make so many sacrifices of comfort, ease, and health, for the welfare of those who avail themselves of their services, are surely entitled to the highest private and public recognition.

SEC. 2.—The first duty of a patient is to select as medical adviser one who has received a sound general and special education, whose habits are good, and who is not devoted to any pursuit incompatible with professional obligations.

SEC. 3.—The sick should always apply for advice in what may appear to be a trivial case, for the slightest accident may result gravely. It is also important that the patient seek assistance in the forming stage of a violent disease and communicate unreservedly to the physician its supposed cause.

SEC. 4.—The patient should be on friendly terms with the medical adviser and bear in mind that physicians are under the strongest obligations of secrecy.

SEC. 5.—Women should never allow feelings of delicacy to prevent their disclosing the seat of their peculiar complaints. However commendable a modest reserve may be in the common occurrences of life, its strict observance in medicine is often attended with serious consequences, and a patient may sink under a painful disease which might have been prevented had timely intimation been given to the physician.

SEC. 6.—The obedience of a patient to the directions of the physician should be prompt and implicit. Failure in one particular may render an otherwise judicious treatment dangerous and even fatal. This remark is equally applicable to the unauthorized renewal of prescriptions, and to diet, drink, raiment and exercise.

SEC. 7.—As patients become convalescent they are apt to suppose that the rules prescribed for them may be disregarded, and the consequence, but too often, is a relapse of the disease.

SEC. 8.—Patients should never allow themselves to be persuaded to take any medicine whatever that may be recommended to them by the self-constituted doctors who are so frequently met with and who pretend to possess infallible remedies for every disease. However simple some of their prescriptions may appear to be, it often happens that, besides being in themselves injurious, they are productive of much mischief by contravening the plan of treatment adopted by the physician in attendance.

SEC. 9.—Whenever possible, the patient should avoid even friendly visits of a physician who is not the regular attendant. But when such visits are received, there should be no conversation on the subject of the patient's disease, as a word may be spoken, without any intention of interference, which may destroy confidence in the course pursued and induce the patient to neglect the prescribed directions.

SEC. 10.—The patient or relatives should never send for a consulting physician without the express consent of the medical attendant.

SEC. 11.—Patients should, whenever practicable, send for their physicians in the morning, before the usual hour for going out, and this gives them the opportunity to so apportion their time as to prevent interference of engagements.

SEC. 12.—Except in emergencies patients should avoid calling on their medical advisers during the hours devoted to meals or sleep.

SEC. 13.—The sick should be always in readiness to receive the visits of the physician, as detention, even for a very short time, is often of serious import to some other sufferer.

CHAPTER II.—OF THE DUTIES OF PHYSICIANS TO EACH OTHER AND TO THE PROFESSION AT LARGE.

ARTICLE I.—DUTIES FOR THE SUPPORT OF PROFESSIONAL CHARACTER.

SECTION 1.—Every individual on entering the profession, and thereby becoming entitled to all its privileges and immunities, incurs an obligation to maintain its dignity and honor, to exalt its standing and to extend the bounds of its usefulness.

SEC. 2.—The physician should observe strictly such laws as are instituted for the government of the members of the profession; should honor the fraternity as a body; and, by unwearied diligence, should resort to every honorable means of enriching the science, and, at the same time, entertain a due respect for those seniors who, by their labors, have contributed to its advancement.

SEC. 3.—There is no profession from the members of which greater purity of character and a higher standard of moral excellence are required than the medical; and to attain such eminence is a duty every physician owes alike to the profession and to patients. It is due to these, as without it their respect and confidence can not be commanded; and to the profession because no scientific attainments can compensate for the want of correct moral principles.

SEC. 4.—It is incumbent on physicians to be temperate in all things, for the practice of medicine requires the unremitting exercise of a clear and vigorous understanding; and in emergencies—for which no physician should be unprepared—a steady hand, an acute eye, and an unclouded mind are essential to the welfare, and even to the life, of a human being.

SEC. 5.—It is derogatory to the dignity of the profession to resort to public advertisements or private cards inviting the attention of persons affected with particular diseases, offering advice and medicine gratis and promising radical cures; or to publish cases and operations in the daily prints, or to suffer such publications to be made; to invite laymen (other than relatives who may desire to be at hand) to be present at operations; to boast of cures and remedies; to adduce certificates of skill and success; or to employ any of the other methods of charlatans.

SEC. 6.—Equally derogatory to professional character it is for a physician to hold a patent for any surgical instrument or medicine; or to dispense, or promote the use of, a secret medicine, whether it be composed by this physician or the exclusive property of others, for if such nostrum be of real efficacy, any concealment regarding it is inconsistent with beneficence and professional liberality, and if mystery alone give it public notoriety, such craft implies either disgraceful ignorance or fraudulent avarice. It is highly reprehensible for physicians to give certificates attesting the efficacy of secret medicines, or of any of the other substances that may be used medicinally.

ARTICLE II.—PROFESSIONAL SERVICES OF PHYSICIANS TO EACH OTHER.

SECTION 1.—All practicing physicians and their immediate dependents are entitled to the gratuitous services of any one or more of the physicians residing near them.

SEC. 2.—Physicians afflicted with disease should not, as a general rule, undertake the treatment of their own sickness, nor of that of members of their family, for obvious reasons. In such circumstances they are peculiarly dependent on each other; therefore, kind offices and professional aid should always be cheerfully and gratuitously afforded. Visits ought not, however, to be obtruded officiously, as such civility may give rise to embarrassment or interfere with that choice on which confidence depends.

SEC. 3.—When a physician is summoned, from a distance, to the bedside of a colleague in easy financial circumstances, a compensation, proportionate to traveling expenses and to the pecuniary loss entailed by absence from the accustomed field of professional labor, should be made by the patient or relatives.

ARTICLE III.—OF THE DUTIES OF PHYSICIANS AS RESPECTS VICARIOUS OFFICES.

SECTION 1.—The affairs of life, the pursuit of health and the various accidents and contingencies to which a physician is peculiarly exposed sometimes require the temporary withdrawal of this physician from daily professional labor and the appointment of a colleague to act for a specified time.

SEC. 2.—The colleague's compliance is an act of courtesy which should always be performed with the utmost consideration for the interest and character of the family physician, and when exercised for a short period half of the pecuniary obligations for such services should be awarded to the acting physician.

ARTICLE IV.—OF THE DUTIES OF PHYSICIANS IN REGARD TO CONSULTATIONS.

SECTION 1.—The broadest dictates of humanity should be obeyed by physicians whenever and wherever their services are needed to meet emergencies occasioned by disease or accident.

SEC. 2.—The good of the patient being the sole object in view, any physician having a license to practice medicine conferred by a medical board authorized by the state may be aided in consultation.

SEC. 3.—No physician who indicates to the public that his practice is based on a sectarian system of medicine shall be entitled to professional fellowship or to recognition in medical bodies.

SEC. 4.—Consultations should be promoted in difficult cases, as they give rise to confidence and more enlarged views in practice.

SEC. 5.—The utmost punctuality should be observed in the visits of physicians when they are to hold consultations, and this is generally practicable, for society has been so considerate as to allow the plea of a professional engagement to take precedence over all others and to be a good reason for the relinquishment of any present occupation.

SEC. 6.—As professional engagements may sometimes interfere and delay one of the parties, the physician who first arrives should wait for a reasonable time, after which the consultation should be considered as postponed to a new appointment.

SEC. 7.—In consultations no rivalship or jealousy should be indulged; candor, probity and all due respect should be observed toward the physician in charge of the case.

SEC. 8.—The attending physician should be the first to question the sick, after which the consultant should have the opportunity to make such further inquiries as may be necessary.

SEC. 9.—After due examination of the patient, both physicians should retire to a private place for deliberation; and the one first in attendance should communicate the directions, agreed on, to the patient or friends, as well as any opinion which it may be thought proper to express.

SEC. 10.—No statement or discussion of the case should take place before the patient or friends, except in the presence of all the physicians attending, and by their common consent; and no opinions or prognostications should be delivered which are not the result of previous deliberation and concurrence.

SEC. 11.—The opinion of the physician in attendance should be delivered first to the patient or friends; and when there are several consultants they should deliver their opinions in the order in which they have been called.

SEC. 12.—No decision should restrain the attending physician from making such variations in the mode of treatment as any subsequent unexpected change in the character of the case may demand. But at the next consultation reasons for the variations should be stated. The same privilege, with its obligation, belongs to the consultant when sent for in an emergency during the absence of the family physician.

SEC. 13.—The attending physician, at any time, may prescribe for the patient; not so the consultant, when alone, except in a case of emergency or when called from a considerable distance. In case of emergency the consultant should do what is needed, and in the other case should do no more than make an examination of the patient and leave a written opinion, under seal, to be delivered to the attending physician.

SEC. 14.—In consultations theoretical discussions should be avoided, as occasioning perplexity and loss of time. For there may be much diversity of opinion concerning speculative points, with perfect agreement in those modes of practice which are founded not on hypothesis, but on experience and observation.

SEC. 15.—All discussions in consultation should be held as confidential. Neither by words nor manner should any of the parties to a consultation assert or intimate that any part of the treatment pursued did not receive his assent.

SEC. 16.—Should an irreconcilable diversity of opinion occur when several physicians are called on in consultation, the opinion of the majority should be considered as decisive; but if the numbers be equal on each side, then the decision should rest with the attending physician.

SEC. 17.—It may happen that two physicians can not agree in their views of the nature of a case and of the treatment to be pursued. In the event of such disagreement a third physician should, if practicable, be called in and, if circumstances prevent the adoption of this course, the patient or friends should make the selection. The physician so designated should take charge of the case and the other should then gracefully retire from any further deliberation in the consultation, or participation in the management of the case.

SEC. 18.—As circumstances sometimes arise to render a special consultation desirable, when the continued attendance of two physicians might be objectionable to the patient, the physician whose

assistance is required in such cases should sedulously guard against all future, unsolicited attendance. Such consultations requiring an extraordinary portion of time and attention, at least a double fee should be expected.

Sec. 19.—A physician who is called in consultation should observe the most honorable and scrupulous regard for the character and standing of the attending physician, whose conduct of the case should be justified as far as can be, consistently with a conscientious regard for truth, and no hint or insinuation should be thrown out which could impair the confidence reposed in the attending physician.

ARTICLE V.—DUTIES OF PHYSICIANS IN CASES OF INTERFERENCE.

Section 1.—Medicine being a liberal profession, those admitted to its ranks should found their expectations of practice entirely on the extent of their medical education.

Sec. 2.—The physician, in his intercourse with a patient under the care of another physician, should observe the strictest caution and reserve; should give no disingenuous hints relative to the nature and treatment of the patient's disorder, nor should the course of conduct of this physician directly or indirectly tend to diminish the trust reposed in the attending physician.

Sec. 3.—The same circumspection should be observed when, from motives of business or friendship, a physician is prompted to visit a person who is under the direction of another physician. Indeed, such visits should be avoided, except under peculiar circumstances; and when they are made, no particular inquiries should be instituted relative to the nature of the disease, or the remedies employed, but the topics of conversation should be as foreign to the case as circumstances will admit.

Sec. 4.—A physician ought not to take charge of, or prescribe for, a patient who has recently been under the care of another physician in the same illness, except in case of a sudden emergency, or in consultation with the physician previously in attendance, or when that physician has relinquished the case or has been dismissed in due form.

Sec. 5.—Placed in the position stated in the preceding section, the physician should never throw out damaging insinuations on the practice previously adopted, and, indeed, should justify it if consistent with truth and probity; for it often happens that patients become dissatisfied when they are not immediately relieved, and, as many diseases are naturally protracted, the seeming want of success, in the first stage of treatment, affords no evidence of a lack of knowledge or skill.

Sec. 6.—When a physician is called to an urgent case, because the family attendant is not at hand, unless assistance in consultation is desired, this physician should resign the care of the patient immediately on the arrival of the family physician.

Sec. 7.—It often happens, in cases of sudden illness, or of accidents and injuries, owing to the alarm and anxiety of friends, that several physicians are simultaneously summoned. Under these circumstances, courtesy should assign the patient to the first who arrives and who, if necessary, may invoke the aid of some of those present. In such a case, however, the acting physician should cause the family physician to be called, and should withdraw unless requested to continue in attendance.

Sec. 8.—Whenever a physician is called to the patient of another physician during the enforced absence of that physician the case should be surrendered on the return of the absentee.

Sec. 9.—A physician, while visiting a sick person in the country, may be asked to see another physician's patient in consequence of a sudden aggravation of the disease. On such an occasion the immediate needs of the patient should be attended to and the case relinquished on the arrival of the attending physician.

Sec. 10.—When a physician who has been engaged to attend an obstetric case is absent and another is sent for, delivery being accomplished during the vicarious attendance, the acting physician is entitled to half the fee, but must resign the patient on the arrival of the physician first engaged.

ARTICLE VI.—OF DIFFERENCES BETWEEN PHYSICIANS.

Section 1.—Diversity of opinion and opposition of interest may, in the medical as in other professions, sometimes occasion controversy and even contention. Whenever such cases unfortunately occur and can not be immediately terminated, they should be referred to the arbitration of a sufficient number of physicians or a court-medical.

Sec. 2.—A peculiar reserve must be maintained by physicians toward the public in regard to some professional questions, and as there exist many points in medical ethics and etiquette through which the feelings of physicians may be painfully assailed in their intercourse, and which can not be understood or appreciated by general society, neither the subject-matter of their differences nor the adjudication of the arbitrators should be made public.

ARTICLE VII.—OF PECUNIARY ACKNOWLEDGMENT.

Section 1.—There is no profession by the members of which eleemosynary services are more liberally dispensed than the medical, but justice requires that some limits should be placed to their performance.

Sec. 2.—Poverty, mutual professional obligations, and certain of the public duties named in Sections 1 and 2 of Article 1, of Chapter III, should always be recognized as presenting valid claims for gratuitous services; but neither institutions endowed by the public or by the rich, or by societies for mutual benefit, for life insurance, or for analogous purposes, or any profession or occupation, can be admitted to possess such privilege.

Sec. 3.—It can not be justly expected of physicians to furnish certificates of inability to serve on juries, or to perform militia duty; or to testify to the state of health of persons wishing to insure their lives, obtain pensions, or the like, without a pecuniary acknowledgment. But to persons in indigent circumstances such services should always be cheerfully and freely accorded.

Sec. 4.—Some general rules should be adopted by the physicians in every town or district relative to the minimum pecuniary acknowledgment from their patients; and it should be deemed a point of honor to adhere to these rules with as much uniformity as varying circumstances will admit.

Sec. 5.—It is derogatory to professional character for physicians to pay or to offer to pay commissions to any person whatsoever who may recommend to them patients requiring general or special treatment or surgical operations. It is equally derogatory to professional character for physicians to demand or to receive such commissions.

CHAPTER III.—OF THE DUTIES OF THE PROFESSION TO THE PUBLIC AND OF THE OBLIGATIONS OF THE PUBLIC TO THE PROFESSION.

ARTICLE I.—DUTIES OF THE PROFESSION TO THE PUBLIC.

Section 1.—As good citizens it is the duty of physicians to be very vigilant for the welfare of the community, and to bear their part in sustaining its institutions and burdens; they should also be ever ready to give counsel to the public in relation to subjects especially appertaining to their profession, as on questions of sanitary police, public hygiene and legal medicine.

Sec. 2.—It is the province of physicians to enlighten the public in regard to quarantine regulations; to the location, arrangement, and dietaries of hospitals, asylums, schools, prisons and similar institutions; in relation to the sanitary police of towns, as drainage, ventilation, etc.; and in regard to measures for the prevention of epidemic and contagious diseases; and when pestilence prevails, it is their duty to face the danger, and to continue their labors for the alleviation of the suffering people, even at the risk of their own lives.

Sec. 3.—Physicians, when called on by legally constituted authorities, should always be ready to enlighten inquests and courts of justice on subjects, strictly medical, such as involve questions relating to sanity, legitimacy, murder by poison or other violent means, and various other subjects embraced in the science of medical jurisprudence. It is but just, however, for them to expect due compensation for their services.

Sec. 4.—It is the duty of physicians, who are frequent witnesses of the great wrongs committed by charlatans, and of the injury to health and even destruction of life caused by the use of their treatment, to enlighten the public on these subjects, and to make known the injuries sustained by the unwary from the devices and pretensions of these artful impostors.

Sec. 5.—Physicians ought to use all the influence which they possess to discourage pharmacists from vending the secret or other medicines of charlatans, or from being in any way engaged in their manufacture.

ARTICLE II.—OBLIGATIONS OF THE PUBLIC TO PHYSICIANS.

Section 1.—The benefits accruing to the public, directly and indirectly, from the unwearied labors of the profession, are so numerous and important that physicians are entitled to the utmost consideration and respect from the community.

Sec. 2.—The public ought to entertain a just appreciation of medical qualifications, to make a proper discrimination between true science and the assumptions of ignorance and charlatanism; and to afford every encouragement and facility for the acquisition of thorough medical education.

Medical Organization.

The Reorganized States.

It is now less than a year since any of the states adopted the plan of organization, but the progress made in each of them even in that short time has been so marked as to be worthy of special mention.

Michigan.

Michigan accepted the new plan in June, 1902, with only such changes as were necessary to adapt it to local conditions. Dr. Connor informs me that at that time they had but 10 recognized societies, only 5 of which were active, 7 medical clubs, and 5 district societies. The total membership in the state society was 610, of whom 100 were so in arrears for dues that they were practically out.

Much enthusiasm was manifested from the outset and, under the able leadership of Drs. Connor, Bulson, Haughey, Biddle and others too numerous to mention, 70 counties, out of 83 in the state, have been organized and chartered, and missionary work is being actively pressed in each of the others. The paid-up membership has been increased in ten months to over 1,600, and is expected to reach 2,000 before the annual meeting, new members being reported daily. Prominent members from all over the state write that the hopes, aspirations and good fellowship have increased even more than the membership.

Michigan has gone farther than any other state in making its council a strong executive body, with full authority to act for the society in the interim of meetings. The results achieved, as well as those in process of fulfillment, clearly demonstrate the wisdom of this policy. The council held frequent meetings and soon had the state divided into districts, with an active councilor in each who called the physicians together in county after county, brought to their attention the evils which have resulted to both the profession and the public from dissensions in its own ranks in the past, and the good which must result to all from such harmony and co-operation, which can only be brought about by local organizations. These

efforts have been well supported by the journal of the state society, which was established by the council as soon as possible after the re-organization, is the property of the society, is sent free to every member in lieu of the volume of transactions, and is already on a paying basis.

Tennessee.

The Tennessee State Society adopted the Association plan, practically without change, in May, 1902. At that time 14 county societies existed, some active, some more or less dormant, and the total membership in the state body was about 280. During the ten months 49 county societies have been organized and chartered and the membership in the state body has been increased to over 800, with promise of five or six more counties, and a total membership of over 1,000 before the next annual meeting. Drs Miller, Savage, McSwain, Happel, Roberts and many others have been untiring in their efforts to bring about these results, and a revival of interest in professional affairs is manifest in almost every section.

Kentucky.

Kentucky was the second state to adopt the Association plan without change. Twenty county societies then existed, several of them dormant. The total membership in the state association was 551, and about 25 per cent. of these were in arrears for dues. In ten months 72 county societies had been organized and chartered, and 20 more have appointments for organization. Reports from county secretaries are not yet due, and the total membership can not be known accurately until these come in, but it is believed it will be increased to over 1,500 paid-up members. The president of the state association has visited and organized every county in his large district not already in line, as have Drs. Shirley and Wells in their respective districts. Other councilors especially active have been Drs. Frank, Sory, A. T. McCormack, and Steele Bailey, who is also secretary of the association.

OTHER STATES.

Data in regard to Ohio, Colorado and Arkansas, could not be obtained in time for this issue, but active, systematic work is being done in these states, of which full details will be supplied later.

Pennsylvania and Connecticut were previously organized on lines similar to those of the Association plan, and excellent work is going on in these states. It is believed, however, that they would be especially benefited by incorporating the essential features of the uniform system.

Several other states reorganized last year and thought they were adopting the plans of the Association, but in practice it was found that they had modified it almost beyond recognition. So much trouble and confusion has resulted in these states that most of them will probably substitute the uniform system at their coming annual meetings. In the future it will doubtless be better for the friends of a systematic organization of the profession to advise that existing constitutions and by-laws be retained, rather than go through a form of reorganization in which the essential features of the Association plan are ignored. There are sparsely settled districts in nearly every state in which the rank and file of the profession has never been reached in the past, and this has been and will continue to be a difficult problem, but the uniform system proposed is susceptible of infinite and easy modifications as experience may develop the necessity for them, and the results in the states first named above show that it meets the conditions more fully than any other plan which has yet been tried.

This whole question is so important that it is earnestly suggested that representatives to the House of Delegates at the next session come to New Orleans with the facts and figures in regard to all these matters in their respective states well in hand, and that one or more days be given to the consideration of the subject.

J. N. McCORMACK.

Bowling Green, Ky.

Omaha-Douglas County (Neb.) Medical Association.

At its meeting, March 27, the new constitution suggested by the American Medical Association for county organizations was formally adopted. The reorganized society has a membership of 114 out of a possible 125 eligible physicians in the county.

Iosco County (Mich.) Medical Society.

The physicians of this county met at East Tawas, March 25, and organized this society as a branch of the Michigan State Medical Society, with the following officers: Dr. Henry A. Goodale, East Tawas, president; Dr. George S. Darling, Tawas City, vice president, and Dr. Frederick C. Thompson, East Tawas, secretary.

Marinette County (Wis.) Medical Society.

Pursuant to a call from Theodore J. Redelings, eleven physicians met at Marinette, March 24, and organized a county society on the lines proposed by the American Medical Association. Dr. Theodore J. Redelings, Marinette, was elected president; Dr. William Sellars, Wausaukee, vice-president, and Dr. A. T. Nadeau, secretary and treasurer.

Medical Society of the Tenth Councilor District of Arkansas.

The Northeast Arkansas Medical Society met at Fort Smith, March 24 and 25, and reorganized as the Medical Society of the Tenth Councilor District of Arkansas. Dr. E. G. McCormick, Prairie Grove, was elected president; Dr. John S. Shibley, Paris, vice-president; Dr. Frank B. Young, Springdale, secretary, and Dr. Buchanan Hatchett, Fort Smith, treasurer. A strong representation from every county in the district was present, and the society starts with the most flattering prospects for its future. This is the first councilor district medical society organized in Arkansas. It is to meet semi-annually, in March and September. The next meeting will be held in Fayetteville, September 29 and 30.

Denver Academy of Medicine.

After a year's preliminary work and agitation carried on by a few prominent members of the profession, the organization of the Denver Academy of Medicine was consummated Tuesday, March 31, 1903. The object of the academy, as expressed in its constitution is "the promotion of the science and art of medicine, co-operation among local medical organizations, the maintenance of a place for medical gatherings and the support of medical libraries." It is expected that in the near future the medical profession of Denver will possess a home of their own, where the various medical libraries and collections now scattered will be united under one roof, where all the medical societies of the city will meet, and a museum and laboratory for investigation and research will be maintained. The election of officers resulted as follows: President, Dr. Henry Sewall; vice-president, Dr. George B. Packard; trustees, 3 years, Drs. W. A. Jayne and W. W. Grant; 2 years, Drs. Thomas H. Hawkins and L. E. Lemen; 1 year, Drs. W. H. McLauthlin and I. B. Perkins; secretary, Dr. C. K. Fleming; treasurer, Dr. Frank E. Waxham; librarian, Dr. C. D. Spivak.

Kentucky County Societies.

The work of organization progresses in Kentucky, as is shown by the following record:

The physicians of Bailey County organized at Middlesboro, March 23, electing Dr. Leslie L. Robertson, president, and Dr. Macauley Arthur, secretary, both of Middlesboro.

The physicians of Taylor County met at Campbellsville, March 25, and after an address by Dr. Robert C. McChord, Lebanon, councilor of the district, organized a county society. Dr. Jefferson L. Atkinson and James B. Buchanan, both of Campbellsville, were elected respectively president and secretary.

The physicians of Knox County met at Barbourville, March 23, and after an address by Dr. Steele Bailey, Stanford, secretary of the Kentucky State Medical Society, organized a county society. Dr. Benjamin F. Herndon was elected president, and Dr. Granville H. Albright, secretary, both of Barbourville. This society promises to have every physician in the county enrolled in its paid-up membership before the meeting of the state society.

The physicians of Pendleton County met at Falmouth, March 31. After an address by Dr. J. E. Wells, councilor for that

district, a society was organized with Dr. J. H. Barbour, Falmouth, president, and Dr. John E. Wilson, Falmouth, secretary. The constitution proposed by the American Medical Association was adopted without change, and it was promised that every physician in the county would be enrolled in the membership before the next meeting.

The physicians of Simpson County met at Franklin, March 30, and after a talk by Dr. J. N. McCormack, Bowling Green, organized a county society, which promises soon to enroll in its membership every physician in the county. Dr. George W. Duncan, Franklin, was elected president; Dr. Morton M. Moss, Franklin, secretary, and Dr. James C. Douglass, delegate to the state association.

The physicians of Spencer County met at Taylorsville, March 26, and after listening to a talk by Dr. J. N. McCormack, Bowling Green, organized a county society, electing Dr. Henry C. Mathias, president, and Dr Wiley Rogers secretary, both of Taylorsville. All but three of the physicians in the county were present.

Societies.

COMING MEETINGS.

AMERICAN MEDICAL ASSOCIATION, FIFTY-FOURTH ANNUAL MEETING, NEW ORLEANS, MAY 5-8.

Tennessee State Medical Society, Nashville, April 14-16.
Medical Association of Georgia, Columbus, April 15.
South Carolina Medical Association, Sumter, April 15-16.
Iowa State Medical Society, Sioux City, April 15-17.
Mississippi State Medical Association, Vicksburg, April 15 17.
Medical Association of the State of Alabama, Talladega, April 21.
Medical Society of the State of California, Santa Barbara, April 21.
Medical Association of the State of Missouri, Excelsior Springs, April 21-23.
Kentucky State Medical Society, Louisville, April 22-24, 1903.
Texas State Medical Association, San Antonio, April 28.
Louisiana State Medical Society, New Orleans, April 28-30.
Medical and Chirurgical Faculty of Maryland, Baltimore, April 28-30.
Nebraska State Medical Society, Lincoln, April 28-30.
Illinois State Medical Society, Chicago, April 29-May 2.
Arkansas Medical Society, Jonesboro, April 30-May 2.
Association of American Medical Colleges, New Orleans, May 4.
American Proctologic Society, New Orleans, May 5.
Kansas Medical Society, Concordia, May 6-9.
American Academy of Medicine, Washington, D. C., May 11-12.
American Therapeutic Society, Washington, D. C., May 11-13.
Oklahoma Territorial Medical Association, Guthrie, May 12.
American Association of Genito-Urinary Surgeons, Washington, D. C., May 12-14.
American Surgical Association, Washington, D. C., May 12-14.
American Orthopedic Association, Washington, D. C., May 12-14.
American Pediatric Society, Washington, D. C., May 12-14.
Association of American Physicians, Washington, D. C., May 12-14.
American Medico-Psychological Association, Washington, D. C., May 12-15.
American Ophthalmological Association, Washington, D. C., May 13-14.

Iowa State Medical Society.—The annual meeting will be held in Sioux City, April 15 to 17. At this meeting the adoption of the constitution suggested by the American Medical Association for state societies will be an important order of business.

Comanche County (Texas) Medical Society.—At the regular meeting held in De Leon, March 14, Dr. T. P. Weaver, De Leon, was elected president; Dr. Leven B. Thomas, Comanche, vice-president, and Dr. John D. Moorhead, De Leon, secretary and treasurer.

Breckenridge County (Ky.) Medical Society.—Physicians of Breckenridge County met at Hardinsburg, March 18, and effected a reorganization of the society, electing Dr. Robert T. Dempster, Glendeane, president, and Dr. Milton Board, Jr., Hardinsburg, secretary.

Westchester County (N. Y.) Medical Association.—At the annual meeting held at White Plains, March 26, Dr. Thomas J. Acker, Croton-on-Hudson, was elected president; Dr. William D. Granger, Bronxville, vice-president, and Dr. Donald T. McPhail, Purdy Station, secretary and treasurer.

Shawnee (Okla.) Physicians' Club.—About 20 physicians of Shawnee met, March 26, and organized a medical society whose principal object is the building of a hospital in the city. Dr. John A. Walker was elected president; Dr. Hugh Goodwin, vice-president, and Dr. A. T. Grayson, secretary and treasurer.

Woman's Medical School Alumnae Association.—The twenty-third annual meeting of the alumnæ of Woman's Medical School (Northwestern University) will be held April 29 in Chicago. The meeting has been so arranged as to allow the members to attend the meetings of the Illinois State Medical Society and the American Medical Association.

CHICAGO MEDICAL SOCIETY.

Regular Meeting, held March 25, 1903.

The President, Dr. William A. Evans, in the Chair.

Pneumococcus Septicemia.

Dr. J. L. Miller said that bacteriemia was a more suitable term than septicemia. Whether an infection remains localized or becomes generalized depends largely on the resistance of the individual and the virulence of the infectious agent. The *Diplococcus pneumoniæ* inoculated into a highly susceptible animal, as the mouse and rabbit, does not manifest itself as a localized process, but becomes a bacteriemia. In less susceptible animals, when inoculation is made directly into the lung, a process resembling pneumonia follows. Pathologic findings, animal inoculations and clinical observations indicate that pneumonia is often a septicemia before blood cultures actually demonstrate the organism. Two investigators report positive cultures from the blood in all cases examined; 154 cases collected from other reports show positive results in 24 per cent. The earliest positive results were obtained on the second day of the disease. Blood cultures will be of little diagnostic aid, as the disease is easily recognized from the physical findings. From a prognostic standpoint it is of value, a bacteriemia indicating a grave infection. Eighty-seven per cent. positive cases died, and only 22 per cent. of the negative cases.

The Diagnosis of Pneumonia.

Dr. Arthur R. Edwards read this paper. He said that mistakes are rare in the diagnosis of primary frank pneumonia in adults. They occur mostly in the aged, alcoholics, children, and in pneumonia secondary to cancer, nephritis, diabetes, etc. Therefore, the physician should watch all diseases when the respiration, pulse and temperature rise, or when, even without these or other symptoms, the subject of chronic disease is not doing well The onset symptoms, the chill in adults, convulsions in children, vomiting in the very young or in adolescents, suggest at least the possible onset of lobar pneumonia. Chill, pain in the side, sudden high fever and rusty sputum are almost positively final, since pneumonia is practically the only disease where they occur, guarding against the chief diagnostic confusion, infarct of the lung, in which the same symptoms may obtain, although here the sputum is reddish, but is not viscid, and is usually far more abundant than in pneumonia.

As to diagnosis from the physical findings in the lungs, these findings are usually detected in the frank case of pneumonia on a thorough thoracic examination, and, as a rule, appear within two days after the characteristic symptoms of onset. These physical findings were detailed and a table was presented differentiating pneumonia from effusive pleurisy.

Pneumonia in children occurs with an abrupt onset without chill (before the seventh year), but with vomiting or convulsions or other cerebral or meningeal symptoms. Cough is absent, since the bronchi are not involved; no sputum appears, and pain from the third to the fifth year, or, indeed, later, and also in adults, is referred to the abdomen, but without tenderness there. Pain is more important than increased respiration, which occurs with any elevation of temperature. Respirations number 80 under 2 years; in older children 50 or over. Crepitant râles are usually absent because of the superficial breathing caused by pain. Latency of signs is sometimes noted, as no bronchial breathing, no bronchophony, no dulness. Localization is more often central, in the upper lobes or migratory. Lysis is more frequent than in adults. In children pneumonia may be mistaken for abdominal disease, for pleurisy or brain affections. In alcoholics the disease is insidious, often without pain, cough or sputum, etc., and the lung symptoms may be overlooked, since the clinical picture of delirium tremens masks the signs of pneumonia.

Pneumonia secondary to tuberculosis, emphysema, arteriosclerosis, hepatic cirrhosis, nephritis, diabetes, typhoid influenza, diphtheria, anesthesia by ether, etc., is most frequently overlooked and the greatest care in chronic cases is necessary. Sudden death here and in general is often pneumonic.

Of other variations in the clinical course, the author mentioned the rarer forms, as abortive pneumonia, ephemeral pneumonia, relapsing or recurrent pneumonia. He discussed delayed or imperfect resolution; also local variations, massive pneumonia, etc., and as a final general statement he said that few diseases are recognized as easily as is fibrinous pneumonia, when careful consideration is given to its onset, symptoms, signs and evolution, and when, no symptom of pneumonia presenting, the patients with other disease are carefully, systematically and repeatedly examined.

Treatment of Pneumonia.

DR. JAMES B. HERRICK referred particularly to certain erroneous practices in the treatment of pneumonia, and argued for a simpler therapy and less free use of drugs. The expectant and symptomatic treatment is, for the present, seeing no specific remedy is known, the only rational one. The physicians can educate the laity to a knowledge of the self-limited nature of pneumonia, and a treatment as scientific as that in typhoid will be possible. He urged that oxygen be allowed to come in through the window, and not given entirely from the tank. No hard and fast rule as to diet should obtain; there should be individualization in this regard. Alcohol is seldom necessary. Hydrotherapy is proper for the reduction of temperature. Salt solution is of value, but its use ought not to be deferred until the patient is in extremis. Morphin is the best remedy to relieve pain and induce sleep, though it should, of course, be used with caution. Local applications are of doubtful value. They should not be so heavy or so light as to embarrass respiration. Bleeding is occasionally of benefit. The giving of many drugs for each trifling symptom is not indicated, and is often harmful. There is danger in the too free use of stimulants.

Discussion.

DR EDWARD F. WELLS stated that he had collected series of cases from the literature, which have been recorded during the past one hundred years, this table embracing at the present time about 400,000 cases, with a mortality rate of 22 per cent. or more. He believes the mortality of pneumonia is understated rather than over-stated.

In speaking of the diagnosis of pneumonia mention is frequently made of central pneumonias and the difficulty attending the diagnosis of these forms of the disease. A patient in full health is stricken by disease which prostrates him. He may lack cough and expectoration, still there may be fever, which is usually present. The prostration, the increased respiratory ring, the presence of leucocytosis of a peculiar character, the leucocytosis being due to an increase of polynuclear cells, would make the diagnosis clear to his mind in many cases in which the physical signs are in abeyance. He called attention to one observation which he has made, namely, that in cases of delayed physical signs, in the so-called central pneumonia, when the signs appear, one would find that almost invariably they are a little in front and just below the angle of the scapula. Casts are frequently found in the urine in pneumonia. Granular casts of pneumonia are remarkably uniform in size. He believes patients are usually fed too much in pneumonia. Pain in pneumonia declines in about three days, or subsides, regardless of what is done to relieve it.

DR. E. FLETCHER INGALS said the importance of not cutting off air is a point that should be impressed on all physicians in treating pneumonia. Pneumonia patients should not be fed in a routine manner. The proper administration of food is often neglected, and physicians frequently overlook the matter of feeding of the patient. He agreed with the essayist that opiates must be given if pain can not be relieved in some other way. Ordinarily, he believes bromid of ammonium will relieve insomnia if the drug is given early enough.

DR WALTER M. FITCH asked whether the antitoxin of pneumonia was of any value. Also, whether nuclein preparations are of any value in pneumonia other than producing a leucocytosis.

DR. EDWARD H. OCHSNER spoke of systematic strapping of the affected side in cases of pneumonia. In the great majority of cases that are thoroughly strapped early in the disease, the pneumonia disappears by lysis and not by crisis. His explanation is that the intoxication is not so sudden and severe, and it gives the patient a chance to produce immunity before he is completely intoxicated so as to cause death.

DR. M. HERZOG stated that pneumococcus septicemia is difficult to diagnose, but that this difficulty is largely done away with if a blood examination is made early, and attempts made to obtain pure cultures of the pneumococcus in the blood.

DR. B. W. SIPPY stated that cases that have the normal number of leucocytes, or less, were more likely to run a serious course.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, March 19, 1903.

The President, Dr. Andrew H. Smith, in the Chair.

Fetal and Infantile Typhoid Fever.

DR. J. LOVETT MORSE, Boston, said that conclusions could not be considered trustworthy that were founded on cases in which the diagnosis of typhoid fever had not been confirmed by a positive Widal reaction or the finding of the typhoid bacilli. Of fifteen cases, proved by autopsy and cultures to be genuine typhoid, ten were born dead or died at birth. Several persons had succeeded in proving experimentally the possibility of bacilli passing through the placenta, though it was not yet definitely known whether this could occur in a healthy placenta. Of twelve cases in which the organs were examined, the spleen was enlarged in four; in one there were healed ulcers and enlarged mesenteric glands; in one there was marked swelling of the liver with hemorrhages beneath its capsule. Intestinal lesions were not found in cases of intrauterine typhoid unless the infant lived for some time after birth. Infection of the fetus was not a necessary result of typhoid in the mother. The high mortality was explained by the septicemic nature of the infection. Statistics seemed to show that typhoid was uncommon at the age of 2 years, and that when it did occur at this early age it was in connection with other cases in the same house, or as a part of a large epidemic, thus suggesting that repeated exposure to severe infection was necessary for its production. Of thirty-two cases, twenty-three gave a positive Widal reaction, five were diagnosed positively by a bacteriologic examination, while in four cases both methods were employed. Sixteen of these cases giving a mortality of over 50 per cent. Of these sixteen, a typhoid eruption was present in sixteen, eleven showed abdominal distention, nineteen had diarrhea and five constipation.

Occurrence of Typhoid in Infants and Young Children.

DR. J. P. CROZER GRIFFITH, Philadelphia, presented this paper. He said the opinion was gaining ground that typhoid was not rare in infancy and childhood, and he had personally reported eighteen cases occurring in infants under two years and a half. Its onset and course were less characteristic than in the adult, and there was a tendency for the nervous symptoms to overbalance the intestinal symptoms. Walking typhoids were very common among these little patients. Vomiting was a comparatively common initial symptom, and epistaxis occurred about as often as in adults. Abdominal pain was common, rose spots were present in the majority of cases, and the spleen was probably always enlarged Desquamation often occurred, but there was nothing characteristic about it. Meningeal symptoms were often so marked as to confuse the diagnosis. The rise in temperature was rapid, with but little variation between the morning and evening, and the final fall was often so sudden as to appear critical in type. Both the mesenteric and the solitary glands were enlarged and elevated, but the tendency to intestinal ulceration was slight, which apparently explained the short duration of the disease. The value of the Widal reaction was inestimable in doubtful

cases occurring among infants and young children, but the failure to obtain this reaction did not necessarily exclude typhoid. It was particularly difficult to differentiate between influenza and typhoid. Intestinal hemorrhage was an infrequent complication and intestinal perforation was a great rarity. Relapses occurred about as often as in adults. Of 137 cases occurring in the Children's Hospital in the ten years prior to 1898 the mortality was 2.9 per cent., and in 295 cases occurring since 1898 it was 6.7 per cent. On the other hand, in a large series of cases of typhoid occurring in infants under two years and a half the mortality was 51 per cent. The Brand baths could not be fully employed in young children; even a plunge at 85 or 90 F. was often not well borne. Sponging should be tried first, and, if not sufficient, resort should be had to the graduated bath, beginning with a temperature of 90 and cooling it down to 85 F.

Symptoms and Etiology of Typhoid in Children.

Dr. A. D Blackader, Montreal, read this paper. He said that hand to hand infection was particularly prone to occur among young children. Out of 398 cases entering the Montreal General Hospital since 1900, 4 were below the age of 5 years, 19 were between 5 and 10, 32 were between 11 and 15, 89 were between 16 and 20, and 92 between 21 and 25 years of age. Only 3 cases occurred in persons over 50 years old. Of 100 cases reported by him in 1900, 4 were under 2 years, 13 were over 2 and under 6, 40 were over 6 and under 11, and 43 were over 11 and under 15 years old. The disease in children was milder in type and shorter in duration than in adults. The onset sometimes simulated pneumonia, but usually it was insidious. The temperature curve was usually atypical, and the continued fever of short duration. Abortive cases were not infrequent. The mortality was low; only one death occurred in his series of 100 cases, and in 50 consecutive cases in hospital there were only three deaths. Death usually was caused by some intercurrent affection. About the end of the first week the spleen could usually be palpated, and the typhoid roseola would be found in a large proportion of cases between the tenth and fourteenth days. Large ecchymotic spots on the skin justified an unfavorable prognosis. The pulse was usually rapid, but dicrotism was hardly ever observed in children under 10 years old. True meningitis in the course of typhoid was extremely rare. Ehrlich's diazo reaction, when present, was often an early help to diagnosis. The Widal reaction should be looked for every second day in doubtful cases. It was frequently not positive until after the tenth day.

Discussion.

Dr. L. Emmett Holt said that Dr. Griffith's opportunities for observing typhoid in infancy and childhood were exceptional. For example, in his hospital service at the Babies' Hospital, although examinations for the Widal reaction and cultures were made as a matter of routine in cases of continued fever, only three cases of typhoid fever had been encountered in a period of fourteen years. Undoubtedly typhoid was more a nervous than an intestinal disease in infants, and, hence, it was well to think of typhoid in every suspected case of meningitis. He had seen two or three cases in which the typhoid eruption was so profuse as to lead to the diagnosis of measles.

Dr. W. P. Northrup spoke of the great rarity of typhoid fever in infants, as shown by the fact that not a single undoubted case of this disease had been encountered at the New York Foundling Hospital in twenty-eight years. Moreover, Dr. Griffith had only succeeded in collecting from the literature of the whole world a comparatively insignificant number of cases.

NORTHWEST MEDICAL SOCIETY OF PHILADELPHIA.

Stated Meeting, held March 3, 1903.

President Dr. William Egbert Robertson in the Chair.

The retiring president, Dr. Wendell Reber, made an address, in which he reviewed the work of the society during the past year.

The Early Diagnosis of Pregnancy.

Dr. J. J. Gurney Williams directed attention to the frequency with which this condition is overlooked during the first ten weeks, owing to the atypical symptoms presented. He recommended careful bimanual examination and observation of both the objective and the subjective signs. In the majority of cases he feels that the patients are led to consult the physician on account of the amenorrhea, for which there are many other causes than pregnancy, which causes he considered under three heads: 1. Those cases in which menstruation has never taken place, which, he felt, was most likely to be caused by some defective development of the uterus or ovaries or some constitutional states, such as chlorosis, anemia or phthisis. In many of these cases menstruation does not begin until the assumption of marital relations.

2. In the second and the largest class of cases the menstruation has been suppressed. Previous regularity or irregularity and a history of any pelvic operations should be considered, as even dilatation and curettement may cause one or two periods to be missed.

3. In the third class the blood is retained within the uterine cavity or vagina, as from atresia or imperforate hymen, and a physical examination will reveal the condition. Among the various causes for the suppression of menstruation are change of climate, as the country girl coming to the city and starting to work in a mill, fear of illicit pregnancy, desire for offspring, great mental activity, catching cold or getting the feet wet just prior to an expected period. The use of bromids in epilepsy is also said to cause this condition, and two cases had come under the author's observation which had suffered from amenorrhea for two months after using a mixture of zinc sulphate and digitalis "to prevent smallpox." Supra-involution following labor or miscarriage and injections to prevent conception may also cause this condition, and, as a point of diagnostic import, it should be borne in mind that amenorrhea arising from any other cause than pregnancy usually manifests itself in some constitutional disease, such as anemia, general debility and weakness.

The mammary signs are not constant and often misleading, but in pregnancy the nipple is usually more prominent, the areola darker, and Montgomery's tubercles enlarge, and if, in combination with these symptoms, there is frequent micturition, this is a valuable adjunct to diagnosis. Nausea varies greatly in time and severity.

The author felt that the most important reliable objective symptom is the change in the shape of the uterus, which in the virgin is pyriform, but when pregnancy occurs the fundus rapidly enlarges and changes in form, and, as this examination can only be made between uterine contractions, repeated examinations may be necessary to find the uterus at rest. Hagar's sign in conjunction with the other symptoms is very valuable after the second month; softening of the cervix is not constant and may be caused by metritis. The bluish discoloration of the vagina just posterior to the urethra can be observed as early as the fifth week and is of considerable value, and when produced by a fibroid or pelvic congestion is of a lighter blue. A cervix lower than normal and increase in weight of the uterus are important symptoms, and salivation, stimulated or perverted appetite, a feeling of drowsiness and constipation are common symptoms, although valueless except in conjunction with others

In regard to the diagnosis of ectopic pregnancy, in every case in which there is vaginal bleeding, or abdominal or pelvic pain, and the woman is presumably pregnant, a careful bimanual examination should be made, as the cases of this condition in which the diagnosis is not made are those which do not present the typical symptoms, such as sudden onset of pelvic pain, accompanied by a bloody discharge, with shreds, a leaky skin, rapid pulse and, probably, tympanites

Discussion.

Dr. Walter F. Woods directed attention to three classes of cases, in which he had found it exceedingly difficult to make an authentic early diagnosis of pregnancy: 1, Pregnancy occurring during lactation; 2, amenorrhea occurring during the progress of some debilitating disease; and 3, where the patient

intentionally tries to deceive the physician. The cause of the difficulty in the first group is that the uterus is somewhat involuted following delivery, requiring from six weeks to three months to return to normal, and if amenorrhea occurs during this period, the abnormal position of the uterus is apt to conflict with the differential diagnosis. In the second class of cases, it is necessary to study all the symptoms which the primary disease might produce and make a diagnosis chiefly by exclusion. Cases of the third class require careful investigation, as they are prone to give a false history of the menstrual periods and other symptoms. The patient's history should be carefully noted and considered in conjunction with the physical examination, which should be made in all cases, and a familiarity with the patient's habits, mode of thought and the physical condition of her genital organs is of value, which places the family physician in a better position to make the diagnosis than one who is called in for that especial purpose.

The nervous phenomenon manifested should be given consideration, as in many instances a naturally nervous patient will become of a composed temperament during the first few weeks of pregnancy, and one who usually has a placid disposition will frequently become very irritable. The reflex gastric disturbance which may occur at different times during the day is a valuable symptom, and usually before the morning sickness appears there is an undue craving for certain articles of food, while the appetite, as a whole, may remain about normal. In many instances flesh is assumed quite rapidly. To the family physician who is familiar with the shape and position of the patient's uterus, the change in the position and size during the first few weeks of pregnancy may be an important aid in diagnosis. Another important factor is the softening of the cervix, and, while this occurs at each menstrual period, it disappears shortly thereafter unless a pregnancy has taken place, in which event it is continuous. This sign is especially valuable in primipara, while in multipara the variation in the cervix from lacerations, etc., frequently obscures the Hagar sign. The condition of the mammary gland, such as deepening of the color of the nipple and enlargement and pricking sensation in the gland are signs which should be studied in conjunction with the others.

One of the most valuable signs, he considered, was the irritable bladder, and, although the menstruation frequently causes a more frequent desire to pass urine, the condition is continuous if caused by pregnancy. The purplish or bluish condition of the vagina should be looked for, and although this may be brought about by pathologic states, it usually occurs earlier in pregnancy than in the other conditions, the reason being that in pregnancy the blood is brought to the uterus primarily, while the pathologic conditions simply dam up the blood in the uterus so as to produce this sign. Shaeffer's sign, he stated, he had never been able to demonstrate.

DR. J. THOMPSON SCHELL viewed as the most important symptom the marked anteflexion of the uterus which is usually present. He felt that by carefully considering the added weight to the uterus, the increased amount of vaginal and cervical secretion, with beginning softening of the cervix, the fact that the cervix is generally partially prolapsed, the uterus further down in the pelvis and heavily supported, and by careful vaginal and rectal examination and the so-called Hagar's sign one can say that the woman is probably pregnant. The beginning of a violet color in the vagina later becoming blue is of value, and by three or four examinations, at intervals of a week, the diagnosis should be made with reasonable certainty.

In ectopic pregnancy, an early diagnosis is of vital importance, and this condition may exist without the presence of any of the customary signs, and the only symptom may be shock. It was recommended that in all cases where the patient complains of amenorrhea, pain in the abdomen and a little leaking from the vagina, that she be examined under an anesthetic. A case was reported of a woman who had been married for a number of years; had been sterile for seven years, and up to one month prior to the time she was seen had menstruated regularly without pain, at which time she missed a period. There was some pain in the lower portion of the abdomen, but no great evidence of shock and her temperature was normal. An examination under an anesthetic was decided on, a vaginal examination made, and an ectopic pregnancy discovered.

In regard to Shaeffer's sign, it was considered absolutely unreliable, except in conjunction with other symptoms, and in the majority of cases was believed to be absent.

DR. SAMUEL WOLFE believed it practically impossible to make a positive diagnosis in the early months, but felt that the family practitioner who was more or less familiar with the physical condition and history of his patients could generally be fairly certain of his diagnosis.

DR. W. WAYNE BABCOCK reported cases, the first of which was a woman who had been sterile for eight years, and had been operated on for laceration of the cervix, after which she developed retroversion of the uterus, which gave her a great deal of trouble, operation being advised to relieve this condition. This was, however, deferred for a number of months, and finally she missed a period and passed eight weeks over her time, when an examination revealed the uterus in a retroflexed position, with the fundus very large and soft and the cervix very small, leading to the conclusion that she was pregnant. On re-examination a week or two later, the mass was found to be somewhat larger, but, by feeling carefully, could be felt what appeared to be the normal fundus, and a division was apparent between the mass behind the uterus and the cervix. Pain in the pelvis was complained of and a week or two later, extra-uterine pregnancy being suspected, an operation was suggested. On opening the uterus what was supposed to be the fundus of the uterus was found to be a small fibroid, the whole uterus being studded with fibroids and, as they were directly in the path of the child and were growing rapidly, the whole organ was removed.

Another woman had been wearing a stem-pessary for two years to prevent conception, removing it during the menstrual period. The pessary was slightly longer than was necessary. She complained of constant bleeding, which she seemed unable to stop. She had a distinctly enlarged and soft uterus, but pregnancy was not thought of. A curettement was done, and the character and amount of material removed indicated that a pregnancy had taken place, in spite of the precaution, which the speaker thought would create a good field for the development of malignant disease.

DR. WILLIAM L. PEPPER stated that he had frequently noticed that women in whom sexual desire is very great before pregnancy will lose all desire during gestation, while those in whom sexual desire is not usually so great, will become abnormally sexually excited during pregnancy.

DR. J. EDWARD WALLIS felt that there were no signs sufficient to make a positive diagnosis until the end of the third month.

DRS. L. C. PETERS, I. C. GERHARD, W. H. THOMAS and HUGH P. MCANIFF also took part in the discussion and reported cases. One of these was of menstruation throughout pregnancy, others were of difficult diagnosis in wasting diseases.

DR. CARLE LEE FELT reported the case of a woman who had borne three children, examination after the birth of the third child revealing laceration of the cervix. A curettement was done, and a short time afterward she stated to her physician that she was two months pregnant. Seven months after this she was delivered of a full term child, which proved that she must have been pregnant at the time of the operation.

DR. J. H. GURNEY WILLIAMS stated that he had made a number of observations with the urine of pregnant patients, and had found that after the first twenty-four or forty-eight hours a skin-like substance would form on the top of the urine, and if it was held up to the light particles could be seen rising therefrom. This he had not observed in any urine except in cases of pregnancy. The history and symptoms he believed to be practically worthless, unless confirmed by the examination. Pinkish vaginal discoloration just posterior to the urethra is a sign of considerable value.

The vaginal incision in ectopic pregnancy is not wise, as in the majority of cases it necessitates two incisions in order to control the hemorrhage.

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Pruritus.

Leredde, in the "Journal des Praticiens," advocates the use of acetic acid in the following combinations:

℞.	Acid. acetic.....gr. xx	1	30
	Lanolin.....3i	4	
	Vaselin.....3iii	12	
M. Sig.: Apply locally; or:			
℞.	Acid. acetic.....gr. xx	1	30
	Vaselin.....3ii	8	
	Lanolin.		
	Pulv. amyli, āā.....3iii	12	
M. Sig.: Paste; apply locally.			

He also suggests the use of carbolic acid in one to three per cent. solutions on compresses.

Tincture of benzoin may also be employed in the following combination:

℞.	Lanolin.....ʒi	30	
	Vaselin.....3iv	15	
	Aquæ.....3i	4	
	Tr. benzoini.....3i	4	
M. Sig.: Ointment; apply locally.			

Camphor is an excellent anti-pruritic and may be used in either of the following prescriptions:

℞.	Chloral hydratis.....gr. xv	1	
	Linimenti camphoræ.....3ii	8	
	Lanolin.....ʒiii	90	
M. Sig.: Ointment; apply locally; or:			
℞.	Zinci oxid.		
	Cretæ		
	Linimenti camphoræ		
	Aq. calcis, āā.....3vi	25	
M. Sig.: Apply locally.			

The author also recommends a weak watery solution or ointment of ichthyol, one or two drams to the ounce. He has also found resorcin a remarkable anti-pruritic when employed in watery or alcoholic 2 to 5 per cent. solution.

Cough.

A prescription which has proved valuable, especially in case of young children, is as follows:

℞.	Codein. sulphatis.....gr. vi		40
	Sp. aeth. nitrosi		
	Syr. ipecac., āā.....3ii	8	
	Syr. lactucarii (Aubergier) q. s. ad....ʒiii	90	
M. Sig.: Half teaspoonful to one teaspoonful as required for cough.			

In the irritating cough which so often follows influenza the following preparation is recommended in the "Canadian Journal of Medicine and Surgery":

℞.	Heroin. hydrochloratis.....gr. iii		20
	Syr. acaciæ.....3vi	25	
	Aquæ q. s. ad.....ʒiv	120	
M. Sig.: Two teaspoonfuls 3 or 4 times a day.			

Alcohol in Fevers.

Martinet, in "La Presse Médicale," gives a formula which is intended to serve as a guide in the rational administration of alcohol in fevers, whereby the tissue waste may be forestalled:

℞.	Tr. cinnamomi.....3i	4	
	Sp. sacchari (old)		
	Syr. simplicis, āā.....ʒiii	90	
	Aq. tileæ (Linden water).....3x	40	
M. Sig.: Tablespoonful every two hours.			

The "Canadian Journal of Med. and Surg." recommends this editorially and urges that it certainly would be satisfactory to the practitioner, and should be in the best interests of the patient and his family, if alcohol, accurately measured according to the requirements of the individual, were administered as carefully as any other medicine. If the patient has scruples against liquors, medicinal dosage, as in the prescription quoted, may avoid unpleasantness.

Carbolic Acid for Erysipelas.

Seneca D. Powell, New York, applies 95 per cent. carbolic acid in erysipelas, and as soon as the skin turns white he applies alcohol to check the action. Large surfaces may be thus treated without harm. Temperature and other symptoms are rapidly and markedly alleviated. This treatment also lessens the danger of infection to others.

The "Dietetic and Hygienic Gazette" describes another treatment for erysipelas. It is to cover the area and a margin on the surrounding skin with a thick layer of white vaselin, cover this with linen and bandage to hold it in place. Apply twice daily. Its advantage over iodin applications is the absence of pain and irritation.

Removal of Odors from Hands.

Dr. Powell also recommends carbolic acid to remove the foul odors that cling to the hands after opening abscesses or after work in autopsies. The acid should be used in the strength of a dram to the ounce of water.

Typhoid Fever in Infants.

J. P. Crozer Griffith, in the "Medical Record," says: The bath method of Brand carried out with exactitude is not applicable to young children. Even a tepid plunge of 85 or 90 F. is often not well borne by older children. His custom is to employ sponging first, because it is often sufficient; if not, a graduated bath is used, beginning at 90 F. and cooling it down to 85 F. This is the safer plan. Sometimes a warm bath of 95 or 100 F. is useful, and the same is true of the abdominal ice-bag. Hydrotherapy should never be used in young children as a necessary routine, and the prolonged sponging of a struggling child is neither useful nor judicious.

Codein in Insanity.

In a recent Paris thesis by Jules Clausse, says the "N. Y. Med. Jour.," the author sets forth the great advantages of the employment of codein as a calmative in cases of melancholia and in those of any psychical disturbance characterized by derangement of the general sensibility, by anxiety, and by moral suffering. Its effect, he says, is soon manifested in the improved facial expression and the subsidence of the feelings of moral anguish. For melancholiacs it is the hypnotic par excellence, since it overcomes the causes of their sleeplessness. Moreover, it is devoid of the unpleasant after-effects of opium and morphin. It does not diminish the secretions or cause constipation or the impairment of appetite or the unpleasant sensations on waking that opium and morphin are prone to give rise to. The dose, however, must be scrupulously regulated to suit the case, and the drug is positively contraindicated in cases of intense excitement and in maniacal conditions.

A Mouth Wash.

Pruyn recommended to the Illinois Dental Society the following as a mouth wash:

℞.	Boracic acid.....3iii	12	
	Oil cassia		
	Carbolic acid		
	Chloroform, āā.....3i	4	
	Alcohol.....ʒiiiss	105	
	Oil peppermint, ...drops x		65
	Glycerin, to make..... fl. ʒviii	240	
M. Sig.: Add one-half teaspoonful to one-half glass tepid water as a mouth wash.			

This is recommended in inflammation of the mucous membrane wherever located, but if used through the nose it should be weaker than for a mouth wash.

The Abuse of Lavage of the Stomach.

The "N. Y. Med. Jour." says: New therapeutic measures that in the least answer the purposes they are alleged to serve are too apt to be carried to extremes, and it is well when modera-

tion in their employment is advised. This may be said, we think, of lavage of the stomach. It is not always the innocent procedure that it passes for, as it occasionally gives rise to collapse. It should be resorted to only on definite indications and employed in moderation.

Influenza.

Hare's text-book on therapeutics, last edition, gives a valuable summary of the treatment of influenza. Some of the suggestions are as follows:

To abort the attack in first few hours:

℞.	Tr. aconit. rad.	℥ss	2
	Spts. ætheris nitrosi	℥iii	4
	Potassii citrat	ʒiii	4
	Aquæ q. s. ad	℥i	30

M. Sig.: One teaspoonful every four hours, during first day of the attack.

For the irritative cough in first stage:

℞.	Tr. benzoini comp	℥i	4

Sig.: Add to one pint of boiling water, and inhale the steam.

For the cough in the height of the attack:

℞.	Ext. cannabis ind	gr. ¼-i	.015-.6

Or:

℞.	Codeinæ sulph	gr. ¼-i	.015-.6

Sig.: Every three or four hours.

For the bronchitis in the early stage:

℞.	Vini ipecac	℥ii	8
	Potassii citratis	℥ii	8
	Syr. pruni virg	℥ii	60

M. Sig.: One teaspoonful every two hours.

For the bronchitis in the later stages:

℞.	Ammon. chlor	gr. xl	3
	Tr. cubebæ	℥i	30
	Syr. pruni virg. q s. ad	℥iv	120

M. Sig.: One tablespoonful every three hours.

For the insomnia:

℞.	Chloral hydratis	gr. xv	1

Or:

℞.	Chloralamid	gr. xxx	2

Or:

	Sulphonal	gr. xx	1.3

Sig:. At one dose.

For stimulation, throughout the attack:

℞. Strychninæ sulph. up to .03 (gr. 1/20).

Sig.: Every four hours. (It is preferable to use smaller doses more frequently, e. g., gr. 1/40 every two hours.)

For the vertigo and dizziness:

℞.	Ext. ergotæ fld	℥ss	2
	Sodii bromidi	gr. xx	1.4

M. Sig.: Take at one dose; repeat q. 3 hours.

For the constipation in the early stages:

℞.	Castor oil	℥ss	15

Or:

℞.	Magnesii sulph	℥ss	15

Or:

℞.	Magnesii citratis	℥ss	15

Sig.: at one dose.

For the constipation after the attack: One teaspoonful of fluid extract of cascara at night.

Anders suggests for the laryngobronchial irritation of influenza:

℞.	Codeinæ sulph	gr. iv	.25
	Ammon. chloridi	ʒxv	20
	Syr. pruni virg	℥ii	60
	Spts. junip. comp. q. s. ad	℥iv	120

M. Sig.: One teaspoonful every two or three hours.

The Internal Uses of Potassium Permanganate.-

A. Khoury reports, in the "Jour des Praticiens," as quoted by "Amer. Med," four patients with painful dysmenorrhea who were cured, and three patients with anemia greatly improved by the administration of potassium permanganate. It was given in doses of from 5 centigrams to 0.26 gram. (5/6 to 4 grains) usually in pills, which have the advantage of not staining the mucous membrane of the mouth. In all cases this drug was well borne by the stomach. It caused no constipation or diarrhea; in only one case was the urine tinted a light pink. Menstruation does not counterindicate its use.

Medicolegal.

Reading or Proving Contents of Medical Works to Jury.—The furthest that the Supreme Court of Illinois has gone in respect to reading medical works to the jury, the Appellate Court of Illinois, First District, says, is to hold that if an expert bases his opinion on the work of an author, the work may be read in evidence to contradict him. And if it would not have been competent for counsel to produce and read to the jury medical books, much less was it competent, the Appellate Court holds, in the case of the Chicago City Railway Company vs. Douglas, to attempt to prove the contents of such books by witnesses testifying solely from memory. The testimony of medical expert witnesses as to what others had written or spoken in regard to the subject matter of the inquiry, was mere hearsay, and incompetent.

Care of Soldier in Private Infirmary.—The case of Davis vs. United States was brought in the United States District Court in Alabama to recover the reasonable value of the board, lodging, medicines, medical attention and nursing of a soldier in the service of the United States who was taken ill with typhoid fever and was by the direction of his captain conveyed to a private infirmary for medical treatment and attention, there being no army surgeon near the place whose medical services could be obtained for him, and no army hospital to which he could be sent. Section 1452 of the army regulations, promulgated Oct. 31, 1895, provides that: "When medical attendance is required by an officer or enlisted man on duty, and the attendance of a medical officer can not be had, the officer, or if there be no officer present, then the enlisted man may employ a civilian physician. and a just account for his services and the necessary medicines will be paid by the medical department." Section 1457 provides that "accounts for board, lodging, nursing and medical attendance of sick soldiers in private hospitals will be sent to the surgeon-general for settlement." But in this case there was no valid express contract, as required by act of June 2, 1862, for the services rendered. However, the court is of the opinion that the captain acted within the line of his authority under the army regulations, in sending the sick soldier to the infirmary, from which there arose on the part of the United States government an implied contract to pay the fair value of the services rendered, as claimed.

Not Required to Have Limb Rebroken and Reset.—In the malpractice case of Morris vs. Despain, where a judgment for damages is affirmed by the Appellate Court of Illinois, Second District, a woman 69 years of age, in good health, fell and suffered an oblique fracture of the left femur, two or three inches below the hip joint. Two physicians attended her. They reduced the fracture and put on a roller splint. When they discharged her the injured limb was inverted or turned in toward the other, according to her proof, ninety degrees, but according to that of the physicians only twenty-five or thirty degrees. She claimed that the condition of her leg was brought about by careless and unskilful treatment. The physicians claimed that they exercised care and professional skill, and that what they did was good practice; that prior to the use of the fracture box they desired to use a system of weights to avoid the injury complained of, but that the patient would not permit them to do so, and that she also disobeyed their instructions. Two trials were had; the first resulting in a verdict for $1,000 damages; the second for $950. On the questions whether she obeyed instructions, and whether the treatment pursued was the proper treatment to prevent inversion or not, the court says that the evidence was in hopeless conflict, but that there was abundant to sustain the verdict. After the union between the bones was complete and the patient had discovered the condition of her leg, she requested that an-

other physician be called in. This physician being called, advised that the only way by which the limb could then be straightened would be by breaking the bone and resetting it, but this the patient declined to allow to be done. The trial judge gave an instruction for her which told the jury that even though they should believe, from the evidence, that the limb might have been straightened by being broken again and reset, yet if the evidence showed that by reason of the want of ordinary care and skill on the part of the two physicians, the limb was permitted or caused to be crooked, and that ordinary skill and care on their part would have avoided the injury, her refusal to have her limb rebroken and reset was no defense to any injury caused by their want of ordinary skill or care. The Appellate Court holds that the instruction was properly given. It holds that she was not required to submit to have her limb rebroken in order to relieve them from liability for lack of ordinary care and skill. Moreover, there was evidence tending to show that such an operation would be attended with great pain and that at her age and in her physical condition there was great danger that it would prove fatal to her. The law did not require her to risk such danger before she could sustain her suit.

Mississippi Medical Practice Act and Osteopathy.—In the Mississippi case of Hayden vs. State the former party was indicted for practicing as a physician without first having been examined and obtained a license so to do. The admitted facts were that he was a graduate of a school of osteopathy and practiced it. That in treating diseases, and in his treatment of the witnesses for the state in this case he did not use any drug or medicine, but his treatment consisted of manipulating scientifically the limbs, muscles, ligaments and bones which were pressing on the nerves of the blood supply. This treatment was had so that Nature would have free action. That in his treatment of diseases or pains he was confined solely to his manipulation as above described. That for said services to said witnesses he received pay. That the witnesses were being treated for rheumatism, and claimed that they had entirely recovered as a result of that treatment. The circuit judge instructed the jury that, if they believed the admitted facts, they should convict the party. This they did, and thereon the judge imposed a fine of $20 on him. The Supreme Court of Mississippi says that the sole question was whether, under Chapter 68, Acts 1896, an osteopath is required to be examined and licensed for the practice of his branch of the healing art. The act of 1896 provides: "That the practice of medicine shall mean to suggest, recommend, prescribe or direct for the use of any person, any drug, medicine, appliance or agency, whether material or not material, for the cure, relief or palliation of any ailment or disease of the mind or body, or for the cure or relief of any wound or fracture or other bodily injury or deformity or the practice of obstetrics or midwifery, after having received, or with the intent of receiving therefore, either directly or indirectly, any bonus, gift, profit or compensation." It was perfectly manifest, the court thinks, from the agreed statement of facts, that the party used neither drug nor medicine, as meant by the act. It was equally manifest that the legislature, by the use of the words "appliance and agency," did not intend to include such treatment as he gave the state witnesses. Continuing, it says that its attention has been called to no statement of osteopathic treatment in all the literature on this subject which characterizes the treatment of an osteopath of his patient as an appliance or agency. There is an incongruity in such application of such words. Osteopaths themselves do not speak of their manipulation of the nerves, ligaments, bones and other parts of the human body as being agencies or appliances of any sort or in any sense. In any strict and proper use of such words they can not be so denominated. If one not an osteopath directs a blow at their art it is becoming that he use a term of description not to be mistaken. The Supreme Court concludes that the act of March 19, 1896, was not intended to regulate the practice of osteopathy in Mississippi. It says that the course of study and examination prescribed in the law of that state on this subject seems to mark it out as curriculum of the allopaths. It at least suits them in many respects, but its chemistry and materia medica are not specially adapted to assist the practice of osteopathy. They make no use of the immense learning contained on these subjects, so highly valued by the regular physician. It appears to the court that the Mississippi legislation on the subject of the practice of medicine has been framed by the allopaths to suit their views of the medical art, and with the laudable design of excluding from the practice the unskilful and the ignorant; and it was not intended to set up a universal standard of therapeutics, from which none could depart. Courts in other jurisdictions where similar statutes prevail have led the way for the decision in this case. And the court says that while its own views of the subject would probably have led it to the conclusion it has reached, yet, if the case had been otherwise, it should have felt itself strongly constrained by the authority and reasoning contained in them. It refers to State of Ohio vs. Liffring, State of Rhode Island vs. Mylod and Nelson vs. Board (Kentucky). Alabama, with a statute widely divergent from that of Mississippi, it says, holds another view. But Bragg vs. State of Alabama sheds no light on the construction of the Mississippi statute. It adds that a wise legislature some time in the future will doubtless make suitable regulations for the practice of osteopathy, so as to exclude the ignorant and unskilful practitioners of the art among them. The world needs and may demand that nothing good or wholesome shall be denied from its use and enjoyment.

Current Medical Literature.

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

American Medicine, Philadelphia.

March 28.

1 *The Psychic Nature of Some Disturbances of the Acts of Urination and Defecation. Charles J. Aldrich.
2 *The Prevention and Outdoor Treatment of Pulmonary Tuberculosis. Frank Warner.
3 Postpartum Subinvolution. James E. King.
4 *Course of Diseases During Pregnancy. E. Castelli.
5 *Gastroptosis and Gastrectasis. E. S. Fogg.
6 A Diagnosis by Postmortem Laparotomy. C. A. Drew.
7 Glimpses of the Practice of Medicine and Diseases in the West Indies. (To be continued.) Nicholas Senn.

1. **Psychic Disorders of Urination, Etc.**—In this article Aldrich reports a number of cases of curious psychic embarrassment connected with the acts of urination and defecation, the latter being far less frequent than the former. He thinks innate modesty may be sufficient to explain the condition in some of these cases, but others are not so readily explained.

2. **Tuberculosis.**—The subject of tuberculosis is reviewed by Warner, who notices the theory of its contagion, though with proper care, this can be of but little importance. The lowering of vital resistance is undoubtedly the greatest cause of vulnerability to the infection which few altogether escape. He reviews the various methods of treatment, and notices the arguments that would make bovine tuberculosis infectious to human beings. There is a good deal of hopefulness in Behring's antituberculosis vaccination, though as yet it is too early to decide in regard to its efficacy.

4. **Diseases of Pregnancy.**—Castelli reviews the circulatory and heart lesions that may be associated with pregnancy and thinks that the physiologic condition may possibly explain the tendency to primary heart lesions, hence, we should adopt prophylactic measures during pregnancy to guard against their possibility. The patient should have a great deal of rest, especially if weak and anemic, and lack of exercise must be substituted by massage. To counterbalance the impaired respiratory power of the blood corpuscles and the consequent hemolysis, a cytogenic treatment could be adopted during the last months of pregnancy. The influence of pregnancy on any coexisting heart disease is also noted. It renders the existence of these disorders more serious and often disastrous. He would be inclined to advise against marriage more in case of mitral than aortic lesions, not giving harsh opinions, but talking sensibly to the patient, showing the dangers, prescribe a program of life, and if necessary, caution her against child-

bearing. If the cardiac troubles become dangerous to the life of the pregnant woman labor should be accelerated or brought about prematurely. In conclusion he speaks of the varicose veins of the pregnant condition.

5. **Gastroptosis and Gastrectasis.**—In these conditions Fogg thinks the two operations most rational and efficient are the Beyea operation in gastroptosis and gastroplication for gastrectasis. He reports a successful case of the former.

New York Medical Journal.

March 28.

8 Syphilitic Pseudotabes—Report of a Case; the Differential Diagnosis of Tabes. (To be concluded.) Joseph Collins.
9 *Streptococcus and Staphylococcus Bronchitis. Joseph M. Patton.
10 *Intestinal Resection and End-to-End Anastomosis, with the O'Hara Forceps, in a Case of Tubo-ovarian Abscess with Appendicitis; Recovery. George G. Ward, Jr.
11 *The Special Dispensary as a Factor in the Combat of Tuberculosis as a Disease of the Masses. S. A. Knopf.
12 *Opium in Surgery. Edward W. Lee.
13 *Retinoscopy. Daniel H. Wiesner.
14 *On the General Characteristics of Corneal Astigmatism. H. Davison Sarll.

9.—See abstract in THE JOURNAL, Feb. 14, p. 464.

10. **Intestinal Resection.**—Ward reports a case, calling attention to the advantages of the O'Hara forceps first described in the "American Journal of Obstetrics" for July, 1900. Their advantages are summed up by him as: 1. Only one forceps is required for any size of intestine; 2, it is not necessary to ligate or clamp the bowel as in the button or other methods, as the forceps keep the intestine closed at the site of resection throughout the operation; 3, no manipulation or work inside the bowel is done, so that the advantage of cleanliness is one of the strongest points in its favor. Lastly, the perfect control of the work, the slippery intestine being held with ease and allowing accuracy of suturing, and the general simplicity of the apparatus.

11. **Tuberculosis.**—Knopf is in favor of special provision for tuberculous patients in existing dispensaries, but still more for special tuberculosis dispensaries after the pattern of the Emile Roux foundation at Lille, France, and the one esablished in Havana by the United States government. He thinks there may yet come a time when with the modern sanatoria and some seaside sanatoria for tuberculous children, the tuberculosis dispensaries he advises will be valuable distributing and diagnosing points.

12. **Opium in Surgery.**—This article is a plea for opium in many conditions in surgery. Lee holds that while it should be used judiciously and its injudicious administration is injurious, it has special indications. In fractures, for example, and in severe burns, in trauma or surgical shock, if accompanied by pain or hemorrhage, and also before the administration of anesthetics. This is particularly true, he says, if the individual is addicted to the use of alcoholic stimulants or suffering from fever or nervousness. He notes the tendency to prejudice against it in abdominal surgery, but where it is possible to clean out the intestinal tract, relieve the lungs, kidneys, and liver of any co-existing congestion, he does not believe a little morphin to stop pain is going to do the harm credited to it. Of course, great caution should be used. It is the best internal hemostatic in the treatment of hemorrhage, and it often relieves obstinate and exhausting vomiting after anesthesia. In the first twenty-four hours after operation the pain becomes so severe it causes uncontrollable restlessness, and morphin should be used to relieve it. In certain conditions he believes in judicious administration of opium in peritonitis regardless of its cause. He gives examples of the reversal of the opinion in regard to opium when the surgeon is himself the operated on instead of the operator.

13. **Retinoscopy.**—Wiesner's article describes the conditions of the eye which may come before the practitioner, and endeavors to present a test for refractive conditions, calling attention to the abuses of refraction in the hands of unskilled and ignorant opticians.

14. **Corneal Astigmatism.**—Sarll describes the conditions of astigmatism, noticing some of the salient features, subjective symptoms, methods of diagnosis and correction.

Philadelphia Medical Journal.

March 28.

15 *The Increase of the Use of Cocain Among the Laity in Pittsburg. Thomas G. Simonton.
16 *The Use of the Electrothermic Angiotribe in Lieu of the Employment of Ligatures in the Open Operation for the Relief of Varicocele. Orville Horwitz.
17 Additional Notes on Organacidia Gastrica. Mark I. Knapp.
18 *Mouth Infection, Due to Natural Teeth. (To be continued.) D. D. Smith.
19 *Psychopathic Epidemics. (Continued.) John B. Huber.

15. **Cocain Addiction.**—The increase of cocain addiction is noticed by Simonton, who gives some of his own experiences, mentions symptoms and treatment. He finds that the drug produces an exhilarating effect which rapidly disappears, followed by increase audition and in habitues by auditory hallucination. He believes the habit is one of the most difficult of all drug habits to cure, and from his investigations in drug stores he finds that the sale is very largely increasing, especially among the colored population who are the largest users of it at the present time. It is his honest belief that 3,000 ounces is not an unusual amount to pass over a single counter in a year, but actual figures are hard to obtain. One druggist admitted, in the presence of witnesses, that he sold 40 to 50 ounces a month. He suggests a strict law against the sale of cocain, except on prescription of reliable physicians, who are personally known to the druggist, and prohibiting physicians from giving it to those who are thought to be drug fiends.

16. **Varicocele.**—Horwitz recommends the Downes' electrothermic angiotribe as described in THE JOURNAL for Aug. 17, 1901, for the open treatment of varicocele, reporting a case of unusually large varix, thus treated. He says it has decided advantages over the simple angiotribe in being less crude and dangerous, in less danger of secondary hemorrhage and thrombus, lack of pain after operation and less danger of orchitis.

18.—This article has appeared elsewhere. See THE JOURNAL of March 14, ¶83, p. 739.

19. **Psychopathic Epidemics.**—Huber notices in this article the Schlatter, Francis Truth, osteopathy, Eddyism and other delusions. He considers that Schlatter was probably honest, but insane. He remarks as to the factors which produce these psychopathic epidemics, that imitation is far the most potent. He has investigated Eddyite cures and has not come across a single one of a serious disease, which they claimed to have thus relieved.

Medical News, New York.

20 *Spinal Concussion, So-called. Carl E. Black.
21 A Brief Consideration of the Mechanism of Mental States Encountered in Alcoholic Insanity, with Illustrative Cases. W. K. Walker.
22 *Scope of Vaginal Section. H. J. Boldt.
23 *The Scope of Vaginal Section. Hiram N. Vineberg.
24 *How Easily We Can be Mistaken in the Diagnosis of Cancer of the Stomach. Mark I. Knapp.
25 *The Operative Treatment of Fracture of the Patella. Russell S. Fowler.
26 Some Physiological Observations on a Crustacean Heart. George V. N. Dearborn.

20.—See abstract in THE JOURNAL, xxxix, p. 1,132.

22. **Vaginal Section.**—Boldt's article is the same in substance as that abstracted in THE JOURNAL of March 28, ¶84, p. 875.

23. **Vaginal Section.**—Vineberg considers this subject exclusive of vaginal hysterectomy and also of operations performed for the correction of uterine displacements by this route. Excluding these, he finds the scope of the operation in pelvic abscess, pyloroplasty and ovarian abscess, conservative surgery in diseased adnexa, in cases of ovarian cyst, in myomectomy for small fibroid growths of the anterior wall or the fundus of the uterus, in ectopic pregnancy under certain conditions, as: 1. In obscure cases to aid in forming the diagnosis, and 2, in cases where there is no further hemorrhage and the already effused blood has formed a hematocele in the Douglas cul-de-sac or at the base of one of the broad ligaments. In many of these cases vaginal section and drainage prove to be curative. In others, again, the affected tube is the source of future trouble which may require its removal with the corresponding ovary. In case of pyosalpinx and ovarian abscess he would operate by this

method only when the sac is easily reached and can be removed entire, and when it is not large and can be removed readily by the anterior incision, and sometimes in the acute stage to tide the patient over the dangerous period. The locality of the pus collections, in abscess and salpingitis, of course, must guide the operator.

24. Cancer of the Stomach.—Knapp gives a hypothetical and two actual cases, one of his own observation and one taken from Obrastzow's experience, which show the difficulties sometimes encountered in recognizing the true condition of things in certain cases of gastrosia fungosa.

25. Fracture of the Patella.—Fowler considers a certain number of cases in which operative treatment is contra-indicated such as when there is intercurrent disease of such a nature as to prohibit operation, and when the patient prefers to pass the remainder of his life partially disabled rather than to take the chances of a certain amount of risk of life. Longitudinal fractures do not require operation. In comminuted fractures it is unjustifiable except in selected cases when circumsuture may be employed; neither do transverse fractures in which rupture of the capsule has not occurred, require operation. This alone, however, is very rare and is revealed by slight separation of the fragments, absence of tilting of the fragments, and but slight effusion in the joint. The aponeurotic structures on either side of the joint will also be found intact. In ordinary transverse fractures, bony union is prevented by separation due to muscle contraction and the interposition of periosteum and torn capsule between the fragments, and also by tilting of the fragments, all three of which are hindrances to proper approximation, and one of which, the interposition of periosteum and torn capsule, forms an unsurmountable obstacle to bony union. The pathologic conditions, therefore, are absolutely in favor of operation. Treatment by apparatus is, moreover, unsatisfactory. There is a constant tendency to stretching of the fibrous structures causing weakness in the extension of the limb and inability to walk except on the level. Adhesions are apt to persist and cause pain, hence, the advisability of operative interference in all these cases. The amount of coincident traumatism and synovitis must determine the time of operation. If there is slight injury to the surrounding structures it may be immediate. If, however, the traumatism and synovitis are marked, it is best to allow a few days to elapse so as to give the system a chance to meet more effectively the additional traumatism of operation. This period varies from five to fourteen days. Over-separation of the fragments should be guarded against and effusion controlled by elevation, fixation, evaporating lotions, ice pack, etc. In case of extreme distension of the joint, aspiration may be performed aseptically. In his operations he makes it the rule not to allow the hand to touch the wound, using two knives, one for the skin and one for the deeper tissues, to protect against infection. The details of operation are given. The surfaces are freshened with a sharp curette, all the blood clots removed, the bone is drilled, the drill provided with an eye forming a carrier for the suture. He uses a medium-sized chromicized kangaroo tendon for suture. A light dressing is applied and the ends secured by the Volkman splint. In the later treatment he sometimes uses a light plaster cast if necessary. Cases are reported.

27 *Extensive Cavity Formation in the Central Nervous System, Presumably Due to Bacillus Aerogenes Capsulatus. Emma W. Mooers.
28 *Bacillus Shiga in an Epidemic of Diarrhea. Lawrence W. Strong.
29 *Systemic Infection Due to Natural Teeth Conditions. D. D. Smith.
30 *Suppuration of the Frontal, Ethmoid and Sphenoid Sinuses. (Concluded.) Edgar M. Holmes.

27. Cavity Formation in the Central Nervous System.—Mooers describes a case of very extensive "Gruyère cheese" brain and cord, of which the illustrations are very striking. The patient was an old paretic, profoundly demented. He died suddenly with signs of increased restlessness, abdominal distension, a temperature of 104 and respiration of 48 to 58. The autopsy showed the condition as mentioned and revealed in the cavities great numbers of bacilli about the size and appearance of anthrax bacilli, and morphologically and in staining reaction identical with the *Bacillus aerogenes capsulatus* of Welch. To these she attributes the cause of the condition and thinks it is probable that it existed before death as there was no other demonstrated cause and the invasion of the circulating blood by the bacilli might be assumed to account for the symptoms.

28. Bacillus Shiga in the Epidemic of Diarrhea.—Strong reports an epidemic of diarrhea, with many cases of ileocolitis in a seaside summer resort where sanitary conditions were almost ideal. The water supply seemed to be well isolated, there was nothing to credit it with the disorder. The milk supply was also apparently as good as could be expected. The bacillus isolated seemed to be identical with that of the *Bacillus dysenteriæ* of Shiga and its reaction in cultures was identical. The strongest suspicion as to cause of the disorder seems to have been from milk infection.

29.—This article has appeared elsewhere. See THE JOURNAL of March 14, ¶83, p. 739.

30. Sinus Suppuration.—Holmes' article is concluded in this issue. He notices the symptoms of nasal sinusitis at length, whether located in the anterior, ethmoid or sphenoid cells. Prognosis and treatment are also detailed. He thinks the prognosis is generally fair, though considerable care and attention should be given to the after-treatment, and some relics of the disorder may remain. The article with the preceding issues should be thoroughly read for its full understanding.

31 *Renal Decapsulation for Chronic Bright's Disease. George M. Edebohls.
32 *Specific Treatment of Diphtheria. George B. Philhower.
33 *The Psychical Element in Hay Fever. Raymond Wallace.
34 On the Biological Relationship of Proteids and on Proteid Assimilation. P. A. Levene.

31. Renal Decapsulation.—Edebohls reports his experience with his method of renal decapsulation for chronic Bright's disease, including a total of 51 cases. A number of these are reported in detail. There were 14 deaths; 7 of them within fifteen days of operation and 7 at later periods. Three of the 7 deaths of the operative mortality were due to uremia, 2 to acute dilatation of the heart, 1 was caused by pneumonia and one by combined uremia and cerebral hemiplegia. He was obliged to take cases almost moribund. He does not consider the mortality a serious one, in fact, the greatest peril to the patient is from the anesthetic. Of the remaining patients, 2 patients did not show satisfactory improvement; 22 are in various stages of satisfactory improvement and progress toward health at periods varying between two and fifteen months after operation. They have not, however, passed the probationary period of six months of normal urine, before the expiration of which no patient is entitled to a place on the list of cures. Nine patients were cured and remained cured in periods varying from one year, nine months to ten years. One patient operated on with one kidney had a repetition of chronic Bright's disease after four years. He thinks there are two important facts to be recognized, first, that chronic Bright's disease in its early stages, at least before serious and fatal damage has been done, is curable or susceptible to amelioration by renal decapsulation. The second is that renal decapsulation in the early stages of chronic Bright's disease is attended in competent hands with little or no risk of life.

32. Diphtheria.—Philhower advocates the use of antitoxin in all cases of diphtheria and would have it required by law. Since 1895 antitoxin has saved for him 28 children and given him just about one year's more sleep than he would otherwise have enjoyed without its use. He prefers to use in tonsillar cases 2,000 units, 10 c.c. in quantity. Nasal cases require two to three times as much and the laryngeal cases should receive from three to five times as much. If there is a great amount of glandular swelling, very large doses of 4 to 6,000 units should be used as the swelling indicates extensive poisoning. He prefers 2,000 units strength, in 10 c.c. and would stick to one reliable manufacturer.

33. **Hay Fever.**—The psychical element in this affection is noted by Wallace, who reports several cases where, he thinks, it was an important element. There is hardly another disease in which it is so important as in this.

37 Surgery of the Prostate, Pancreas, Diaphragm and Spleen. (Continued.) B. Merrill Ricketts.
38 A Combined Serum, Obtained from the Jackass and the Billy-goat. Brose S. Horne.

35. **Removal of the Appendix in Abdominal Operations.**—Baldwin has examined his cases for some time to see the condition of the appendix, and in a total of 636 he found it normal in only 27 cases. This, he thinks, is an overestimate, as external examination does not give a good idea of the internal conditions. He advises removal in all cases, and in nearly all of these the appendix was removed by his method of inversion, consisting in first ligating the meso-appendix close to the bowel, then cutting it across beyond the ligation and stripping it away from the appendix clear to the tip with the fingers or forceps. Then inverting the appendix commencing at the tip, and when concluded, a single stitch of catgut is taken across the inverted base and the operation is finished. The inverted appendix, he says, drops off in a few days and is evacuated. This takes one or two minutes of time, and he would not advise it in cases where great expedition is required on account of an alarming condition of the patient.

42. **Dementia Precox.**—Burr reviews the history of this form of mental disease remarking that hardly any of its symptoms are characteristic in its early stages, and that it is especially a disorder of bad organization. No one will get dementia precox except those who are preordained. He reports several cases to give the clinical picture of the disease and remarks that while the onset was said to be sudden, this is due to lack of careful observation in the preceding stages. Apart from heredity it is probable that a fetal disturbance may be largely its cause. The age of onset with marked symptoms varies within large limits. He includes here, rather provisionally, the original paranoia, reporting one case of this type The symptoms are nearly all mental. There may be emaciation, poor circulation, dermographia, etc., in the early stages, but there are never evidences of organic brain or spinal disease. There are no pathognomonic symptoms. The patient generally keeps his consciousness in the early stages of the disease, but can not control his hallucination or delirium. In stuporous cases unconsciousness may be apparent, not real, and during that stage there may be the increased muscle tension known as catatonia. Remissions are common. The prognosis is bad. The paranoid form is never recovered from. A few, 8 or 10 per cent., of the hebephrenics and a slightly larger number of the catatonics recover. Many go on to absolute dementia and some become quiet, chronic patients of the asylum. The treatment is not very hopeful in the well-pronounced disease, but careful attention to early training and environment may have very good results.

43. **Glossopharyngeus and Vagus Affections.**—Spiller reports a case in which there was an extensive softening involving the roots of the glossopharyngeus and vagus, and he remarks in regard to the functions of these nerves as indicated by the symptoms during life, especially the taste sensations. They were intact in the anterior portion of the tongue, hence, he concludes that they must pass through the chorda tympani, but whether through the portio intermedia or the trigeminus he is not prepared to say. As for the posterior portion of the tongue he is inclined to think that the glossopharyngeal nerve controls the function of that region. He also discusses the mode of innervation of the soft palate and the origin of the accessorius as illustrated by this case.

47. **The Skiagraph in Brain Lesions.**—From a number of cases here reported, McCarthy concludes that the value of the Roentgen rays in brain lesions is at present dubious, but it may yet be an important point in the diagnosis. To gain such experience no case should be allowed to escape the skiagrapher.

51 *The Etiology of Acne Vulgaris. T. Caspar Gilchrist.
52 Report of a Case of Systemic Blastomycosis, with Multiple Cutaneous and Subcutaneous Lesions. Oliver S. Ormsby.
53 Acne and Its Treatment. George H. Fox.

51. **Acne.**—Gilchrist has studied the etiology of acne vulgaris, including in this paper the results of his previous observations, and finds that a definite bacillus, which he had already named the *Bacillus acnes*, was present in all smears taken from 240 typical acne lesions in 85 patients. Pure cultures were obtained from 62 lesions in 29 patients. The others were failures largely because the proper media were not used. Others showed the *Staphylococcus pyogenes albus* or *epidermidis albus*. Sections of an excised comedo, of an early acne papule, of an acne pustule and of five acne nodules from 6 patients demonstrated the stages of the disease, consisting in changes extending deep into the corium surrounding in some nodules a magnified and markedly hypertrophied follicle. The lesion was made out of cell masses, many giant cells, plasma cells or connective tissue cells and many polymorphonuclear cells were present, massed in some sections so as to form miliary abscesses; numerous phagocytes and many pigment cells were also seen in some cases. The blood vessels were numerous and dilated. Some of the giant cells contained bacilli. *Bacillus acnes* was found pathogenic in mice and guinea-pigs. It is a short, thick bacillus in the smears, but in culture it often becomes much longer and thicker; and in old cultures assumes distinct branching forms. The clumping of *Bacillus acnes* by the sera of the patients affected with acne vulgaris suggests a specific toxic body derived from the presence of the bacilli and absorbed by the blood, resulting in a specific agglutination. Gilchrist thinks it is a question whether we are not taking a wrong view in considering the anemia, constipation, headache, coated tongue, etc., as always predisposing causes of acne vulgaris, whereas these may be the result of the absorption of toxins from the bacilli. He compares the disease with erysipelas. While there are predisposing causes such as age, diet, etc., there are many cases where all that is advised is carried out without results. In its severer forms acne vulgaris is a serious disease, not dangerous, but one that affects the whole system. He notices in conclusion Sabouraud's recent article and discovery of a microbacillus, which, he thinks, looks like his findings, but he remarks that it is curious that Sabouraud has observed no branching forms.

54 *Remarks on the Significance of Some Nervous Signs and Symptoms. Charles G. Chaddock.
55 *Tobacco Poisoning. A. C. H. Friedmann.
56 Laboratory Diagnosis—Its Relation to the General Practitioner. Raymond Wallace.
57 Appendicitis. H. L. Nietert.

54. **Significance of Nervous Reflexes.**—From his observations, and he criticises the text-books, Chaddock deduces that alterations, that is, exaggeration or diminution of the deep reflexes are almost always indicative of organic nervous disease; that the Babinski sign (the physiologic presence in infancy excepted) and foot-clonus are always signs of organic nervous disease, and lastly, anomalies of pupillary reaction to light have the same significance. There is only one exception to these deductions: disease of a joint may cause atrophy of muscles about it and with this, exaggeration of related deep reflexes. He doubts the pathologic exaggeration or diminution of deep reflexes during fatigue.

55. **Tobacco Poisoning.**—Friedmann thinks that the smoking of tobacco is especially injurious if excessive, as also is tobacco chewing, which may give rise to tobacco psychoses. Snuff-taking does not affect the general health, but may injure the middle-ear and set up a distinct form of chronic otitis media. The relation of alcohol to tobacco as a cause of amblyopia is discussed, but he thinks the effects of alcohol on the eyes are decidedly different, and as a rule not half as serious. The great danger of this is in the general poisoning of the nervous system and there is no such demoralizing effect after tobacco use. The danger, of course, lies in the fact that both are usually practiced by the same individual and he has to combat them both together.

65 *The Presence of the Shiga Variety of Dysentery Bacilli in an Extensive Epidemic of Dysentery, with Notes upon the Serum Reactions Obtained. Wm. H. Park and H. W. Carey.

58. **The Morphology of Bacillus Diphtheriae.**—Denny has investigated this bacillus and its allied forms, and finds that the three forms, the *Bacillus diphtheriæ*, the *Bacillus pseudo-diphtheriæ* and the *Bacillus xerosis* are similar in young cultures. In older cultures differences are seen. The *Bacillus diphtheriæ* has a more marked development as a higher form, showing clubbed, barred and filamentous forms, and occasionally true branching. The *Bacillus pseudo-diphtheriæ* has no such development, but the *Bacillus xerosis* has a higher development, characterized by the elongation of the rods and the breaking up of the protoplasm into segments. He suggests that the diphtheria bacillus and that of xerosis have developed by evolution from simple forms like *Bacillus pseudo-diphtheriæ*, each passing through, in its early life, a stage of development corresponding to the early development of the race, or it is possible that the *Bacillus pseudo-diphtheriæ* represents a reversion from a higher type.

65. **Dysentery Bacilli.**—Park and Carey describe an epidemic of dysentery occurring in a town of about 3,000 population, a little north of New York City. There were about 350 cases with a mortality of 6 per cent., the average age of fatal cases being a little less than three years. The epidemic was most severe among the class of people living in filthy surroundings. There was no sewage system and the well water was badly contaminated. The onset in all cases was sudden, with cramps, diarrhea and tenesmus. The stools were at first feculent, then sero-mucous, then finally bloody and mucous. Blood was present in considerable quantity for two or three days and then disappeared. It disappeared entirely in most cases in six to ten days. Temperatures were low. The mild cases lasted generally two weeks, the severe three to four, the malignant a few days. In one fatal case of a child aged one year and four months, an autopsy was obtained and the Shiga bacillus isolated. Dysentery-like bacilli were also found in the feces of several convalescents. The difference was in the indol formation and the manit fermentation, also in their agglutination reaction. The authors hold that there may be more than one form of bacillus responsible for dysentery epidemics. It is extremely probable that if Shiga carries out his culture and agglutination tests as far as is now known to be necessary in order to differentiate the varieties, it will be found that in Japan, as well as in America and elsewhere, not one, but several varieties of this group of bacilli are present.

67 *The Conservation of Binocular Single Vision. Eugene R. Lewis.
68 *Paraffin—Its Use in the Formation of a Stump After an Enucleation. George F. Suker.
69 *An Examination, Personally Conducted, of 4,608 Railroad Employes for Acuity of Vision, Hearing and Color Perception. Gilbert D. Murray.

67. **Lack of Binocular Single Vision.**—This condition is much more common than is usually supposed, according to Lewis' observations. He summarizes his conclusions on the subject in the following: "1. The only congenital attribute of vision is proper light perception. All other visual attributes depend on learning on the part of the child. 2. In many cases certain influences cause this learning to be directed into other than normal paths, in which event the act of binocular single vision is not learned. 3. Lack of binocular single vision is a very prevalent condition. 4. This lack represents great loss to the individual. 5. Cases in which the causal influences can be removed may be differentiated from those in which such removal is impossible. 6. Proper measures adopted at the right time will result in conservation of binocular single vision in a large number of cases."

68. **Paraffin for Eye Stumps After Enucleation.**—Paraffin prothesis for making a stump is recommended by Suker, who uses a mixture of white paraffin and pure vaselin, 3/5 of the latter and 2/5 of the former. This gives a mixture which melts at 102 F. Later the vaselin is absorbed, leaving the hard paraffin, with a higher melting point. This has been proven in cases of furnace workers. The melting point of paraffin can be regulated by the amount of vaselin added; the more vaselin the lower the melting point, and vice versa. He would preferably inject the paraffin about one week after evisceration. It is still more useful for restoration of a sunken socket after a remote enucleation. The details of the procedure are given:

> After thoroughly cocainizing the socket, as well as having freely used adrenalin (1/1000), with a pair of tissue forceps you pick up the apex of the socket-pit: then with a narrow scalpel you enter the subconjunctival space at the apex to the extent of 3 millimeters, then make an elliptical cut about the point of entrance. This will give you a pocket in both culs-de-sac, with but a single opening. The entire anterior flap of this pocket will be approximately 3 mm. thick, and the size of the pocket will be in accordance with the size of the socket to be filled out. The higher you cut into the cul-de-sac, the more prominent will the stump be after the injection of the paraffin. After checking the trivial hemorrhage, you inject about a dram or so of properly prepared paraffin through this small opening, or enough to give you the desired fulness. However, be careful not to overdistend the cavity as this will produce not only great pain but even sloughing of the flap with the ultimate expulsion of the paraffin. Before introducing the paraffin it is advisable to place a suture so as to be able to close the opening after the injection, it being rather difficult to do it afterward.

The reaction is usually quite severe, but can be controlled by a cold pack for several hours and repeated as needed. The artificial shell can generally be inserted in one week to ten days later.

69. **Railroad Employes' Examinations.**—Murray reports the results of examination of something over 4,000 men for the Delaware, Lackawanna & Western Railroad for vision, hearing and color perception. He found about 3.01 per cent. were color blind; 2.58 per cent. had weak chromatic sense; 9.44 per cent. were in need of glasses or other means to improve their vision for distance. He suggests discouraging the use of tobacco and making frequent examinations on account of the dangers of acquired color blindness; that the employes should have at least eight hours of sleep, as loss of sleep leads to intemperance, smoking and nervous irritability.

75 A Review of Some of the Older Writings on Maternal Nursing. Samuel McC. Hamill.
76 *Celiotomy During Pregnancy. J. H. Carstens.

70. **Rupture of the Uterus.**—De Lee reports a case and reviews the treatment. He remarks that it is not always possible or advisable to attempt to deliver a child by the natural route on account of the danger of hemorrhage. In case of uncontrollable hemorrhage or highly contracted pelvis, laparotomy may be imperative. What to do with the uterus depends on the conditions. In hospitals and under aseptic treatment the uterus may be closed with a suture or drained from below, but if there is any suspicion of sepsis, the whole uterus should be removed, the peritoneum closed and the subperitoneal space drained per vaginam. It is an accident which usually occurs at home and has to be treated where it occurs. The conditions do not permit of transportation, as a rule, and since laparotomy is a formidable operation requiring much preparation, the method of treatment that brings about the quickest delivery, stops hemorrhage and gets the patient into bed is the correct one. Of the four methods of treatment, delivering the patient from below, that is, expectancy and symptomatic treatment, tamponade, with or without suture, or extirpation of the uterus per vaginam, the best one is the partial suture and drainage of the peritoneal cavity and site of rupture. In septic cases drainage offers much hope, but vaginal extirpation of the uterus is coming into vogue and when hemorrhage is not too severe it may be practiced.

72. **Uterine and Gastric Diseases.**—The relation of uterine and gastric diseases are summarized by Oedö as follows:

1. Uterine and gastric troubles may be in close reciprocal relation. 2. In making a diagnosis of reciprocal action, merely coincident affections of these organs must be strictly excluded. 3. The first medium of reciprocal action is the nerve path, the center of which for the genital is to be sought, not in the brain or spinal cord, but in the sympathetic system. The ventral center of this is the solar ganglion, by means of which the uterus, through the inferior hypogastric plexus, is brought into reflex association with the anterior and posterior gastric plexuses. The reflex paths are called spermatic, pudendo-hemorrhoidal, cutaneo-cavernous, utero-celiac, and utero-spinal anastomoses. The more direct reflex paths are direct connections of the vagus with the sympathetic nerve system without entering the solar plexus, especially with the utero-vaginal plexus and with the parauterine ganglia, which are connected with this (genito-orural anastomosis). 4. The other mode of origin of reciprocal action must be sought in changes of the common statical relations of both organs. 5. Dislocations of the stomach cause uterine displacement through reciprocal action of the statical mechanical forces (secondary uterine trouble); whereas primary displacements of the uterus produce secondary gastroneurosis or actual gastric disease, the reciprocal action in these cases being brought about through nerve reflexes. 6. The blood path plays a rôle of only tertiary rank in regard to this reciprocal action.

73. **Puerperal Eclampsia.**—The theories of eclampsia are noticed by Partridge, who considers the albuminuric theory insufficient. The thyroid theory may be correct in some cases, but the most generally accepted one, and the one that best explains the condition, is the toxemic or metabolic theory, and he is inclined to follow Dorland's suggestion that acetone may be responsible, though other toxic agents also have an action, and there is a promising field of researeh here. He considers that in treatment, chloroform, while it controls the attacks, is only treating a symptom. Morphia dries up the secretions, though this objection is often more theoretical than practical. Venesection and veratrum viride are mentioned as of use in certain cases, and pilocarpin is occasionally of much value, though it is liable to produce edema of the lungs, a danger to which the patient is already only too subject. Chloral and the bromids are the sheet anchors as far as controlling convulsions are concerned. They should be preferably given by the rectum. Diuretics and cathartics should be given in every case until both the kidneys and the bowels are thoroughly active. For bowel action croton oil or saline cathartics are preferable. Hot baths, hot packs or hot air are of value, and one or the other should be used in every case to produce sweating. When the temperature is rising, a cold tub bath may do good, as in one case reported. The use of normal saline solution is becoming more and more popular, and deservedly so. The last and most important method of all is emptying the uterus. The method of procedure must vary with the case, using the dilator if necessary. Undue force and too great haste must be avoided, however.

81 Observations upon the Hypnotic Action of Hedonal. Frederick L. Hills.
82 *An Inquiry into the Value of the Irrigation Method as a Means of Aborting and Treating Acute Specific Urethritis. Orville Horwitz.

78. **Smoke Inhalation.**—The danger of inhaling smoke, according to Da Costa, is very serious. There is a great difference among men in their tolerance of it, alcoholic cases and fat people with heart disease can not stand much. There is a great difference also in the various kinds of smoke. In all cases it contains some carbon monoxid. Some smoke is merely irrespirable, some is not only irrespirable, but poisonous and irritating. Cold smoke is much less troublesome than hot smoke. Among the worst forms of plain smoke may be mentioned smoke from lumber, furniture, barrel-staves, peach baskets and paper, which is suffocating and irritating to the eyes and respiratory organs. Smoke from oil, varnish or paint is hard to tolerate, while that of rags, hay, pitch and petroleum is not so offensive or so irritating. The density must be taken into account. Comparatively innocent smoke if very dense will be equally bad. The theory that smoke is only irrespirable when a lamp will not burn in it is not correct, as a lamp will burn in smoke that a man can not breathe. Smoke containing ammonia or sulphuric acid is especially bad. Illuminating gas is very dangerous, especially water gas which is at present so much used and can not be detected by its odor. Smoke containing acid fumes is very bad, as shown by the recent experience at Milwaukee where the chief of the fire department and three of his men died from the inhalation of nitric acid fumes. A man generally knows when he is going to be overcome, by the tendency to breathe with his mouth open, to take deeper and more frequent breaths, and by the development of singing in the ears, oppression in the chest, etc. He often falls when he gets out into the fresh air, but ordinarily recovers, though he is more likely to be overcome the second time. In very severe cases consciousness may be lost, the extremities become cold, muscles relaxed and delirium may follow the unconsciousness. The milder cases recover in the open air. In the actual cases of unconsciousness there is danger. Firemen believe in yeast beer as a remedy which causes a gaseous distension of the stomach, with belching and sometimes vomiting. Dr. Da Costa is not able to show how this benefits, but they have great faith in it. In treatment, artificial respiration, the administration of oxygen, rubbing the extremities and later hot applications and further symptomatic treatment. The surgeon should always ask whether the smoke is clean smoke or not, in treating these cases. The victims of "back drafts" are usually scorched and shocked. Men who inhale hot smoke should be given stimulants at once and removed to a hospital. The coal gas effects are especially bad, and a man will generally have warning of it in headache and great muscle weakness before he is overcome. In these cases when a man is overcome with illuminating gas, artificial respiration should be practiced and continued until satisfactory results have been obtained; rubbing the extremities, a mustard plaster over the heart, hypodermic injections of strychnin or atropin and as soon as safe to move the patient, he should be taken to a hospital. In cases of inhaled ammonia the inhalation of vinegar is advisable, and very

dilute ammonia may be given after the inhalation of acid vapors. Vomiting should be encouraged. If chlorin or hydrochloric acid has been inhaled, the best treatment is the inhalation of steam. If these have been inhaled to any great extent, the man's life is in danger from glottic edema and an immediate tracheotomy may be required.

80. **Tuberculin.**—The literature is first noticed by Pottenger, who deduces, in substance, the following conclusions from the answers received in his investigation: I. The profession, especially in Europe, is becoming less hostile to tuberculin and its allied products. The greatest opposition is from those who were unfortunate in their first experience. All who have used it later in suitable cases have observed a benefit, and those who have studied the remedies most carefully and used the greatest care and judgment in the selection of cases, have found almost without exception that they are of value. In 1,200 first stage cases, 610 treated in sanatoria by the usual hygienic methods and 589 under the same careful management plus tuberculin, 20.2 per cent. more of the latter were cured than of the former. Tuberculin checks the tendency of the disease to spread to new tissue, and there is less danger of relapse. He therefore concludes that tuberculin and the allied products are therapeutic measures in tuberculosis that are worth our earnest attention.

83 Report of a Case of Intestinal Anastomosis Following Strangulated Inguinal Hernia. C. Lester Hall.
84 Acute Appendicitis and Its Treatment. (To be continued.) John B. Deaver.
85 *Some Clinical and Operative Phases of Appendicitis. A. H. Cordier.
86 *Apomorphia and Some of Its Uses. W. H. Middleton.

85. **Appendicitis.**—Cordier advocates operation in nearly all cases. The clinical history is often misleading. The temperature is not so very important as an operation indicator as has been held. The pulse is, as a rule, increased, and can be relied on more in prognosis than can the temperature. This is especially true in the later stages of general peritonitis, but as long as the trouble is confined to the appendix proper, or its immediate vicinity, its behavior is often misleading. There may be a pulse of 140 from ptomaine absorption without any peritonitis at all, and this is often lost sight of by the practitioner. The rapidly constitutional septic cases are the most fatal of all. Pain is always present at some stage, yet its character and intensity is as variable as any other symptom. To rely on it would often be disastrous. He thinks the McBurney point is the most unfortunate discovery ever made. The appendix points according to its location, length and to the location of the pathology of the organ, and dependence on this point will lead to error. The most trustworthy indication of the true condition is, he thinks, tenderness located at the point nearest the site of that portion of the appendix diseased. Intestinal gaseous distension as a symptom of danger is valuable, but its absence is often misleading. The main point in his paper is to lay stress on the fact that to expect to find typical smyptoms and be governed by their presence or absence, is a mistake and will cause delays and fatal errors. The presence or absence of leucocytosis is also too uncertain and misleading to be taken seriously.

86. **Apomorphia.**—The value of apomorphia in various conditions is insisted on by Middleton, who finds it one of the best emetics, acting directly on the vomiting center and producing but little nausea and usually no depression. He has seen it act in one or two minutes. While it is generally considered harmless, idiosyncrasy should be regarded. Death has occurred from the hypodermic injection of 1/15 of a grain. When necessary to evacuate the stomach no remedy acts so well. It has no irritating effect on the mucosa. Some authors say that the emetic action of apomorphia is hindered by chloroform or chloral and intensified by morphin. If this is so, it would seem that the drug is especially adapted to cases of morphin narcosis. Nothing arrests the hysterical paroxysms so quickly. He often gives it for various purposes in non-emetic doses, and in combination with codein and white pine mixture it forms an ideal cough mixture, and it has no rival in post-grippal cough. As an expectorant, it takes a prominent position and in croup it has given him splendid results.

90 A New Method of Treatment for Chronic Anterior Urethritis and for the Declining Stage of Acute Urethritis. William W. Townsend.

88. **Family History in Tuberculosis.**—The modern tendency to attribute everything to germs and neglect heredity is opposed by Bisbee in the case of tuberculosis. He thinks importance should be laid on a number of conditions, especially by life insurance examiners. Contagion is only one; age, occupation, habits, personal history, weight and especially the family history are insisted on. The points, he says, on which we should lay strong emphasis are that there is nothing in the modern doctrine of tuberculosis or any recorded experience of life insurance companies justifying the conclusion that a consumptive family history can be neglected; that, while the death of a parent, or brother, or sister from consumption increases the liability to disease, it is possible to get a proper understanding of the degree of impairment only by giving attention to the applicant himself, his environments and his personal health record, as well as his family history. There should be no fixed rules. An active outdoor life, temperate habits and a robust physique may be looked on as compensating features when there is an inherited tubercular tendency, while the opposite conditions affect the risk adversely.

95 *Observations on the Micro-organisms in the Water of Public Swimming Baths, and a Suggestion. E. E. Glynn.

95. **Micro-organisms in Public Baths.**—Glynn has investigated the water of various Liverpool swimming baths at different periods of the day and finds a vast increase in the number of bacteria towards the close of the day. He describes his methods, which seem to be satisfactory; taking an average of five observations on separate days of first class baths, it was found that the number of bacteria per c.c. in the water at night was 4,676; deducting 200 for those already present in the bath and 400 for multiplication, we find that 292 bathers introduced in round numbers 4,000 bacteria per c.c. Therefore, each individual introduced 13.7 bacteria per c.c. The water removed from the skin and hair of each bather in about ten minutes, approximately gave 4,000,000 germs. He says it is a great and glorious thing to wash, even in a swimming bath and without soap. In the second-class bath each bather contaminated the water with 6,000,000,000 bacteria. They are mainly small boys, which implies that the skin of the small boy in the second class is at least twice as dirty as that of the more respectable bathers in the first class. One has only to see the small boy before and after bathing to be convinced of this fact. He describes the methods in which the contamination takes place, and suggests an ideal bath where this might be avoided. The bacteria that were found were mostly the white staphylococci, and colon bacillus at the end of the day. He thinks the feeling of stupor and fatigue after swimming in a public bath, as felt by some persons, is not due to the numerous microbes contained in the water, but to defective ventilation.

5 *The Morbid Anatomy of Erythromelalgia Based upon the Examination of the Amputated Extremities of Three Cases. H. Batty Shaw.
6 Prevaccinated Smallpox. J. Duncan Howe.
7 *Note on the Detection of Raw Milk and Formaldehyd. J. E. Saul.

1. **Immunity.**—This first lecture by Grunbaum gives the theories of immunity and a detailed description of Ehrlich's theory with schematic illustrations, showing the different active elements assumed to exist by the theory. The article requires close reading for a proper understanding of it.

5. **Erythromelalgia.**—In three cases of such severity that amputation had to be performed the feet were carefully studied by Shaw, who finds that the changes in the nerves described by some writers were not present, but there were decided vascular changes, which were present in all. These were mostly an increase in the intima of the arteries, and occasionally thrombosis and changes in the inner coat of the veins. There was no nerve degeneration or any suggestion of increased fibrous tissue in the nerve trunks. He thinks, from a consideration of the reported cases that it would appear that erythromelalgia when occurring independently of central nervous change is associated with but one morbid picture, that of local vascular change.

7. **Raw Milk and Formaldehyd.**—Saul reports an interesting reaction of raw milk, which he thinks may be practically useful. On treating milk with a solution of orthomethylaminophenol sulphate and then adding a hydrogen peroxid solution a very vivid red color is produced. Milk that has been previously boiled and cooled remains uncolored, a faint pink only developing on standing. The red color is so marked that as little as 1 per cent. of raw milk if added to heated milk can be detected at ease. A convenient way to apply this is as follows: To 9 or 10 c.cm. of the milk add 1 c.cm. of a recently prepared 1 per cent. aqueous solution of orthomethylaminophenol sulphate and then one drop of commercial hydrogen peroxid solution (about 3 per cent.). The red color develops within 30 seconds if there is any raw milk present in the

sample. There should be no excess of hydrógen peroxid, as it tends to weaken the color. Dilute acids do not affect, caustic alkali destroys the color. The presence in the milk of boric acid, borax, formaldehyd, or sodium carbonate or bicarbonate does not interfere with the reaction. If the milk has become sour, the acid should be neutralized. The temperature was noted at which the active agent in the reaction was destroyed. The milk maintained at 70 C. for one hour reacted readily, but if kept at 75 C. for half an hour, it failed to give the color. It would appear that milk loses its power to react at about the temperature at which enzymes are destroyed. It may be difficult to get the aminophenol derivative above mentioned. He thinks it might be convenient to use the photographic developing agent sold under the name of "ortol," which appears to be a mixture of orthomethylaminophenol sulphate with quinol. The latter body may be removed from it by extraction with ether, but the presence of a small quantity would not interfere with the test, and might even slightly assist it. On adding nine or ten volumes of milk to a 1 per cent. solution of the salt and allowing the mixture to stand, a pink color is gradually produced in the presence of formaldehyd. The reaction is distinct where the milk contains a 1 per cent. solution in 100,000 of formaldehyd or more. The time necessary for the reaction varies with the temperature. It is really an acceleration of the development of a color which ultimately is produced in milk free from formaldehyd. This and the fact that formaldehyd shares the property with other aldehydes and ketones seriously diminishes its value as a test. One, therefore, can not compare it with the modified sulphuric acid reaction of Hebner or the recent "amidol" test of Manget and Marion.

15 Diabetic Gangrene of the Toe; Amputation of the Toe; Recovery. Charles Fisher.

9. **The Appendix.**—The Hunterian lectures, the first two of which appeared in the "Lancet," March 14, describe the anatomy of the organ, the characters of the normal appendix and the theories of its physiology. Eccles thinks that probably the real function is in part absorptive and in part excretive. In the second lecture the etiology of the inflammation is discussed and he believes that every case of so-called appendicular colic, slight appendicitis, etc., is in truth an actual inflammation of the appendix of bacterial origin. He finds from many authorities that the colon bacillus is the most common infecting agent, 94 per cent., tubercle bacillus 2 per cent., staphylococci and streptococci each 1.5 per cent., and in still lesser proportions the pyocyaneus and prodigiosus. Tuberculosis of the appendix may be only a part of a general infection. Its secondary occurrence is by no means rare. He holds that calculi and concretions are always formed within the lumen. Actinomycosis may occur. One effect of the inflammation is obliteration of the lumen of the appendix, and this may produce a spontaneous cure and is a normal tendency in later life. In order to bring about immunity to a recurrent appendicitis the whole of the lumen should be obliterated. This is not by any means always the case. Secondary abscesses may be due to leaving behind some foci of infection and may occur after complete removal of the organ. The anemia in the appendicitis patient is, he thinks, due to the same cause as the appendicitis, a disordered state of the alimentary tract. He thinks leucocytosis has a certain value in the diagnosis.

In this third lecture, the association of appendicitis with joint lesions and the complications of pregnancy and parturition are first noted. Its association with the latter condition is by no means uncommon and is of very serious import. The diagnosis is seriously embarrassed in the later months of pregnancy and the history of a previous attack is of the greatest assistance here. Miscarriage or premature labor is almost certain to occur and this brings about a danger to both mother and child. The wisest course, he thinks, is to operate on all cases or those suspected cases in pregnancy at the earliest possible moment, disregarding the fact of the gravid uterus. He does not see any use in artificial emptying the uterus before operation. The somewhat difficult question as to the relation of appendicitis to life insurance is discussed briefly. New growths are described. These are more commonly malignant than innocent, though neither are frequent. Secondary neoplasms are not so rare. The question arises whether previous attacks of inflammation predispose to their occurrence, but the records are deficient as regards this point. While there is scanty evidence of appendicular calculi being a predisposing cause of carcinoma, as biliary calculi are supposed to be, there is something in favor of the theory that previous attacks of appendicitis may have their influence. Hernia of the appendix is discussed at some length. It is probably connected with elongation. Adhesions are common and inflammation of the appendix in the hernial sac is decidedly common. Usually on opening the sac the appendix is readily recognized, but at times, owing to adhesions which are very common and locking together of tissues, it is difficult to be sure what structure is being dealt with. If operation for a radical cure of a non-strangulated irreducible hernia is undertaken and the appendix found in the sac it may be returned to the abdomen or amputated in the usual manner and the stump returned, which is a better plan. If the tube is found adherent, and especially if not of natural size, it is well to free it from its attachments and to remove as much as can be readily drawn down into the sac.

10. **Skin Inflammations.**—This third lecture by Crocker treats of the action of arsenic, which has its inconveniences in producing pigmentation and even keratosis, but it is valuable in many conditions, among which he enumerates certain forms of angioneuroses, recurring sweat eruptions, pemphigus, dermatitis herpetiformis, etc. He thinks its indiscriminate use, however, makes it more important to point out where it is useless. He sees no good of it in discharging eczemas or wherever there is gastric irritation. He prefers in giving it in liquid form, such as Fowler's solution. Salicin and the salicylates have their value in many conditions and are most likely to be successful in cases of microbic origin, such as psoriasis, lichen planus, pityriasis rosea. In psoriasis the salicylate should be given in dilute doses of 15 gr. three times a day, then increased to 20 or 30 grains, though hardly ever so much as the latter is required. In the majority of cases its action is quicker and it is more successful than arsenic. In some cases of lichen planus it is of use. He thinks it is likely that some drugs breaking up in the organism, like aspirin, may have some similar effects. Thyroid extract has not met expectations, but he has found it decidedly useful in some cases of psoriasis and in Willan's and Hebra's prurigo, eczema on a congenitally ichthyotic skin and lichen acuminatus and has found it more valuable in lupus vulgaris than any internal medication he has given. Ichthyol is sometimes beneficial in hyperemic diseases like acne and in some sweat eruptions. In extensive dermatitis there is no drug he has a higher opinion of than quinin in good-sized doses of 5 to 10 gr. and in an effervescing citrate of potassium mixture. He remarks in regard to subcutaneous and intermuscular injections and says there are certain measures that ought to be adopted in all cases of widespread skin inflammation. These are rest, equability of temperature; sudden changes of temperature are bad in certain cases. For local treatment he thinks we should have a definite aim. Is it the hyperemia that is to be subdued, the exudation to be dried up or the suppuration to be stopped, or is it some microparasite that is to be destroyed without increasing the inflammation? Regard should be paid to idiosyncrasy, and he gives, in conclusion, some general deductions: That a large proportion of skin inflammations is of mixed origin, frequently a microbic element exists, and some microbes may pro-

duce different forms, according to the mode of attack. It requires a suitable soil, which varies with the age of the individual and the character of the skin. Intestinal and other visceral toxins and ptomaines play an important and often unsuspected part, acting through the vasomotor nerves rather than directly through the skin. The cerebral nervous system acts chiefly as a control influence over the sympathetic system as regards the intensity of the eruption, but, with few exceptions, the nervous system, whether vasomotor or cerebral, has but little influence on the character of the eruption, though it does on its distribution and intensity. The character of the eruption is mainly due to individual peculiarities or proclivities not always explainable. Many general eruptions are for a short or long time of local origin, occupying only a small area, therefore early treatment is desirable. The principles of treatment depend mainly on an appreciation of the relative importance in any one case of the microbic, the personal, the nervous and the toxic elements. The most reliable and comprehensive specifics are arsenic, salicin, thyroid extract, quinin in large doses and iodid of potassium. The first two have a wide range. Except as regards pus eruptions and those demonstrably of micro-parasitic origin the character of the local treatment depends comparatively little on the diagnosis of the particular kind of dermatitis, the extent, intensity and localization being the most important elements. The microbicide should be non-irritating, or should at least be capable of being at once neutralized, otherwise it may set up more inflammation than it controls. It is in comparatively few circumscribed microbic diseases, such as impetigo contagiosa, boils and carbuncles, that the microbicide is the sole curative agent. In all widespread forms of dermatitis rest and equability of temperature are most important and often the essential curative agents. Finally, as we study diseases of the skin as we do those of other organs, we will find that their treatment can be carried out best on the sound basis of pathology and that species will have a diminishing importance.

12. **The Height of the Diaphragm.**—Andrew has studied the height of the diaphragm in nine cases, and finds a wide variation which is well marked in female subjects. In two females the height of the dome in the right mammary line varied from the fourth rib to the sixth interspace, whereas in the two males it did not extend down lower than the fifth rib. Secondly, it is remarkable that so many abnormalities in the position of the viscera should have existed in such a small number of cases and chiefly in females. In the 7 cases examined there were 2 distinct and 2 indistinct cases of Riedel's lobe of the liver; 2 affections of the gall bladder and 1 gastric abnormality. The measurements of the recti muscles as an indication of the strength of the abdominal muscles are interesting. In every case they were smaller in the females than in the males and especially where Reidel's lobe was present. The distance of the great curvature of the stomach and the transverse colon below the xiphoid cartilage was also greater in the females than in the males.

17. **Floating Pseudo-Arthrosis of the Hip.**—A child sometimes presents the appearance and gait of congenital luxation of the hip joint, but palpation shows that there is no trace of a neck to the femur and it feels as if it had been decapitated. Radiography confirms this absence of the neck and also of the upper epiphysis of the femur. A scar is also found and the parents relate that in early infancy the child had a period of fever and restlessness terminated by the development of an abscess in the hip which opened spontaneously or had to be incised. As soon as it was evacuated the child appeared restored to normal health. The rapid recovery excludes the idea of tuberculosis. In one of the 4 cases described the mother had an abscess at the time and in another a vaccination pustule had become secondarily infected. In one of the cases abscesses developed simultaneously in several joints. The prognosis of this floating pseudo-arthrosis is very grave. There is no ankylosis and no tendency to the formation of a socket in the ilium owing to the absence of the neck and otherwise defective development of the head of the femur. One of the cases was treated on the mistaken diagnosis of congenital luxation, with the inevitable result of total failure of all attempts at reduction. The only treatment is the appliance devised for inoperable congenital luxation on the principle of Dupuytren's girdle. In taking the cast a socket for the top of the femur must be made in it and in the appliance, to hold the head of the femur down. Another important point is to hold the shoulder and pelvis at the proper distance apart. This is accomplished by having the corset reach to the axilla and making it a little higher on this side than on the other.

19. **Staples for Fractures.**—The agrafes described are of metal and resemble a broad U in shape or a letter E without the central projection. The shanks are pointed, with 4 projecting flanges so as to afford a strong hold in the bone. The secret of success in applying them in a case of fracture is to have the agrafe perpendicular to the line of the fracture. This prevents any pivoting on one shank and consequent displacement of the stumps. (See pp. 892-894, THE JOURNAL, April 4.)

20. **Newspapers and Fraudulent Advertisements.**—De Lavarenne comments on the way in which newspapers are penetrating to the remotest hamlets and the avidity with which they are devoured. Especially in country towns and villages the daily or weekly paper is read from beginning to end and the advertisements of nostrums, the seductive descriptions of the infallible cures and suggestion of symptoms have great influence over the reading public. Why apply to a physician and pay his fee and pay for his medicine when here is just the remedy the reader wants, the price is known beforehand, and a guarantee to cure is given? It is much cheaper and simpler to buy a bottle of the advertised nostrum. This evil is constantly assuming larger and larger dimensions in France, as elsewhere, with the colossal development of the daily press and the means of advertisement it offers. De Lavarenne hails with delight the recent legal decision at Breslau already mentioned in these columns in which an advertiser who promised to cure all cases of stuttering, under written guarantee, was fined and further advertising of such claims prohibited. The physicians who instituted the suit testified that in the present state of medical science it was impossible to cure, much less guarantee a cure every time. The suit was brought in the civil court, as a damage suit, not as usual in procedures against charlatans in the criminal court for illegal practice of medicine. He urges physicians in France to follow the example of their German confrères.

22. **Treatment of Phlebalgia by Effleurage of the Veins.**—Neuropathics and varicose subjects, as also those convalescing from phlebitis, are liable to suffer from "venous neuralgia," and

the best treatment is by light massage or effleurage. The strokes should be upward, and if very painful, they should be done in the bath. This treatment should not be instituted until after all inflammatory manifestations have long subsided. The hand is oiled with vaselin and under the light manipulations the part grows warm while the pain subsides. The pain is liable to recur after four or five hours, but repetition of the effleurage the next and following days will favor the resolution of the inflammatory exudate which causes the pain. Baths in case of phlebalgia should not cause a sensation of either heat or cold; the neutral temperature is peculiarly soothing. The effleurage prevents congestion and thus obviates recurrence of the phlebitis. The patient can apply it himself in time at the slightest intimation of congestion or pain and thus ward off recurrences or prevent phlebitis.

23. **Pathogenic Action of Radium.**—Danysz reported at the Paris Académie des Sciences that the radium rays have an intense action on the skin but that the underlying tissues were very little affected by them in his tests on animals. He, therefore, ascribes their action to the susceptibility of the nerves in the skin. The solutions of radium salts produced the same effect as the metal in tests on certain of the lower animals. Caterpillars became paralyzed and died when exposed to their radiations and the development of the anthrax bacillus was checked.

30. **Practical Application of Cryoscopy of Milk.**—Parmentier remarks that of the 350 millions of quarts of milk consumed annually at Paris, nearly 5 millions are taken by the hospitals and public charities. The purity of milk is, therefore, a peculiarly important question for the members of the profession connected with the hospitals. He has been making a very extensive study of the practical application of cryoscopy as a means of detecting adulteration and has become convinced that it is a simple, practical and reliable means of testing the quality of the milk. He has found that the freezing-point of milk is a constant figure, .55 to .56 C., whether Pasteurized or not, and milk with this freezing-point when drawn from the cow should have the same when delivered to the consumer. If the freezing-point is .52 the milk has been manipulated somewhere. The age, breed, food, etc., of the cow do not affect the freezing-point in normal milk, but it varies in case of disease in the animal or merely with a local inflammatory process. The freezing-point of both cream and skim-milk is the same, consequently cryoscopy does not reveal fraud in this respect, but it invariably indicates if the milk has been watered, and is the most exact and rapid method of determining this yet discovered. If the milk were adulterated with water containing just the right proportion of salts to keep the freezing-point at the right spot—which would be a difficult matter—the fraud then would be revealed by the taste, or by simple chemical tests. The research described was made with the ordinary technic of cryoscopy, not using an instrument of precision, as the aim was to bring this simple method of testing milk within the reach of every practitioner.

35. **Congenital Strictures of the Urethra.**—Bazy gives illustrations of the conditions observed in certain strictures of the urethra and a diagrammatic representation of the way in which they are probably formed. There are evidently some congenital bands or valves in the bulbar portion of the urethra which form the stricture. They are relics of the uro-genital membrane of embryonal existence. As in the rectum and elsewhere, the stricture may therefore be congenital, pathologic or traumatic.

36. **Medical Impressions of the Museums of Italy.**—Twenty fine photogravures illustrate this article, reproducing some of the famous paintings which portray medical or surgical scenes, the birth of Eve, the Circumcision, hospitals, miracles, etc. A preliminary sketch made by Raphael for his famous "Transfiguration" shows that he drew all the figures nude to study the muscular action before draping them in the finished picture. The group in the foreground is a mother and father bringing their son, "possessed of a devil," to be healed. The disciples, by gestures, express their inability to help her and point to the transfigured Lord above while the father supports the youth in the throes of an attack of convulsions. Another interesting picture from a medical point of view is "La Gravida," at Florence, one of Raphael's earlier works. In his great painting of the "Visitation," lifesize, at Madrid, the Virgin is also represented in an advanced stage of pregnancy. A work by Lorenzetti at Pisa portrays "The Triumph of Death." Three coffins lie open in the foreground, the cadavers within in various stages of decomposition, while seven cavaliers, their horses and dogs, inspect them.

38. **Technic of Chloroformization.**—The preparations, technic of anesthetization and the accidents and measures to prevent and treat them, are listed in a large table convenient to hang up for hasty reference.

39. **Neurologic Instruction in This Country in Comparison with Europe.**—Guillain remarks that in Europe neurology is too often regarded as a special branch of medicine, rather in the line of a luxury, a superfluity that can be dispensed with, while in this country the student is expected to study it as part of the regular course. He lauds the practical way in which it is taught and the unexcelled facilities for instruction here, remarking in conclusion: "While fifteen or twenty years ago neurology did not exist in the United States or scarcely existed here, now there is such activity in it that we can foresee the day, and not very distant, when the new generations will take the rank in the international scientific movement justified by the intelligent methods of instruction and the energy in their work which distinguish the American race." Guillain has been visiting the leading medical centers from Boston to San Francisco, and draws a very attractive picture of the present status of instruction in neurology and psychiatry in the hands of our leading men, whom he cites in turn, knowing that their names are almost as familiar in Europe as at home.

40. **Estor's Method of Radical Treatment of Inguinal Hernia.**—The sac is detached as high as possible and resected without previous incision of the aponeurosis of the oblique muscle. Two wire threads are then inserted in the pillars from the front backward, crossed in the aperture of the ring and passed then through the abdominal wall, from the rear forward, emerging well above and outside of the external inguinal orifice. The entire abdominal wall, comprising all the layers, is then drawn down and fastened over the inguinal ring, forming a solid wall of muscle and aponeurosis over the inguinal ring, leaving only the opening absolutely necessary above the pubis for the emergence of the spermatic cord. Five parallel catgut or silk threads are then woven in, about 1 cm. apart, to strengthen the aponeurosis, and the skin is sutured. Estor has performed this operation 24 times. The immediate results were perfect except that in a few cases the testicle and cord appeared to be swollen for a few days, but this soon subsided without further symptoms. There was an insignificant catgut stitch abscess in three cases, but he never found it necessary to reopen the wound. The re-enforced abdominal wall is even more solid than the normal wall, and the results to date have been fine in every respect, nearly two years in his oldest cases. Eight of his patients were children. The article is accompanied by five cuts.

43. Rocking Chair for Weakly Children.—Epstein urgently recommends a low rocking chair with arms and a broad open space between the back and the seat, for children between 1 and 3 years old as a remarkably effective means of developing the muscles and especially strengthening the back. The child sits in it, facing the back, his feet hanging or touching the floor, or resting on a step made for the purpose on the long rockers. He soon learns to balance himself and rock, and, as he holds on by the back and arms, he acquires an actual military attitude, head up and spine straight, while his delight in the rocking movement inspires him to constantly renewed exercise.

50. Morbid Process in Rachitis.—Pacchioni asserts that the fundamental morbid process in rachitis is not in the bone but in the cartilage, in the protoplasm and in the nuclei of the cartilage cells.

51. Effect of Sterilization of Milk.—Cronheim publishes his research, which confirms the fact that the biologic properties of milk are impaired by the process of sterilization. The exact mechanism is not known, but clinical experiences have established that the lime metabolism is unfavorably influenced. Sterilized milk is not a suitable food for infants for long periods at a time.

52. Rare Forms of Infantile Cardiopathy.—Radioscopy explained the contradictory symptoms in the cases described. In one they were due to defective development of the septum in the common arterial trunk. The infant was 11 months old, and exhibited congenital cyanosis. The origin of the arteries was also on the opposite to the normal side, and the first portion of the aorta was rudimentarily developed, with vicarious enlargement of the pulmonary and permeable ductus arteriosus, with resulting hypertrophy of the heart. In the second case, the boy of 13 had still an opening in the ductus arteriosus, with an aneurismal dilatation of the pulmonary artery and congenital stenosis of the isthmus of the aorta. In another case a boy of 9 had an enormously hypertrophied heart, with adhesions between the pericardium and chest wall, signs of obsolete tuberculous pleurisy. The mitral and aortic valves were also insufficient, and the entire heart was displaced to the left and fastened by tuberculous bands.

55. Phosphaturia in a Child.—The little patient was a girl, not quite 5, and phosphaturia was pronounced for the nine months during which she was under observation. She suffered from helminthiasis, and there is a possibility that this fact may have had some connection with the phosphaturia

57. Oxygen in Diphtheric Stenosis.—In Hecht's experience with 9 cases of diphtheric laryngeal stenosis, the respiration was favorably affected in 2. Study of the details of these cases shows that inhalation of oxygen is always indicated when the heart action is growing weak, manifested by tachycardia. It should be kept up until the beat grows slower and, of course, be suspended if it increases the tachycardia.

58. Simultaneous Scarlet Fever and Measles.—In the epidemic of 10 cases of scarlet fever in the measles ward, it was noticed that diarrhea preceded the exanthem in 6. The fleeting character of the eruption was also noticeable and the severity of the complications. Doebert's experience warns that the simultaneous occurrence of these two diseases must be carefully guarded against.

59. Value of Systematic Lumbar Puncture in Hydrocephalus.—When the hydrocephalus is congenital, the alterations in the parts are usually so severe that merely a palliative effect is to be hoped for. But in cases of the condition following meningitis or other cause, it may be possible to realize a complete cure by this means. In one case described all symptoms of the chronic hydrocephalus had vanished by the end of eight months, during which time 283 c.c. of cerebrospinal fluid had been withdrawn in eleven punctures. In another case a boy of 2, with hydrocephalus consecutive to cerebrospinal meningitis, showed remarkable improvement until his death from an intercurrent infection. He was treated in the course of two years by lumbar puncture repeated fifteen times, with escape of 660 c.c. of fluid. Concetti repeated the puncture fifty-three times in two years in one case with marked benefit.

60. Prognosis of Gin Liver.—The postmortem findings in the case described revealed unmistakable evidence of old liver cirrhosis with atrophy, confirmed also by the history of an abrupt, stormy attack of the symptoms familiar in this affection. The man was 42 years old at the time and an immoderate drinker. He abandoned the use of alcohol on his physician's advice, and all the symptoms gradually retrogressed, until he

had clinically recovered. Thirty years later he succumbed to a rapidly developing carcinoma of the esophagus, without ever having exhibited any further symptoms of a liver affection in the interim. The liver was found adherent to the spleen and the development of collateral circulation through this organ may have been responsible for the absence of congestion and ascites. If the morbid process is arrested before all the liver tissue is destroyed, it is evidently possible for the remaining portion to compensate it and for the patient to clinically recover. Total abstinence from alcohol is the *sine qua non*. The morbid process is liable to continue even with small amounts of alcohol, and it is far more difficult for a drinking man to restrict himself to continual small amounts than to accustom himself once for all to total abstinence. Besides abstention from alcohol, small doses of digitalis and potassium iodid will be found useful, the former improving the arterial circulation through the liver and the latter stimulating the metabolism in general. Congestion in the portal region is best combated by laxative salts (Carlsbad, Marienbad, Vichy, Vittel), or by calomel. Withdrawals of small amounts of blood over the region and at the anus are also useful. The ascites should be treated by puncture, systematically repeated whenever the accumulated fluid reaches a certain amount, as only under these conditions is puncture really curative. It is very rarely that the puncture can be substituted by diuretics, although the latter should be tried and also sweat baths in certain cases. The peritonitis, which so frequently accompanies liver cirrhosis, is an important aid in the cure, as it results in adhesions which in turn aid in collateral circulation. If the congestion and ascites can not be conquered in any other way, Talma's operation should be performed. The physician should be convinced that liver cirrhosis is far from having the hopeless outlook formerly attributed to it.

62. **Technic of Microscopy.**—Sato has found that a sheet of colored glass interposed between the mirror and condensor will render the microscopic field as clear and distinct by artificial light as by daylight. The complementary color to the stained preparations is usually the best, but others are frequently equally effective. He has found gelatin paper very nearly as good as glass, and adds that unstained gelatin paper will be found a useful substitute for cover glasses.

63. **Laryngeal Tuberculosis in Pregnant Women.**—Löhnberg has had occasion to observe 5 cases of laryngeal tuberculosis in pregnant women in the course of two years. In 2 there were no indications of tuberculosis elsewhere, and in the rest and in those reported by Türk the laryngeal lesions far overshadowed the others. He has collected 21 similar cases in the literature. The evidence is in favor of the assumption that pregnancy affords a predisposition to this affection and whips into a gallop a latent process. Further, that every pregnant woman with diffuse laryngeal tuberculosis is irremediably doomed, and possibly also those with merely a single tubercle. The only treatment is the palliative use of a menthol-orthoform emulsion, but this lost its efficacy after a time in his cases, and relief was obtained with morphin and tablets of cocain alone. The only effective measure against the hopeless laryngeal tuberculosis of pregnant women is that tuberculous women should not marry, and, if married, should not conceive. Pregnant women should be carefully examined at the slightest suspicion of trouble in the throat, and should be placed in the most favorable conditions of nourishment and hygiene. In case of advanced laryngeal tuberculous lesions, extensive use of every means to allay the pain is certainly indicated.

65. **Training and Treatment of Inherited Nervous or Mental Weakness.**—Serious injury may be inflicted on a child with a hereditarily weak nervous system by even a moderate box on the ear. The concussion of the brain may have a long train of effects, especially when combined with the pain, mortification and anger usually accompanying such a scene. Plutarch used to complain that the slaves that were not good for anything else were made teachers for the children, and Martin Luther and other writers since have echoed his experience in regard to teachers. A Suabian writer named Häberle kept a record of the number of blows he received during his childhood, and he states that they reached a total of 911,527 with a cane, 124,010 with a switch and 1,151,800 boxes on the ear. At the present day the children suffer more from overtaxing of the brain than from corporal punishment. What is easy for the normal child is a direct strain on children with a nervous or mentally defective heritage. Koller found 59 per cent. of such children among 370 supposedly healthy school children, and Benda 50 per cent. in the upper grades. The mental work required of such children should be graduated to their capacity, and even physical exercise should not be allowed to fatigue them. They should have frequent but brief exercise in the open air, with rest afterward. In selecting an occupation, young people with an overburdened heredity should be guided away from those requiring much nervous or mental strain. In regard to marriage, young men showing only moderate effects of such heredity should be advised to marry young, while those with pronounced manifestations should be warned against matrimony, as the cares of married life outbalance for them its advantages. Girls of this class should marry late, not until after 24 or 25, to allow them to attain their full physical development before encountering the stress of pregnancy and childbirth. In all cases, marriage into a healthy family is indispensable. The crossing of two such morbid strains is disastrous. The above are only a few points out of Pfister's long article, which is based on his extensive experience as assistant physician to the psychiatric clinic at Freiburg.

66. **Mechanical Sterilization of Rubber Gloves.**—Experiments at Kiel have demonstrated that rubber gloves can be effectively sterilized after using by washing them, still on the hands, with soap and water for a few minutes. It is not necessary to use a brush or antiseptics. After washing them on the hands they are pulled off wrong side out and washed on this side, and filled with water to discover any crack. They are then dusted with talcum powder and wrapped separately in a sterile cloth, when they are ready for use again at any time. The tabulated tests showed that the smooth surface of the rubber does not retain germs like other substances, but allows of perfect cleansing by merely mechanical rinsing. The tests were made with staphylococci and streptococci, the colon, prodigiosus and other pathogenic bacteria.

67. **Spinalgia as Early Symptom of Tuberculous Infection.**—Petruschky has noticed that "pains between the shoulder blades" is a frequent complaint of persons who later exhibit symptoms of tuberculosis. He thinks that they have some connection with a primary tuberculous inflammation of the bronchial glands, and can, therefore, be accepted as one of the earliest signs of the infection. At a recent autopsy he discovered recent secondary infection of one apex, with evidences of old tuberculous lesions in the bronchial glands, although nothing during life had suggested the possibility of tuberculous infection, and the child had died from scarlet fever. He affirms that it is possible to detect the presence of the primary bronchial involvement by the spinalgia referred to above, the typical sensitiveness to pressure of certain vertebræ between the second and seventh dorsal. They show a trace of lordosis usually, and appear to the finger to be a little broader, softer and more elastic than their fellows. The symptom is valuable only when these spinous processes are distinctly more sensitive to pressure than the others. The diagnosis of tuberculosis was confirmed by the tuberculin test in all but 2 out of 79 cases of this spinalgia, while none of them developed a spinal affection; 32 were children under 16, and 45 were adults. In only 14 were any signs of tuberculosis to be discovered in the lungs at the time. On the other hand, spinalgia was scarcely ever observed in advanced tuberculosis. Primary infection of the bronchial glands is a more dangerous lesion than when the glands in the neck are affected, although infection from the latter is liable to spread to the bronchial glands at puberty. Petruschky is an advocate of tuberculin treatment as the most rational and certain of all means of preventing general infection from glandular lesions.

69. **Tumors of Pancreas.**—Ehrlich illustrates a case of endothelioma and of sarcoma of the pancreas, both diagnosed as an ordinary cyst. He emphasizes that the most apparently

harmless cyst in the pancreas may prove to be a malignant tumor when there is no history of trauma to explain it, and exploratory puncture should therefore be systematically avoided on account of the danger of disseminating particles of malignant tissue. Both patients died, one in a few days and the other in less than four months. The first was a woman of 57 and the second a man of 66. Neither presented the appearance of malignant disease except that they were somewhat pale and thin.

70. **The Scopolamin-Morphin Narcosis.**—Schneiderlin was the first to systematically apply this method of narcosis, and he here relates his later experiences with it. The patient is in a tranquil, drowsy state and thus is obviated the psychic shock which is frequently an important factor in the by-effects of anesthesia. Another advantage is that the anesthetizer is dispensed with, while the method is free from danger if correctly done. The susceptibility of the patient is tested by a preliminary dose which causes some delay, and the respiration must be supervised for some time after the operation. These are the only drawbacks. His technic, except for emergency cases, is as follows: He tests the patient with a preliminary dose of first .8 to 1 mg. scopolamin (hyoscin) and then 2 cg. of morphin, usually on separate days. On the day of the operation he gives .8 to 1.25 mg. of the scopolamin and 2 to 3 cg. of morphin an hour and a half before commencing the operation. If, fifteen minutes before the operation, the narcosis is not sufficiently profound, he continues with .2 to .4 mg. of scopolamin and .5 to 1 cg. of morphin. Neither of the drugs alone produces insensibility, while the combination of the two at half the dose is followed by complete anesthesia. He gives a table of a number of cases in which extensive tests of the drugs were made with several days' interval at times between them so as to exclude the influence of after-effects. He also reports some emergency cases in which he operated at once. In one, for instance, he removed the glands in the axilla from a physician. At 12:30 he gave 1 mg. Sc. and 2 cg. Morph. At 1:45 he gave .8 mg. Sc. and 2 cg. Morph. At 2:15 the insensibility was complete and the operation was commenced. A similar operation on another patient was undertaken at 1:30 after an injection at 12 of 1 mg. Sc. and 3 cg. Morph. An abdominal hernia on a third patient was treated by radical operation commencing at 2 after giving at 12:30 an injection of 1 mg. Sc. and 4 cg. Morph., and at 1:45 another of .4 mg. Sc. and 1 cg. Morph. The patient must naturally be supervised afterward until return of consciousness, that asphyxia may not follow the falling back of the tongue or blood flowing into the throat. One of his patients was left alone, contrary to directions, after extraction of teeth, and the larynx became obstructed from hemorrhage, causing a condition of asphyxia requiring artificial respiration for several hours. When this method of narcosis has failed in the hands of the few others who have reported such an experience, the failure was due to the lack of preliminary testing, or too large doses were injected, or the stage of insensibility was not waited for. Fully an hour and a quarter to an hour and a half must elapse after the first injection before complete insensibility is attained and sometimes longer. It is tested by passing a needle through the lip or sticking it in the finger tip or region of the lower lid.

71. **Suture of Femoral Vein Near Poupart's Ligament.**—Schonwerth incised the femoral vein in operating on septic lesions in the inguinal region in 3 young soldiers. Instead of ligating the vein, he sutured it at once. Notwithstanding the suppuration in the glands, the lesions healed without evident thrombosis, edema or hemorrhage. He, therefore, recommends suture instead of ligature when the suppuration is of a more or less chronic character and restricted to the glands and their vicinity, as in his cases. The after-results are much better than when the task of establishing collateral circulation is imposed on the system.

73. **Treatment of Pneumonia with Cinnamic Acid.**—Krone was Landerer's assistant at one time, and regards the treatment of tuberculosis with cinnamic acid as a valuable progress. It induces a counter-irritation at the inflamed points, attracts leucocytes to the spot and conquers the primary inflammation, with a tendency to prevent general infection. By tests on himself he established the harmlessness of this medication to his complete satisfaction, and soon queried whether it were not possible to attain equally favorable results in fibrinous pneumonia. He has thus applied it in intravenous injections, strictly according to Landerer's technic, in 18 cases. In 14 the pneumonic inflammation reacted promptly to the injection, retrogressing rapidly and smoothly and in none of the cases was there general infection. In 2 of the 4 cases in which it failed to exert a favorable influence the patients were alcoholics, with degenerated hearts. He describes several cases in detail. Krone concludes that his unfailing success in the 14 uncomplicated cases indicates that cinnamic acid has an unmistakably favorable effect on fibrinous pneumonia if administered according to rule and in the early stages. It works against the inflammation in its early phases, reduces the fever, facilitates prompt and easy resolution and thus renders the breathing easier and quieter, while it prevents general infection.

78. **Movability of Grooved Liver.**—Penzoldt has had occasion to see four cases recently in which an apparently movable tumor proved to be a part of the liver separated by a deep groove from the rest, and so movable that it could easily be pushed up into the epigastrium. He thinks it probable that this condition is comparatively frequent, but has been mistakenly diagnosed. The patients complained of discomfort during stooping or working, and the groove was visible on the outer wall of the abdomen. He recommended them to suspend all their lower garments by buttoning them to a stout waist, made like a man's vest, broad on the shoulders and without any tightness around the waist. If the disturbances had been very severe he would have ordered a bandage around the trunk and, in extreme cases, anchored the movable lobe to the abdominal wall. He found that the movability and the disturbances became less as the women took on flesh, and he, therefore, advises fattening the patients as a systematic adjuvant in treatment.

80. **Aseptic and Bloodless Extirpation of Rectum.**—Wenzel describes Witzel's method of operating in case of carcinoma of the rectum, and states that he has not lost a single patient by sepsis or collapse and has had no recurrences. The indications for operation are given by the fascia recti propria. If the carcinoma has invaded this or passed beyond it, recurrence is almost inevitable, but if it is still limited by the fascia the intervention has every prospect of success. Resection of the rectum is almost certain to be followed by extension of the malignant disease from disseminated particles, and the only advantage is the retention of the natural anus. But as the anus has lost its nerve connections, it very rarely retains its functions and, consequently, any advantage from its retention is usually delusive, while those from extirpation of the rectum as a whole, with the carcinoma closely enclosed in it as in a tight bag, are so obvious and positive that there can be no comparison between the two methods. He prepares the patient for eight to ten days with light food, leaving little residue, fluids alone the last few days, with castor oil and high enemas daily until noon of the day before the operation, after which no fluids are introduced into the rectum. Fifteen drops of tct. op. spl. are given immediately after the last injection, again at evening, the next morning and again one hour before the intervention in a cup of equal parts of tea and brandy. The region is disinfected with a daily sitz soft-soap bath, with a full bath the day before and the day of the operation. The narcosis is according to his morphin and ether by the drop method. This allows an operation of several hours' duration. A soft catheter is inserted and left permanently in the bladder, and the anus is plugged with a small tampon coated with iodin and fastened with two tiers of silver wire sutures, the ends tied in a long loop, which proves a convenient handle later. The operation comprises, 1, extirpation of the coccyx and presacral detachment of the rectum; 2, mobilization of the rectal ampulla and opening of the peritoneum; 3, detaching the anal portion after ligature of the inferior hemorrhoidal artery; 4, ligature of the middle and superior hemorrhoidal arteries in the mesorectum and its

detachment up to the flexure, and 5, amputation of the rectum and making the gluteal anus. He describes in detail the reasons for further particulars of the technic. The deaths in the experience of other operators are due, in the majority of cases, to wound infection or to collapse from hemorrhage, both of which are entirely avoided by this method. The gluteal anus works so satisfactorily by its inherent elasticity and the anatomy of the parts that nearly all his patients have been able to resume their previous occupation.

81. **Operative Intervention in Carcinoma of Rectum.**—Witzel's first gluteal anus was made seventeen years ago, to remedy a stump too short to bring down to the natural anus. The nurse in attendance was overheard to murmur to herself: "He will be surprised to find it there," and Witzel states that he has been continually surprised since at the excellent functioning of the new anus. He calls it, by the way, gluteal proctostomosis. He has not lost one of the 17 patients operated on by his method from loss of blood or sepsis, and proclaims the principle: small carcinomas, extensive operations; large carcinomas, small operations; that is, merely palliative. He laments that digital examination of the rectum on complaints of "internal hemorrhoids" was neglected until too late for a carcinoma to be operable in 80 per cent. of all that applied to him. One special advantage of his method (see above) is that if the first steps of the operation show that the growth is inoperable or more accessible through a laparotomy, these indications can be complied with before injury has been inflicted on the patient. Among the various palliative operations he has tried he prefers subsartorial colostomosis, that is, he reaches the flexure through an incision above Poupart's ligament, close to the iliac crest. The flexure is drawn out through the aperture under Poupart's ligament and under the sartorius muscle, fastened to the peritoneum and to the skin and then opened after the abdominal incision has been sutured. Still another method is to make an oblique fistula similar to his stomach fistulas which close spontaneously in a few days after the tube is removed.

86. **Symptomatology of Carcinoma of Prostate.**—Doerfler reports a case which demonstrates that a carcinoma developing in the prostate, of such extent that it grows up to the orifice of one of the ureters and breaks through into the bladder, may run its course without inducing any local symptoms, especially any disturbances in urination. The rather frequent micturition observed for a year, but without any symptoms, could scarcely be regarded as pathologic, and could readily be explained by slight hypertrophy of the prostate. The case also demonstrates that a carcinoma in the prostate may cause inflammation of both Poupart's ligaments and extend to the adjacent peritoneum, simulating a periappendicular inflammation with exudate. Evidently these inflammations were transmitted by way of the involved ureter. Differentiating points are the closer vicinity of such exudates to the ureter, possibly also the lesser participation of the general health and of the intestines in the local manifestations. The later course of the malignant disease in this case was completely dominated by the symptoms of an intermittent pyelitis, intermittent accumulations of urine in the renal pelvis. An important point for the etiology of such an intermittent hydronephrosis was the fact noted that the urine collected when the patient stood and vanished on reclining. The tumor in the prostate probably pressed on the ureter when in the erect position while it sank away in the dorsal decubitus. Death was due in this case to total anuria a few days after operation, which indicates that the chronic congestion in the ureter and renal pelvis had impaired the vitality of the kidney.

89. **New Class of Hypnotics.**—The researches of Fischer and Mering establish an intimate relation between the chemical structure and the hypnotic action of drugs. The urea group is requisite but does not suffice alone. It must be in combination with some alkyl containing carbon. The nature of the alkyl is also important. Out of the entire group answering to these conditions the chemical most powerful in its hypnotic effect while most suited for therapeutic purposes, is diethyl-malonyl-urea, which in the intensity of its action surpasses all other hypnotics hitherto known. It has a slightly bitter taste; is readily soluble and in numerous tests on dogs and in the clinic proved remarkably effective in the therapeutic dose which has been established to be .3 to .5 gm. for insomnia and 1 g in agrypnia and extreme agitation. For convenience its long name is to be supplanted by "veronal."

90. **Mercury in Liver Affections.**—Klemperer has established by the two cases he published in the January number that severe liver affections may be cured by subcutaneous injection of mercury. The effect was so striking that he assumed that the lesions in the liver must have been syphilitic, but Rosenbach protests against ascribing to syphilis every lesion cured by mercury. Their occurrence in a syphilitic is a casual coincidence in many instances. Mercury is not specific against any special virus or microbe, he asserts, but is specific in the sense that it is the means of maximal stimulation or inhibition of abnormal functioning of the liver. By subcutaneous administration we avoid the deleterious action on the intestines. Too strong intestinal reaction interferes with the effect of mercury on the liver. In future he urges that all cases of acute or subacute liver affections should be treated with mercury as soon as possible, in doses too small to be laxative, or by subcutaneous injection. Considerable or continuous fever speaks against lues.

91. **Medical Treatment of Appendicitis.**—Bäumler has treated medically 187 patients with appendicitis in the last twenty-five years; 124 were men and 63 women. The recoveries were 93.6 per cent. of the men and 90.5 per cent. of the women. The severity of some of the cases can be deduced from the fact that 9 per cent. of the men and 15 per cent. of the women were compelled to remain in the hospital (Freiburg), from 60 to 200 days. He concludes from his experience that a small proportion are doomed unless promptly operated on, but recovery is possible without surgical intervention in the overwhelming majority, even in cases of large pus collections as they may empty themselves spontaneously into the intestine, bladder or vagina and if small may be absorbed. If, after complete subsidence of the attack, local phenomena still are noted, even if only occasionally, the appendix must be removed.

99. **Manifolding Radiographs Without Plates.**—The Journal has mentioned a recent suggestion that it is possible to dispense with the plate in radiographing and make the exposure directly on the photographic paper. Schuppenhauer has found that two to four thicknesses of the paper can be used and several radiographs taken at once.

100. **Curability of Tuberculosis.**—Out of the 1,731 tuberculous subjects received at the Hohenhonnef sanatorium in Germany, 208 have been cured for three to eleven years. Of the 278 dismissed as cured, 248 have been followed. Only 40 have grown worse again, and in nearly every instance this could be directly traced to the stress of poverty or overwork. All the others are permanently well. They belong to all classes of society; some of the women have married and borne children. Some have been accepted by the life insurance companies as ordinary risks.

THE NEW ORLEANS SESSION

Description of the Crescent City and Its Environs, Points of Interest and Details of the Preparations for the Fifty-fourth Annual Session of the American Medical Association, May 5 to 8, 1903

NEW ORLEANS.

"Rede the rede of this old roof tree;
Here be trust fast, opinion free,
Knightly right hand and Christian knee;
Worth in all, wit in some,
Laughter open, slander dumb;
Hearth where rooted friendships grow,
Safe as altar, even to foe."

The Crescent City bends and turns with facile form to meet and follow the Father of Waters as it runs in each direction of the compass as it surrounds, almost, the metropolis of the south. We might, in the same breath, say cosmopolis of America, for in its many variants New Orleans bears the earmarks of a foreign people, while in its modern trends it voices the note which the whole United States is to-day sounding for progress. In many ways New Orleans deserves the commentary that she is fifty years behind the times—the truth is one of which many of the multityped population are proud.

French Market.

How can one best know New Orleans? Baedeker takes a foreign city and classifies it into hotels, restaurants, museums, picture galleries, principal streets, shopping places and suburbs, and after that one changes cars for another burg. Above all New Orleans is different. It is in this that the local color has grown into almost fame. One can not see New Orleans between trains nor over night without having a certain indigestion afterwards. It needs more than just a guide book, too, and as yet the ubiquitous cicerone is a rara avis in the Crescent City. This is hardly the place to make full description, but the intending visitor should get a mind's picture of what is before him—the medical man especially, as he deals so much in analysis and the speculative.

Let us be like the guide book for a moment, to digress as we make the reader interested; and we may not forget that we are writing to advise members of the American Medical Association who are coming to New Orleans.

ARRIVAL IN NEW ORLEANS.

The first thing to do is to find lodgment. If you have reserved accommodations through the Arrangements Committee or not, you should, on arrival, go to the Bureau of Information, at the Washington Artillery Hall, and there find your location at hotel or boarding house. If you have already received explicit notification of your location, go at once to the address sent you. The Committee on Hotels and Boarding Houses, together with the Information Bureau, will have systematic arrangements for the disposition of all comers, and the bureau will be open from 8 o'clock a. m., Monday, May 4, to the end of the session. It will help the committee if each member will write in advance, stating the number of persons in the party, men, women and children.

The Levee.

The immense crowds at the 1903 carnival were excellently disposed of, and we hope to do better by the American Medical Association.

HOTELS AND BOARDING HOUSES.

Hotel rates have been considered, on both the European and American plans. With boarding houses, it is far better to arrange for bed and breakfast and to lunch at the Artillery Hall, where lunch will be daily provided. Dinner at the famous restaurants of New

Orleans should, by all means, be considered. Many of the boarding houses on the list of the committee will only have rooms without meals, so, in writing,* specific advice should be given if meals and bath are desired with rooms. Remember that the hotels can not accommodate all Association members and their families and outside quarters must be depended on.

The following hotels have rates of $1.50 and up:

New St. Charles Hotel—Between Common and Gravier streets on St. Charles street. Headquarters of the Association. (See illustration under Association News.)

Cosmopolitan Hotel—Bourbon street, between Canal street and Customhouse street. European plan.

Commercial Hotel—Corner Royal and Customhouse streets. European plan.

Grunewald Hotel—Baronne street, between Canal and Common streets. European and American plan.

Light House at West End.

St. Charles Mansion—826 St. Charles street. European and American plan.

Denechaud Hotel—Corner Carondelet and Perdido streets. European and American plan.

The following hotels have rates of $1 and up:

Fabacher's Hotel—Royal and Customhouse streets. European plan.

Louisiana Restaurant and Hotel—Customhouse street, between Royal and Bourbon streets. European plan. A few rooms only.

Antoine's Restaurant and Hotel—713 St. Louis street, between Royal and Bourbon streets. European plan. A few rooms only.

Park View House—616 Camp street (Lafayette square).

Osborne Hotel—Carondelet and Poydras streets.

Christian Women's Exchange (ladies only)—Camp street (Lafayette square). Rooms and meals.

Hotel Bero—226 Bourbon street.

The rates at boarding houses will be $1 to $2 a day, per person, for rooms only.

United States Mint.

In taking apartments at hotels or boarding houses, state in advance who you are, member of American Medical Association, and arrange rates. This saves trouble. If any discrepancy arises, report the matter

Residences on St. Charles Avenue.

to the Bureau of Information promptly and they will take the matter up for you.

All hotels are convenient to one another and, while the headquarters of the meeting will be at the New St.

Tulane University.

Charles Hotel, the Sections are as near one hotel as another.

The center of all meetings will be at the Washington Artillery Hall, on St. Charles street, seven blocks from Canal street, the main thoroughfare. The Postoffice,

* Write to Dr. E. D. Martin, care Crescent Information Bureau, 810 Common Street, New Orleans.

Registration Bureau, Bureau of Information, General Exhibit, Scientific Exhibit, and several General Sections will be found here. A complete list of Sections and their places of meeting will be found below.

THE FRENCH MARKET.

Once housed, the visitor to New Orleans has much to see and much to do to see it all. There are old places and new places of interest. There are time-worn battlefields, bits of Spain and France of the eighteenth century, traditions galore, and tastes of Creole life and customs, both in the streets and in the shops, much behind closed doors. And where do you wish to begin?

"A line of crimson, low in a gray sky, a ball of fire resting on cypress trees. Long lagoons stretching to the

Washington Artillery Hall.

river's edge; a green, idly flowing river, with its silent cargo of sleeping ships; the levee rising against the old market place, with orange boats unloading and fishermen throwing out glistening masses of pompano and red snappers; a warm, soft air from the sea, an old building looming up into the clear light from the fog, a babble of voices, and odor of many things"—so writes a press visitor of the French Market, "the most characteristic and interesting thing to see in this queer town, built in a crescent around a masterful green river."

It is a good place to begin, for here is cosmopolis itself. The butcher may cry his trade with teutonic accent, while his neighbor truckles to his patronage in gascon French; across the road, the gentler Creole accent sweetly persuades the purchaser of excellence in wares; while yet again, not a voice's length away, Italian, Sicilian, Indian, Mexican and Cajan (Acadian) tones are heard.

A stranger in the old French Market looks askance at the coffee stands, with their primitive service, but the cleanliness, first, and the appetizing odor of the fresh crullers and French *café au lait* soon make the

Court House.

desire, which comes again the next visit. Much of New Orleans and its traditions center near the French Market, Jackson square, the old cathedral and Cabildo and, on a moonlight night, which we find in May, this *vieux carré* looks like some bit of old Provence, or Tours, transported, with all its Balzacian coloring, to act as the focus for a new Latinity in a newer world. The French quarter of New Orleans has its own traditions, but it is the legendary coloring which makes each of these the

Charity Hospital.

more *genre*. Even to-day the moss-grown courtyards harbor love cotes and, in the same old way, Cupid sends the sparrows by day and the mocking bird by night. But the ghosts of Mme. Delphine, of the Royal street haunted house, of Pere Antoine, all seem to shadow modern innovations as if the city there, at least, were part of an *ancient régime*.

The doorway of some breaking house-front tells of former splendor, in every line telling of the ancestral well-being and, perhaps, opulence. The romances lie

beyond the door, and we find them now and then; amidst poverty there rests an heirloom in some bit of ivory, carved many decades since; a bit of brass, bearing noble arms; a portrait worthy Cousin Pons' collection, a dash of color on a whitewashed wall. The casual visitor does not see all these things, but to one who loves the air, the spirit hovers everywhere in the *vieux carré*.

The very streets in the old quarter are full of the spirit of things. By night the dulcet chime of the old St. Louis cathedral times the echoing footstep of the late pedestrian, who half stops in the shadowing light, as if the very walls should render up some vibrant soul among the old traditions, as the note of some old violin

Canal Street.

is roused from a buried past by a sympathetic harmony of some companion note, which passes as it sounds.

By day the balconies bear witness to a foreign land, and beneath them old-fashioned shops invite the passer-by. In Chartres street, hard by, are the stores with birds and beasts and curios of mongrel source. In Royal and Bourbon streets are shops of antiques, of books, of masks and costumes for the carnival—

"Satans and saints and painted clowns
Meet and smile in the motley throng;
And nuns and friars in sober gowns
Lift their chants with a siren's song;
For all the world is akin, and laid
Under the spell of the masquerade."

There are historic points of interest in the old quarter and of a sort to demand some pause. The guide books must tell the detail, but the suggestion may find place here.

The Place d'Armes, now Jackson square, is the point of history for those interested, for it was in one of the old buildings nearby that the Louisiana purchase was ratified. In early times there were no handsome edifices, but a simple church, on the site of the present cathedral —in which to-day rest the remains of the early priest fathers, as well as those of Don Almonester de Roxas, the founder of charities, hospitals and leprosarium. Across the alleyways, on either side, stand the Cabildo and ancient court buildings—to-day sadly in need of care and repair.

Not far down on Royal street, which passes by the old cathedral garden, the iron fret spells the name of the "St. Louis Hotel," latterly the Hotel Royal, for many years a famous hostelry; once the state capitol building, and before the war the place where slaves were sold.

At Royal and St Peter the pink house, that of "'Sieur George," "with its stucco peeling off in broad patches, has a solemn look of gentility in rags, and stands, or, as it were, hangs about the corner of two streets, like a faded fop who pretends to be looking for employment."*

* George W. Cable's "Old Creole Days."

At Hospital and Royal streets stands the "Haunted House," which by night seems to show its ghostly character; shunned by passersby as if still the shrieks and chains might be heard, or the swish, swish of silken garments speeding through the solitary street.

In the neighborhood are the house of "Mme. Delphine," the United States mint, the archbishop's palace, the famous French Opera, and the Absinthe House, which for many years served as the afternoon and evening club for the professional men of the city, and even to-day preserves its architectural and other pristine qualities.

THE RIVER AND SHIPPING.

Canal street is one of the avenues of the world; broad, with central paved portion for cars, not obstructing traffic, it presents a fine appearance.

The beginning of Canal street at the river presents a fair idea of the local river business; the shouts of the

Haunted House.

ship's mate, whose invectives are often far more forceful than polite; the running roustabouts, the hurly burly of a varying crowd; the note of a shrill whistle, or some siren sounding down the stream; the gong of the ferry, and the sights of a levee covered with all sorts of things from barrels to bales and from boxes to huge hogsheads.

On the ferry in midstream an excellent view of the foreign shipping may be had: A long line of slanting levees, here and there broken by the expanse of some ocean liner, trimmed in red, or gray, or yellow, with smaller vessels of coastwise proportions between, the snorting of some egoistic steam tug, pushing or dragging some belated burden into port.

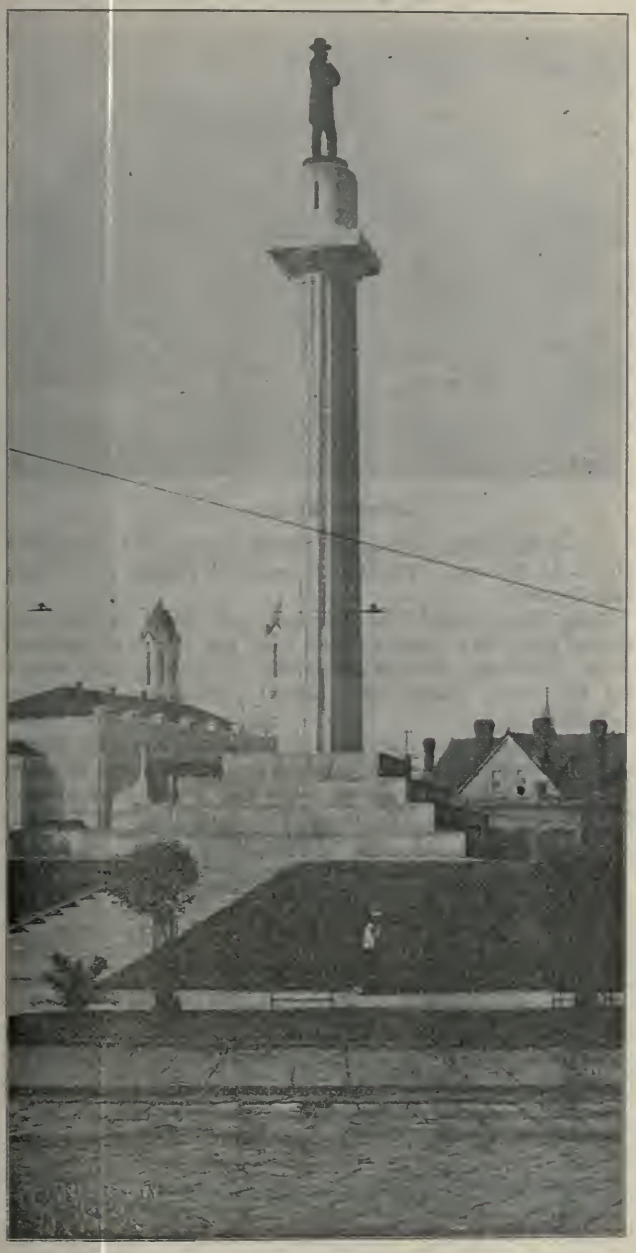
Across the stream, with a background of green cypress, two of New Orleans districts, Algiers and Gretna, lie; the former made prosperous by the Southern Pacific railroad and remaining so on its merits; the other half sleepy in its primitiveness, but kept awake by a mill or two puffing away day and night.

Yonder building, tall, on the right as your ferry comes in again, is the sugar refinery, which must be seen from the river on a foggy night to remark its

Eye, Ear, Nose and Throat Hospital.

myriad star-like windows sparkling out in the quiet darkness.

The Louisville and Nashville depot, the Fourteenth of September monument, the customhouse, a row of wholesale houses and retail stores, the Boston Club, the Chess Club, the Grand Opera House, the shopping dis-



Esplanade Street.

trict, the Pickwick Club, old Rampart street, Elk place, the court house, and, straight out Canal street all the way to the beautiful cemeteries, this broad highway runs, passing the Tulane Medical College, Claiborne avenue, the Straight University (colored), a lot of middle-class

homes, until the bayou is reached, the Half Way House and the homes of the dead. Just a bit away is the famous City Park and duelling grounds, and straight on the same electric road lies West End, the breathing spot of the city during the summer months.

This is reached through a picturesque ride past a bit of Louisiana swamp, in which the iris blooms with the dogwood, and where honeysuckle and magnolia flower together. The palms are thick among the moss-covered

Lee Circle.

trees, and the far note of the wandering crane is sometimes heard.

THE CAR LINES.

Back to Canal street again, one must be struck with the multitude of cars and the ringing of gongs. All cars center in Canal street, and the destination of each and every one is plainly marked. These are the pleasure wagons of New Orleans, and any one of the several lines will show a new part of the Crescent City.

Tulane Belt leaves Canal at Rampart, turns out Tulane avenue, passing by the court house, the New Orleans Polyclinic, and the world-famous Charity Hospital, and the Milliken Memorial Hospital for children, on and out by the baseball park and Athletic Park Casino, where, in summer, comic opera holds the boards. You round a curve and then are in Carrolton avenue for a

Richard Milliken Memorial Hospital for Children.

long and pleasant suburban spin. Then you enter the farthest extreme of St. Charles avenue, having, by a series of curves, turned until you are headed in the direction of Canal street again. This is the main uptown fashionable thoroughfare, and along it you will see every variety of southern home. You pass by Tulane University and Audubon Park, the Harmony Club, the Atheneum, Lee Circle, Howard Library, and, reaching

Audubon Park.

Canal again, have traveled a distance of about eleven miles.

St. Charles Belt covers the same ground, only moving in the opposite direction, starting from Canal and Baronne streets.

Esplanade Belt, car going away from the river, goes down Rampart street, past the Ear, Nose and Throat

Hospital, and down a double track for a distance of over a mile is a grove of trees, old as the lordly mansions lining the street on either side. This is the downtown fashionable thoroughfare, and presents the residences of the Creole families; notable in these is the home of the present mayor. Past the Jockey Club the car goes, along Bayou St. John, by the City Park, and into Canal street again and to the point of starting.

The Canal Belt makes the same circuit, in the opposite direction.

Other lines of cars,* with interesting sights, are:

CLAIBORNE AVENUE.—From the river to Claiborne. Points of interest: St. Louis cemeteries; St. Roch shrine; St. Vincent de Paul's cemeteries.

DAUPHINE LINE.—From the river to Rampart. Points of interest: Postoffice, Custom House; through the old French quarter; Ursuline convent; United States garrison; Slaughter

Cotton Exchange.

House. (This car takes you within a short walk of the Chalmette Cemetery.)

LEVEE AND BARRACKS.—Canal and Camp to North Peters. Points of interest: Postoffice and Custom House; St. Louis Cathedral; the Cabildo; the famous old French market; full view of river front; Northeastern dépot; transfers to Dauphine car at Poland, which takes you to barracks, Chalmette cemetery and Slaughter House. Also passes Jackson square and United States Mint.

PRYTANIA.—Canal and Basin to Camp. Points of interest: Margaret's monument; through resident section of the city and to Audubon Park; Howard Memorial, Howard's Library, Fisk Library, St. Patrick's Church.

MAGAZINE LINE.—From Basin and Canal out Canal to Camp, up Camp to Audubon Park. Points of interest: Boston and Pickwick clubs; through business section; Lafayette square; Fisk Free and Public Library; Margaret's Monument; Coliseum Square; St. Patrick's Church; Howard Library; Howard's Memorial; Audubon Park.

VILLERE.—From head of river, out Canal to Villere. Points of interest: Direct line to St. Roch's shrine.

TCHOUPITOULAS.—From Canal and Decatur up Tchoupitoulas to Audubon Park. Points of interest: Full view of river front; and along cotton presses; U. S. Marine Hospital; Audubon Park; also Stuyvesant docks and grain elevators.

ERATO.—Carondelet and Canal. Points of interest: New Orleans Cotton Exchange; Margaret's Monument; Annunciation and Clay Squares; Lafayette Square; City Hall; Orpheum and Audubon theaters; St. Charles Hotel; Masonic Temple.

Howard Memorial.

BAYOU ST. JOHN.—Canal and Royal, out Canal to Dauphine. Points of Interest: Passing through old French quarter and Fair Grounds.

WEST END.—Canal and Baronne, out Canal to Half-way House; along New Basin to West End; and return by the same route. Headway, summer and winter schedule varying according to travel. Points of interest: Cemeteries and Lake Pontchartrain.

NEW ORLEANS AND PONTCHARTRAIN.—From Napoleon avenue and St. Charles avenue, out Napoleon avenue to Broad; Broad to Washington avenue; Washington avenue to Carrollton avenue; Carrollton avenue to New Basin, and along the New Basin to

New Orleans Polyclinic.

the Half-way House. Returning by the same route. Points of interest: Ride through the suburbs; direct line to cemeteries.

THE RESTAURANTS.

Near Canal street and in the heart of the city is a number of points of interest to be mentioned. The famous Sazerac saloon, where cocktails are brewed, the cuisines of Lamothe's (St. Charles street near Common), of the Gem, and the Cosmopolitan restaurants on Royal and Bourbon streets are to be mentioned.

Around the corner on Custom-house, between Royal and Bourbon, the Restaurant de La Louisiane modestly

* We are indebted to the Feb. 24, 1903, edition of the N. O. Harlequin for this street car guide.

awaits you. On Bourbon street Victor affably bids you be seated and invites you to cultivate the gout he shuffles for you. The Absinthe room is just a block away at Bienville street, and it is worth while to try the poison as it is concocted by Felix.

Down by the French Opera, not far away, is Antoine's. When Jules tucks the corner of his immaculate apron in his girdle and pretends to wipe his unsoiled hand, just from his kitchen, to greet his friends' guests, he only shadows the interpretation of a gastronomic genius. There are many things at Antoine's—rather at Jules Alciatore's—to tempt Epicurean taste. Will you try a bit of cuttle fish, or a soft-shelled shrimp, a sliver of true Strasburg pâtè, a *bouillabaisse a la maitre d'hotel,* some eggs *matalengua,* a fillet in a casserole, or a chicken trussed and cooked past recognition? Jules knows how it is done. Modest withal, but sure in that art and skill which is as much deserving as the touch of a music stroke, or a tint in flesh tones on a vacant canvas.

Above Canal street, the Cotton Exchange, Board of Trade, and the theaters, five in all and in the season, prosperous enough. But sights are not hard to find.

City Park.

MEDICAL INSTITUTIONS IN NEW ORLEANS.

One always thinks of the Charity Hospital first, and really this is just, for from this old institution have arisen all of the younger hospitals and educational institutions of to-day.

In 1737 Jean Louis, sailor, bequeathed about 12,000 livres to found a hospital ("Hospice des Pauvres"), and this was the beginning of the Charity Hospital.* Subsequently Don Andres de Almonester rebuilt it, and it was subsequently destroyed in 1779. Almonester again rebuilt the hospital, the "New Charity Hospital of St. Charles," completing it in 1784, "a commodious, substantial edifice, built of brick and mortar, surrounded by suitable dependencies and provided with a chapel."

On Sept. 23, 1809, the Charity Hospital of Almonester was burned to the ground. The patients were temporarily quartered in the City Hall, afterward being removed to a country plantation, where they all but died of neglect and starvation. After a varied and tragic career, having been conceived in many sites, the New Orleans Charity Hospital arose on its present site in 1815. From that time the institution has grown in size and importance, until to-day it covers acres of ground, accommodates nearly 1,200 patients and provides facilities for the students of Tulane and of the New Orleans Polyclinic. In 1895 a new amphitheater was completed, modern in its equipment and more recently have been added a complete nurses' home and a hospital for babies and children.

The system of administration consists in a board of administrators, with a vice-president at the head (the governor of the state being the nominal president of the board). The members of this board are appointed by the governor, and have successive terms. The domestic management is in the hands of the Sisters of Charity, while the medical and surgical control is under a resident surgeon and two assistants, the interne and externe services being still further administered by a staff of undergraduates selected by competitive examination from the third-year class of Tulane.

The visiting staff have supervision of the wards and

St. Louis Cemetery.

have control of the out-door clinics, both of which are used for teaching purposes by the Polyclinic and Tulane, under provisions expressly enacted by the state legislature. Besides the Charity Hospital, the Eye, Ear, Nose and Throat Hospital and the New Orleans Polyclinic conduct free out-door clinics for the poor only; the Touro Infirmary also conducts a clinic and hospital, at which those are treated gratis who can not pay.

The Eye, Ear, Nose and Throat Hospital came into existence in 1887 as a necessitous institution for this class of patients, hitherto treated perfunctorily in a limited way at the Charity Hospital. The whole success of the institution is due to one man, Dr. A. W. de Roaldes, who has devoted himself to developing what is the best special hospital of its kind in the South.

The New Orleans Polyclinic arose contemporaneously with this hospital, originally devised to provide a post-graduate institution for upper-class students and doctors. Now in its sixteenth year, with a faculty of seventeen professors and some thirty lecturers and assistants, the Polyclinic owns a handsome building of its own and

* The early Charity Hospital, Dr. J. J. Castellanos, N. O. Med. and Surg. Journal, July, 1897.

draws a large class from the south and southwest annually. Afternoon free clinics are held in all departments.

The Touro Infirmary is a sectarian institution, doing considerable charity aside from its conduct as a private hospital. Afternoon clinics are held in all departments.

The New Orleans Sanitarium and Training School for Nurses, now erecting a new and handsome additional building, originated as a training school for nurses in 1889, the first in New Orleans and in the south. It still holds its position among the best training schools in the country while the sanitarium feature has outgrown the space and accommodations. The unsectarian character probably adds to its popularity.

The Hotel Dieu is a private hospital, owned and managed by the Sisters of Charity. The building is imposing and the institution is now very old and well known.

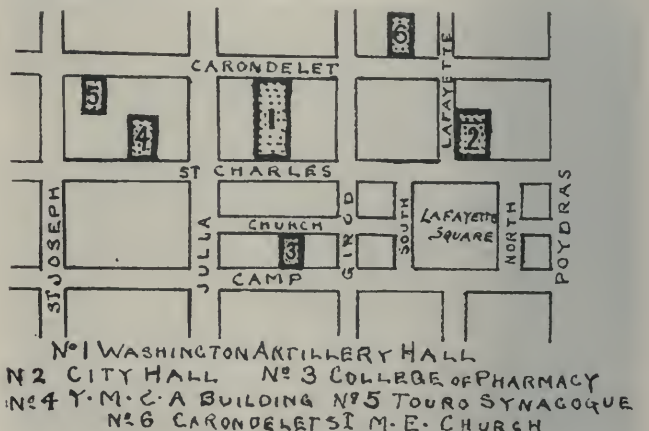
Tulane Medical College, or the Medical Department of Tulane University, has its building on Canal street, and is admirably equipped for its purposes. This department usually numbers about 400 students, chiefly from the south and southwest. The school is old and too well known to need detailed remarks. The building is known as the "Richardson Memorial," indicating the fact that it was built and donated by the widow of Dr. T. G. Richardson, at one time dean of the school and prominently connected with medical progress in the community.

The Orleans Parish Medical Society modestly holds out at 163 University Place. The rooms of the society are by no means indicative of the work accomplished by this body, which numbers about 200 members. Meetings are held twice a month and are usually full of interest.

The *New Orleans Medical and Surgical Journal* has its office at the Polyclinic. It was established in 1844 and is the fourth oldest medical journal in the United States. It is the official organ of the Orleans Parish Medical Society and the Louisiana State Medical Society.

PLACES TO FIND SOMETHING TO EAT.

Antoine's, 713 St. Louis street.
Begue's, Madison and Decatur.
Mayer's, Jackson Square.
Louisiana Restaurant, Custom House street.
Victor's, Bourbon street.
Cosmopolitan Restaurant, Bourbon or Royal, near Canal.
Lamothe's, St. Charles street, near Common.
Lopez's, Canal street.
Pizzini's, Canal street.
Domecq's, Canal street.
Janssen's, Canal street.
Brasco's, Gravier street, near Carondelet.
Vonderbanck's, Common street, near St. Charles.
Fabacher's, Royal and Custom House.
West End Hotel, West End.
Renaissance des Chenes Verts, at City Park.
Hotel Denechaud, Carondelet and Perdido.
Hotel Grunewald, Baronne, near Canal.
Commander's, Washington and Chestnut streets.
And a number of small restaurants on St. Charles avenue.



DISTRIBUTION OF SECTIONS.

1. Practice of Medicine, Washington Artillery Hall, second floor.
2 Pathology and Physiology, Washington Artillery Hall, first floor.
3. Ophthalmology, College of Pharmacy.
4. Laryngology and Otology, College of Pharmacy.
5. Surgery and Anatomy, Young Men's Christian Association, Auditorium.
6. Diseases of Children, Young Men's Christian Association.
7. Cutaneous Medicine and Surgery, Young Men's Christian Association.
8. Obstetrics and Gynecology, Touro Synagogue.
9. Nervous and Mental Diseases, Touro Synagogue.
10. Stomatology, Carondelet Street Methodist-Episcopal Church.
11. Hygiene and Sanitary Science, Carondelet Street Methodist Church.
12. Materia Medica, Pharmacy and Therapeutics, Carondelet Street Methodist-Episcopal Church.

HOUSE OF DELEGATES, Council Chamber, City Hall.
GENERAL SESSIONS, Tulane Theater.

The Washington Artillery Hall, the main building for the exhibits, postoffice, etc., was originally erected as an exposition building, and has been used for such purposes ever since. Conventions of all sorts are held here and the commodious rooms are excellently adapted. It is central and convenient to a number of car lines.

Arrangements have been made for five daily mails at the postoffice, and a news stand and telegraph and telephone station will be found there.

Location of Meeting Places.

POINTS OF INTEREST NEAR NEW ORLEANS.

The immediate suburbs of New Orleans are West End, Spanish Fort and Milneburg; West End we have already referred to. The restaurant here is one of the best in New Orleans and a delightful place to breakfast. Spanish Fort and Milneburg used to be famous resorts, but have of late years dropped into mediocrity.

Lake resorts are Covington and Mandeville, reached in a couple of hours by boat or rail.

The Louisville & Nashville runs along Mississippi Sound and touches the summer homes of the New Orleans and Mobile people. Some of these are only fishing resorts while others are well inhabited, places like Biloxi, Bay St. Louis, Mississippi City, Pass Christian and Ocean Springs being of considerable size and afforded modern convenience in the way of electric lighting and modern home facilities.

Over the Southern Pacific one quickly reaches the sugar-cane and rice countries, and in St. Mary's Parish and in the Lafourche district find the great Teche country, made classic in the beautiful references in Longfellow's Evangeline:

"Slowly they entered the Teche, where it flows through the green Opelousas."

Regular river boats make this trip in the season and the overhanging Spanish moss veritably shelters the throat-singing mocking bird, where

" . . . The line of shadow and sunshine
Ran near the top of the trees
Swinging aloft on a willow spray that hung o'er the water,
Shook from his little throat such floods of delirious music
That the whole air and the woods and the waves seemed to listen."

TRIPS TO CUBA AND ELSEWHERE.

Regular steamers run to Cuba, leaving New Orleans Saturday and reaching Havana the Monday following. Rates to Havana and return: $50 for party not less than 20; there are no steamers that can accommodate more than 60 or 80 passengers.

The Galveston steamboats no longer ply, but river boats go to Natchez and to Vicksburg, and these are interesting trips for those who wish them.

Lookout Mountain, Tennessee—Excursion rate $25, good for 90 days; if large number goes special rate will be made.

River trip to Natchez, $12 round trip; Vicksburg, $16.

Sugar-Cane Fields.

Excursion to San Antonio, Texas: Dr. J. M. Head of San Antonio has arranged a special rate of $10 for the round trip from New Orleans to San Antonio and back, if 500 members will go. Stop-over privileges will be granted for any point along the line. The entire cost round trip for 3 days, including sleeper but excluding meals, will be $17. All desiring to take advantage of this trip are urged to correspond with Dr. Head at once.

New York steamers (Cromwell line) leave New Orleans every Wednesday.

MISCELLANEOUS.

There is more than the detail of sightseeing that is interesting in New Orleans. Club life reeks with the glamour of provincial existence, and there is yet time to taste the flavor of *bien aise* after the tasks of the day are done. The stray sound of soft notes on some violin, or a gentle voice in song breathes on the night air in the springtime, and one misses quite the atmosphere of a truly great city.

Some day New Orleans will touch the higher planes of civilization, and what with modern play houses, sensational newspapers and rapid transit we may look in the near future to the destruction of some of the sentiments which still linger even in the every-day life.

Now and then the merry laugh in the tuneful voice of some gentle Creole, or the curious paraphrasing of simple English causes introspective reflection on the trend of the times, and it makes us wonder if after all the new way is really the best.

Congo Square has changed its name; the *vieux carré* is about to have the new court house and modern hotels, perhaps the postoffice, and that with the new paved streets will say good-by to the shadows which make the sentiment of the Crescent City—because they make the romances. Some old courtyards will remain, and in them the sacredness of their Latinity, but these will be like the atria of ancient Rome, full of the souvenir but barren of the spirit.

So what we may have left unsaid you will see for yourselves, for everyone makes his own pictures, and when the days are gone, besides the fruit gathered in the halls of science, we hope that you may carry away some-

Ruins at Old Spanish Fort.

thing besides the pictures and something besides the sights, for we of the Southland are like the children who beg the kindly stranger to love us just a little.

Isadore Dyer.

124 Baronne Street.

[Further announcements are made under Association News on another page of The Journal this week.]

Acute Alum Poisoning.—Dr. Julius Kramolik reports the case of a young man, aged 30, who by mistake drank a swallow of an approximately 10 per cent. solution of alum which he had prepared as a gargle for a sore throat. Neither the mouth nor the throat showed any marked reaction to the irritant, but the patient vomited thirty-nine times within the forty-eight hours following. Palpation of the stomach was painful. Mucus was found in the vomitus, mingled with blood, imparting a chocolate color to the mass. The urine was stained by blood, and showed morphologically numerous red blood cells, few leucocytes and few hyaline casts. Traces of albumin were also present. The patient was ill at least thirteen days.—*Pester Medicinisch-chirurgisch Presse.*

Books Received.

Acknowledgment of all books received will be made in this column, and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

ANATOMY OF THE BRAIN AND SPINAL CORD, with Special Reference to the Grouping and Chaining of Neurones into Conduction Paths. For Students and Practitioners. By Harris E. Santee, M.D., Ph.D., Professor of Anatomy in the College of Physicians and Surgeons; with a Preface by William T. Eckley, M.D., Professor of Anatomy in the Medical and Dental Departments, University of Illinois. Third Edition. Revised and Enlarged. Cloth. Pp. 226—xxxvi. Price, $2.00 net. Chicago: E. H. Colgrove. 1903.

A SYSTEM OF CLINICAL MEDICINE, Dealing with the Diagnosis, Prognosis and Treatment of Disease for Students and Practitioners. By Thomas D. Savill, M.D. Lond., Physician to the West End Hospital for Diseases of the Nervous System. Volume I. Local Diseases and Microbic Disorders. Cloth. Pp. 702. Price, $4.38 net. London: J. & A. Churchill. Philadelphia: P. Blakiston's Son & Co. 1903.

PHYSICAL CHEMISTRY for Physicians and Biologists. By Dr. Ernest Cohen, Professor of General and Inorganic Chemistry in the University of Utrecht. Authorized Translation from the German. By Martin H. Fischer, M.D., Instructor in Physiology in the University of California. Cloth. Pp. 343. New York: Henry Holt & Co. 1903.

A POCKET BOOK of Infant and Childhood Dietetics, with Directions for the Home Modification of Milk. [Duplicate blanks, detachable, for giving to parent or nurse.] By A. B. Spiich, A.M., M.D., Instructor in Medicine, Medical Department of the University of Illinois. Pasteboard. Price, $0.50. Chicago: E. H. Colgrove.

BACTERIA IN MILK AND ITS PRODUCTS, Designed for the Use of Students in Dairying and for All Others Concerned in the Handling of Milk, Butter or Cheese. By H. W. Conn, Ph.D., Professor of Biology. Wesleyan University. 43 Illustrations. Cloth. Pp. 306. Price, $1.25 net. Philadelphia: P. Blakiston's Son & Co. 1903.

A LABORATORY TEXT-BOOK OF EMBRYOLOGY. By Charles Sedgwick Minot, LL.D. (Yale), D. Sc. (Oxford), Professor of Histology and Human Embryology in the Harvard Medical School. With 218 Illustrations, Chiefly Original. Cloth. Pp. 380. Price, $4.50 net. Philadelphia: P. Blakiston's Son & Co. 1903.

THE ELEMENTS OF PATHOLOGICAL ANATOMY AND HISTOLOGY for Students. By Walter Sydney Lazarus-Barlow, B.A., B.C., M.D. (Camb.), F.R.C.P. (Lond.), Pathologist and Lecturer on Pathology at the Westminster Hospital. Cloth. Pp. 705. Price, $6.50. Philadelphia: P. Blakiston's Son & Co. 1903.

THE EVOLUTION OF MAN AND HIS MIND. A History and Discussion of the Evolution and Relation of the Mind and Body of Man and Animals. By S. V. Clevenger, M.D., Author of the Medical Jurisprudence of Insanity, 1898. Cloth. Pp. 615. Price, $5.00. Chicago: Evolution Publishing Co. 1903.

HYGIENE AND PUBLIC HEALTH. By Louis Parkes, M.D., D.P.H., Lond. Univ., Fellow of the Sanitary Institute and Henry Kenwood, M.B., D.P.H., F.C.S., Fellow of the Sanitary Institute. With Illustrations. Cloth. Pp. 763. Price, $3.00 net. Philadelphia: P. Blakiston's Son & Co. 1902.

THE PREVENTION OF DISEASE. Translated from the German with an Introduction by H. Timbrell Bulstrode, M.A., M.D., D.P.H. In Two Volumes. Cloth. Pp. 1,063. Net Price, $3.75 per Volume. New York: Funk & Wagnalls Company. 1903.

REPORTS OF THE SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN. Volume II, Session of 1901-1902. Edited by George Carpenter, M.D. Cloth. Pp. 310. London: J. & A. Churchill. Philadelphia: P. Blakiston's Son & Co.

MATERIA MEDICA FOR NURSES. By John E. Groff, Ph.G., Apothecary in the Rhode Island Hospital. Second Edition, Revised and Rewritten. Cloth. Pp. 169. Price, $1.25 net. Philadelphia: P. Blakiston's Son & Co. 1903.

THE MANUAL TREATMENT OF DISEASES OF WOMEN. By Gustaf Norström, M.D., of the Faculty of Stockholm. Paper. Pp. 230. Price, $2.25. New York and London: G. E. Stechert. 1903.

THE INTERNATIONAL MEDICAL ANNUAL: A Year-Book of Treatment and Practitioner's Index. 1903. Twenty-third Year. Cloth. Pp. 739. Price, $3.00. New York: E. B. Treat & Co.

CHRONIC HEADACHE AND ITS TREATMENT BY MASSAGE. By Gustaf Norström, M.D., of the Faculty of Stockholm. Paper. Pp. 59. Price, $1.00. New York and London: G. E. Stechert. 1903.

BULLETIN OF IOWA INSTITUTIONS (Under the Board of Control) January, 1903. Published Quarterly. Paper. Pp. 141. Dubuque, Iowa: Telegraph-Herald Printing Co. 1903.

TRANSACTIONS OF THE AMERICAN CLIMATOLOGICAL ASSOCIATION. For the Year 1902. Volume XVIII. Cloth. Pp. 270. Philadelphia: Printed for the Association. 1902.

SUPERIOR BOARD OF HEALTH, San Juan, P. R. Rules and Regulations for Guidance of the Health Authorities. Paper. Pp. 93. Puerto Rico: Tip. Boletin Mercantil. 1902.

PROCEEDINGS OF THE SECOND ANNUAL MEETING OF THE MEDICAL AND SURGICAL ASSOCIATION OF MISSISSIPPI at Vicksburg, Miss., April 23 and 24, 1902. Paper. Pp. 18.

REPORT OF THE COMMISSIONER OF EDUCATION for the Year 1900-1901. Volume II. Cloth. Pp. 2512. Washington: Government Printing Office. 1902.

ALBUM OF THE FELLOWS OF THE AMERICAN GYNECOLOGICAL SOCIETY, 1876-1900. Cloth. Pp. 356. Philadelphia: Wm. J. Dornan. 1901.

THE TRANSACTIONS OF THE SOCIETY OF ANESTHETISTS. Volume V. Pp. 203. London: John Bale, Sons and Danielsson, Ltd. 1903.

The Public Service.

Navy Changes.

Changes in the Medical Corps of the Navy for the week ending March 28, 1903:

P. A. Surgeon W. B. Grove, detached from treatment at Naval Hospital, New York, and ordered to duty at Naval Dispensary, Washington, D. C.

P. A. Surgeon R. W. Plummer, detached from Navy Yard, New York, and granted sick leave for three months.

Asst.-Surgeon J. F. Murphy, detached from the *Glacier* and ordered to the *Monocacy*.

Marine-Hospital Changes.

Official list of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended March 26, 1903:

Surgeon G. W. Stoner, to proceed to Washington, D. C., for special temporary duty.

Surgeon John Godfrey, Department letter of Nov. 22, 1902, granting extension of leave of absence for three months, amended so that said extension shall be for two months and twenty-five days from Dec. 13, 1902.

Surgeon F. W. Mead, granted leave of absence for five days from April 13.

P. A. Surgeon A. C. Smith, granted leave of absence for 15 days from April 8.

Asst.-Surgeon D. E. Robinson, granted leave of absence for two months and fifteen days from April 1.

Asst.-Surgeon J. W. Schereschewsky, granted leave of absence for one day.

Pharmacist R. H. Gibson, Department letter of March 18, 1903, granting leave of absence for twenty-three days, amended so that said leave shall be for eight days from March 9.

Pharmacist Carl Stier, granted leave of absence for one day, under paragraph 210 of the regulations.

PROMOTION.

Asst.-Surgeon M. H. Foster commissioned as passed assistant-surgeon to rank as such from March 11, 1903.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended March 28, 1903:

SMALLPOX—UNITED STATES.

Alabama: Mobile, March 14-21, 2 cases.
California: Berkeley, March 4-11, 1 case; Los Angeles, March 7-14, 4 cases; San Francisco, March 8-15, 6 cases.
Colorado: Denver, March 7-14, 22 cases.
Delaware: Wilmington, March 14-21, 1 death.
Florida: Jacksonville, March 14-21, 3 cases.
Illinois: Chicago, March 14-21, 12 cases.
Indiana: Elwood, Jan. 15-22, 7 cases; Indianapolis, March 7-21, 29 cases, 7 deaths.
Iowa: March 14-21, Davenport, 3 cases; Dubuque, 1 case.
Kansas: Wichita, March 14-21, 3 cases.
Kentucky: Newport, March 14-21, 1 case.
Louisiana: New Orleans, March 14-21, 4 cases, imported.
Maryland: Baltimore, March 14-21, 2 cases.
New Jersey: Camden, March 14-21, 2 cases.
New York: New York, March 14-21, 1 case.
Ohio: Cincinnati, March 13-20, 17 cases; Cleveland, March 14-21, 1 case; Hamilton, March 14-21, 1 case.
Pennsylvania: March 14-21, Altoona, 2 cases; Erie, 2 cases; Johnstown, 1 case, 1 death, imported; McKeesport, 1 case; Philadelphia, 26 cases, 1 death; Pittsburg, 29 cases, 4 deaths, imported, 3 cases.
South Carolina: Charleston, March 14-21, 5 cases, 1 death.
Tennessee: March 14-21, Memphis, 1 case; Nashville, 1 case.
Texas: San Antonio: Jan. 1-Feb. 28, 5 cases.
Utah: Salt Lake City, March 7-21, 53 cases.
Washington: Tacoma, March 1-16, 4 cases.
Wisconsin: Green Bay, March 15-22, 6 cases; Milwaukee, March 14-21, 2 cases.

SMALLPOX—FOREIGN.

Belgium: Antwerp, Feb. 14-21, 2 cases, 1 death.
Brazil: Rio de Janeiro, Feb. 20-27, 5 deaths.
France: Lyons, Feb. 21-28, 1 death; Paris, Feb. 28-March 7, 1 death.
Great Britain: Feb. 28-March 7, Dublin, 5 cases, 1 death; London, 2 cases; Manchester, 19 cases; Sunderland, 1 case.
India: Bombay, Feb. 17-24, 74 deaths; Calcutta, Feb. 14-21, 6 deaths.
Mexico: City of Mexico, March 1-8, 9 cases, 5 deaths.
Straits Settlements: Singapore, Jan. 31-Feb. 7, 1 death.
Turkey: Alexandretta, Feb. 21-28, 3 cases.

YELLOW FEVER.

Brazil: Rio de Janeiro, Feb. 20-27, 40 deaths.
Colombia: Panama, March 10-17, 3 cases, 1 death.
Ecuador: Guayaquil, Feb. 14-21, 8 deaths.

CHOLERA—FOREIGN.

India: Calcutta, Feb. 14-21, 68 deaths.
Straits Settlements: Singapore, Jan. 31-Feb. 7, 1 death.

PLAGUE—INSULAR.

Hawaii: Hilo, March 7, 2 deaths.

PLAGUE—FOREIGN.

Africa: Durban, to Feb. 23, 83 cases, 50 deaths; Pietermaritzburg, Feb. 26, 1 case.
Brazil: Rio de Janeiro, Feb. 20-27, 1 death.
India: Bombay, Feb. 17-24, 1,054 deaths; Calcutta, Feb. 14-21, 277 deaths; Mauritius, Feb. 12-19, 4 cases, 1 death.
Mexico: Mazatlan, to March 20, 313 cases, 254 deaths.

TREATMENT OF PUERPERAL FEVER.*

C. S. BACON, M.D.

CHICAGO.

The mortality from puerperal fever can be reduced to almost nothing by the proper management of labor and childbed. This has been proven by the results obtained in the best maternity hospitals. Mild cases of infection can not be entirely prevented, but they cease to be a source of great anxiety to the physician and of danger to the mother.

In private practice these encouraging results due to the aseptic management of labor are not obtained because labor is not managed aseptically. In Chicago the mortality from puerperal infection has remained about stationary for the last ten or twelve years. From 5 to 7 per cent. of all deaths of women of child-bearing age are from puerperal infection. It is probable that the same ratio holds all over the state and country. Hence it appears that puerperal infection carries off more women in the prime of life than any other disease except consumption. How much sickness not fatal is due to the same cause can be easily imagined.

These discouraging conditions are due in part, no doubt, to the fact that a considerable number of confinement cases are still in charge of incompetent midwives and women with no training whatever. So far as the responsibility of the profession is concerned the trouble is that the matter of the aseptic management of labor is not taken seriously enough. The frequently repeated observation that many women get along all right in the worst surroundings seems to create a doubt in the minds of many whether all the bother required to manage a labor aseptically is necessary. Then the frequent internal examination and the early and unnecessary operative interferences without proper preparation increase the dangers manifold. The source of all the trouble is, I believe, the failure of both the laity and the profession to recognize the importance of labor and its management. So long as obstetrics is the poorest paid department of medicine, so long will it be the most neglected.

Since the prophylaxis is unsatisfactory the treatment of puerperal fever continues to be an important subject. Ever since the demonstration of the microbic origin of this disease the principles and methods of treatment have changed considerably from time to time. At first much was expected of the antiseptic applications and irrigations. Many of you will remember that fifteen years ago sublimate vaginal and intrauterine douches were generally recommended in all cases of infection. Experience soon proved their uselessness as well as danger. Not only were serious and fatal cases of general intoxication reported, but the local effect of the solution on the vaginal and uterine tissues was detrimental. The hope of killing the germs with the microcidal solution was vain, because, as we soon learned, the sublimate had very little penetration and the great mass of bacteria was beyond its reach.

The direct application of antiseptics or caustics to the infecting germs and the dead and ulcerated tissues is possible only in the vulva, the vagina and the vaginal portion of the cervix. Here nitrate of silver, carbolic acid and other milder caustics may be applied to the well-exposed puerperal ulcers with the effect of hastening the separation of the sloughing tissue and limiting the amount of absorption of toxins and favoring and shortening the inflammatory process. If these applications be made with care so that not too much injury be done to healthy or uninvolved tissue they may be of value. We must remember that the most radical treatment can not destroy all microbes. The best we hope to do is to assist in removing contaminated and sloughing tissues. Keeping this principle in mind some effort may be made to treat antiseptically the accessible vaginal and vulvar infected wounds.

When the uterus is infected we can only hope to remove, first, decidual and placental debris in which microbes find a favorable soil for growth, and second, the toxic products which, if absorbed, caused the general systemic disturbance. Two kinds of microbic disease are generally recognized. One is a true infection, caused usually by streptococci and staphylococci, which may invade living tissues and not only produce poisons that cause general intoxication, but also injure the local tissues and by means of the circulation migrate and cause remote injuries. The other microbic disease is called a sapremia or saprophytic disease, and is due to germs that live only on dead or dying tissues. This disease is largely an intoxication from absorbed products of these saprophytes. Considerable doubt has been thrown on the reality of this distinction. First, it has been shown that in many cases diagnosed clinically as saprophytic, parasitic bacteria have been found. Secondly, supposed obligate saprophytes have been found to invade the uterus like true parasites.
